Slater's research work was predominantly concerned with glaciology; and in 1921, when he accompanied the Oxford University Expedition to Spitsbergen as glaciologist, he was able to compare the structures seen in living glaciers with those that he had observed in the drift deposits of East Anglia. The results of his Spitsbergen work were published in the *Journal of Geology* (**33**, 408; 1925), and the next year he enunciated his ideas on "Glacial Tectonics as reflected in Disturbed Drift Deposits" (*Proc. Geol. Assoc.*, **37**, 392; 1926). Between 1925 and 1932, at least fourteen papers dealing with various aspects of this theory were published. In them he described, often in meticulous detail, the structures seen in disturbed drifts and in glaciers. His theory that these drift structures were actually formed within the ice-sheets, and now represent pseudomorphs of the original glacial structures, was not readily accepted by many workers when it was first proposed. In recent years, however, the hypothesis has been viewed in a much more favourable light. The evidence that he used to support his ideas was gathered from widely scattered sources: East Anglia, Wallasey, the Isle of Man, Møens Klint and Lønstrup (Denmark), Mud Buttes and Tit Hills (Alberta), drumlins near Toronto, the Rhône Glacier, and South Africa. Much of this material was collected for his D.Sc. thesis, but unfortunately his most remarkable work is, and probably will remain, unpublished. This is his detailed measured profile along the Cromer Cliffs, plotted on a scale of 1 in. to 100 ft. (1 : 1,200). The sections, mounted together to form a continuous strip many feet in length, are now housed in the Geological Survey Library.

Those of us who were privileged to know and work with George Slater will remember him for his kindness and the sympathetic assistance he was always prepared to give. He was a first-class instructor, especially to those who were taking geology for the first time, and many recognize the debt they owe him for his encouragement.

GILBERT WILSON

NEWS and VIEWS

Chemical Engineering at Manchester : Prof. F. Morton

THE honours degree course in chemical engineering in the Department of Applied Chemistry of the College of Technology, Manchester, has been in existence since 1933, when the Chemical Engineering Section was started under Mr. W. Cowan, and since that time the Section has grown in importance both as an undergraduate and postgraduate school. With the recent expansion of the College the opportunity has been taken to raise it to the status of a separate Department of Chemical Engineering, and Prof. Frank Morton, at present professor of chemical engineering in the University of Birmingham, has been appointed to the newly created chair of chemical engineering in the University of Manchester and in the College. The Department will include fuel technology and metallurgy, and it is hoped later to include courses in nuclear engineering and corrosion engineering.

Prof. Morton graduated in applied chemistry from the Manchester College of Technology in 1930, and for a period was a member of the teaching staff of that Department, before entering industry in 1936 as research chemist to Trinidad Leaseholds, Ltd., of Trinidad. After being successively superintendent of research and development and chief chemist in the Company, he was appointed in 1948 to a readership in chemical engineering in the University of Birmingham, and in the following year became professor of chemical engineering there. Prof. Morton's research work has been concerned with the constitution of petroleum, with methods of separation of hydrocarbons, particularly in the middle-distillate boiling range, and with the mechanism of oxidation and combustion of hydrocarbons in a diesel engine. While at Birmingham he extended his investigations to the constituents of coal tar and, in particular, to a study of liquid–liquid extraction methods for the separation of tar acids and bases. He is a vice-president of the Institute of Petroleum and chairman of the Research Committee. In this latter connexion he has been concerned with co-operative research sponsored by the petroleum industry at a number of universities and with the work on the biological activity of petroleum sponsored jointly by the Institute of Petroleum and the Medical Research Council.

Linen Industry Research Association : Dr. A. J. Turner, C.B.E.

DR. A. J. TURNER, who is retiring from the post of director of research of the Linen Industry Research Association at the age of sixty-seven, has had a most distinguished career. A graduate of the Universities of London and Cambridge, his first research was done under Sir William Pope. Afterwards, working on aircraft and airship materials at the National Physical Laboratory, he was appointed in 1915 head of the Fabrics Research Section of the Royal Aircraft Factory (later Establishment). Immediately after the First World War, he became the first professor of textile technology in Manchester, holding this post until 1923, when he went to India to become director of research for the Indian Central Cotton Committee. Dr. Turner was personally largely responsible for the planning of the Committee's Bombay laboratories, and for the valuable technological reports which flowed from them in succeeding years. He returned to England to become head of the Spinning Department at the Shirley Institute, Manchester, in 1931, and remained there until he accepted in 1940 the post he is now vacating. During Dr. Turner's tenure of the directorship, the scope and volume of the work of the Linen Industry Research Association have increased enormously, and through his devoted service it has come to be accepted as the research centre of almost the whole linen industry and trade. As director, he has also represented the Association on numerous government committees. Dr. Turner's well-earned honours include the presidency of the Textile Institute (1952–54), an honorary associateship of the Manchester College of Technology (1951) and various offices of the Worshipful Company of Weavers; in 1950 he was appointed C.B.E.

Mr. D. A. Derrett-Smith

MR. D. A. DERRETT-SMITH, who succeeds Dr. Turner, has been a member of staff of the Linen Industry Research Association since 1928, head of the Chemistry Department since 1938, and has had additional duties as deputy director for the past four years. He received his early training under Prof. G. T. Morgan at the City and Guilds Technical College, Finsbury, and afterwards graduated in The Queen's University, Belfast, with first-class honours in chemical technology. During his long period of service with the Linen Industry Research Association, he has made notable contributions to the chemistry of linen processing, which have been incorporated in the modern practice of bleaching, dyeing and finishing. Mr. Derrett-Smith is well known in textile circles, and will have the good wishes of all in his responsible new post.

Division of Fisheries and Oceanography, C.S.I.R.O., Australia: Dr. G. F. Humphrey

Dr. G. F. Humphrey has been appointed chief of Division of Fisheries and Oceanography of the Commonwealth Scientific and Industrial Research Organization, Australia, in succession to Dr. H. Thompson, who retired last year because of ill-health. The headquarters of the Division are at Cronulla, New South Wales. Dr. Humphrey is senior lecturer in the Department of Biochemistry, University of Sydney, having been a member of the University staff since 1941, and the bulk of his published research papers are on marine biochemistry, a field in which he has collaborated with the Division of Fisheries. His studies outside Australia have included work at the Molteno Institute, University of Cambridge, at the Universities of Glasgow and London, and at the marine laboratories at Plymouth, England, and Roscoff, France. It is intended to give increasing attention to the physical examination of the ocean as contrasted with the studies in marine biology, which have been the major concern of the Division of Fisheries in the past; and to reflect this change in emphasis the Division has been renamed the Division of Fisheries and Oceanography. For the development of Australian fisheries more accurate and complete information is needed about the factors which lead to fluctuations in the abundance of fish in the surrounding seas; this will involve the Division in more comprehensive studies of ocean currents, temperature distribution, salinity of the sea and its content of phosphate, and the influence of these physical factors on the reproduction, growth and distribution of fish populations.

Uranium for Peaceful Uses of Atomic Energy

Replying to questions in the House of Commons on February 28 regarding President Eisenhower's offer to supply uranium for developing the peaceful uses of atomic energy, the Prime Minister said that how this offer could best be utilized by the countries of the world, individually or in association, would need careful thought. A start had already been made in the Colombo Plan and in the Bagdad Pact as well as in bilateral arrangements between Great Britain and the United States and certain countries in Africa and Asia to help them in training in the peaceful uses of nuclear energy, and he thought that their first need would be to form a nucleus of trained technicians. British supplies of uranium, he added, are very limited, and he could not hold out hopes that we could follow the lead of the United States in that respect, although we have been working closely with the United States in such matters as technical help for countries which produce uranium. He agreed that it might be wise to consider channelling these supplies through the United Nations to all countries rather than through bilateral agreements.

Industrial Uses of Nuclear Energy in Britain

In replying to questions in the House of Commons on February 22 regarding the industrial uses of nuclear energy, the Lord Privy Seal, Mr. R. A. Butler, said that the Government intends to press ahead with this new source of power. For nuclear reactors which British firms might build in foreign and overseas territories, the Atomic Energy Authority is confident that natural uranium will be available as soon as it is required. Supplies of enriched uranium are limited and must be shared between defence and civil needs, but some of the civil share will be reserved for export. The output of enriched uranium is limited by the capacity of the Authority's diffusion plant at Capenhurst, and this is being watched with a view of meeting the needs of the nation. Mr. Butler also said that the Atomic Energy Authority will supply the necessary nuclear fuel, on a rental basis, for the reactor which Associated Electrical Industries proposes to construct. The terms for this loan, which are being very carefully watched, will cover the cost of fabricating the fuel elements; a percentage of the total cost of the fuel, including an element for research and development; the cost of fuels spent during the running of the reactor; and the cost of reprocessing spent fuel elements. Associated Electrical Industries intends to make the reactor available for educational research work by a group of universities in south Britain; but while paying tribute to the public spirit of this firm, Mr. Butler asked for notice of the further question as to what the firm is paying for the information and techniques supplied by the Atomic Energy Authority. He promised to consult the Lord President of the Council as to the best means of making full information on all these arrangements available to the House of Commons.

Technical Education in Britain

The promised White Paper on Technical Education (Cmd. 9703. H.M.S.O. 1*s*. 6*d*. net) includes a review of the position of technical education in England and Wales to-day against the background of the educational system as a whole, with a short account of the role of the universities, particularly in regard to technological education. The plan now announced proposes to raise the capacity of advanced courses at technical colleges as soon as possible from 9,500 to about 15,000, and to make increasing use of 'sandwich' courses for these advanced courses, backed by an adequate system of financial aid. Students proposing to attend courses leading to a technological award will be eligible for Technical State Scholarships, and the number will be raised as these courses develop, while the Government also proposes to allow ordinary State Scholarships awarded on the results of the General Certificate of Education examinations to be held not only for honours courses at universities but also for courses leading to a technological award. The Government also proposes to develop as many as possible of the twenty-four colleges at present receiving 75 per cent grant for some of their advanced work into colleges of advanced technology, with strong governing bodies and independence appropriate to the academic level of their work, and within the framework of a five-year programme of building development to cost £70 million, with a further £15 million for equipment over the period to 1960–61, inclusive, of which £59 million is to be started during the first three years. These colleges will be expected to develop their advanced work considerably and to divest themselves of work below the advanced level, as well as to undertake a substantial amount of research.

As regards technicians, five or six of whom may be required to every technologist, and craftsmen, while the Government is prepared to take its part in providing the additional facilities for technical education required to match any rise in numbers, industry must play the leading part in increasing the output of craftsmen. Besides adjustment of the terms of apprenticeship and education to suit changing needs, the Government looks to see the numbers of boys and girls under eighteen released by employers for part-time day courses doubled; and, as industrial techniques develop, it will be for the technical colleges to provide short courses designed to explain the principles involved. The White Paper points out that it is in the national interest that more girls should be encouraged to study science or mathematics at the universities or training colleges and to take courses in technical colleges; but the Government gives no indication as to how the supply of teachers for the programme is to be found, beyond expressing the hope that industry will be ready to release yet more of its employees for part-time teaching during the day. The importance of adequate libraries in technical colleges and of co-operation between college, public and other libraries is also recognized.

The situation in Scotland is discussed separately. Here the great need is for better provision for local technical colleges run by education authorities, and the Government is ready to authorize a programme of building for technical education, to be started within the next five years, to the value of £10 million, with a further £2 million for equipment. A major increase in the recruitment of teachers will be required to man the new local technical colleges, and it is also pointed out that a further 15,000 students will be needed if Scotland is to attain proportionately even the same level of day-release students as in England to-day. As in England and Wales, much remains to be done to encourage girls with a practical or scientific bent to grasp the opportunities before them.

Notes on the United States, the U.S.S.R. and Western Europe are appended to the report, and also a report on 'sandwich' training and education from the National Advisory Council on Education for Industry and Commerce. Referring to the White Paper in the House of Commons on February 29, the Minister of Education said that the capital programme will be exempt from cuts, delays or postponements of any kind. Undue resources would not be devoted to one part of the education system, and he anticipated an early statement of the plans of the universities for the quinquennium 1957–62.

Design and Application of Small Digital Computers

The first Joint Computer Conference, sponsored by the Association for Computing Machinery, the American Institute of Electrical Engineers and the Institute of Radio Engineers, was held in December 1951 at Philadelphia, Penn., and consisted of a review of electronic and digital computers. This was followed in the two succeeding Decembers by conferences in New York and in Washington, D.C., where the problems of input–output equipment and of reliability, respectively, were discussed. Meanwhile, the Western Section of the Joint Computer Committee organized similar conferences during February 1953 and 1954 and a third during March 1955, but the only conference so far held by the Eastern Section was at Philadelphia, Pasadena, during December 8–10, 1954, the proceedings of which have now been published (pp. 92. New York: American Institute of Electrical Engineers, 1955; 3 dollars). The subject under discussion was the design and application of small digital computers, and the opening address, entitled "Small Computers in a Large World", was delivered by C. W. Adams (Massachusetts Institute of Technology), the conference chairman. Seventeen technical papers were presented, and in addition to the full texts of these papers and the discussions on them, the proceedings contains reports on three panel discussions on the following: small digital computers and business applications; redundancy checking for small digital computers; and small digital computers to assist large digital computers. Individual computers or systems dealt with include the National Cash Register Company's decimal computer (*CRC* 102-*D*), the Marchant MINIAC system, the TRADIC transistor digital computer, the Burroughs *E*101 computer, and the *IBM* 650 magnetic drum data-processing machine; many different forms and applications of magnetic drum storage are described. Of particular interest is the growing use of solid-state devices—transistors, magnetic cores and ferro-dielectrics—with their great potentialities for improved reliability, decreased power, space, heat and weight, and probably also increased capacity and decreased cost when they are utilized in quantity as components in digital computers.

Chemical Background of the Aluminium Industry

In connexion with the celebration of the centenary of the foundation of the aluminium industry by Henry Ste. Claire Deville, the Royal Institute of Chemistry has published a review entitled "The Chemical Background of the Aluminium Industry" (Monograph No. 3 of the Institute, 1955), prepared by Dr. T. G. Pearson, director of research of the British Aluminium Company. This monograph, which is a model of what such a publication should be, starts off with the raw material, no less than fourteen pages being devoted to bauxite itself. The purification of the mineral by the Bayer process is then considered, and this section provides an excellent summary of the underlying chemistry. Having now obtained the pure alumina, the smelting process is next considered, and this again is an admirable discussion. The refining of this product, for which a number of processes have been developed or suggested, completes the treatment of the normal production of the metal. Two short chapters dealing with the attempts which have been made to replace the Bayer process by the production of alumina of sufficient purity, on one hand, and by the Hall-Héroult electrolytic process on the other, both of which have their own fascinations, conclude the work.

Earthquakes during August 1955–January 1956

The two greatest earthquakes during August 1955–January 1956 attained magnitude 7½, one being on January 10 in the Tonga Islands and the other on January 16 near the coast of Ecuador; the latter caused heavy property damage at Portoviejo and at Bahia de Caraquez. Six earthquakes attained magnitude 7¼. The greatest depth of focus of any earthquake during the period was 650 km. Earthquakes from this depth occurred on August 19 at Acre, Brazil, on October 21 and 30; on January 9 in the Fiji Islands region; on October 31 near the Tonga Islands; and on January 13 in the Samoa Islands. During the period two shocks were reported felt in Great Britain. That on August 22 was at Aberdovy, Merionethshire, and that on January 10 near Derby. Some sixteen shocks were felt in the European Alps, four in Turkey, two in Haute-Saône, France, and one in Spain; on January 12 an earthquake caused heavy casualties and minor damage to property in Hungary. On January 8 an earthquake at Guerrero in Mexico caused many injuries and heavy damage to property at Acapulco, while on September 1 an earthquake in Costa Rica caused heavy damage in Toro Amarello, where ten people were killed and five hundred rendered homeless. On September 12 an earthquake of magnitude 6½ from an epicentre at lat. 32·9° N., long. 29·8° E. occurred at 06h. 09m. 29s. G.M.T. and was felt over a wide area including Egypt, Palestine and Cyprus. In the region of the Nile Delta forty-five houses were wrecked and twelve schools collapsed. Twenty people are reported to have lost their lives as a result of this earthquake, including several children who died at Daher (Cairo) kindergarten girls school.

The Morphology of the Head of the Hawfinch

THE ability of the hawfinch, *Coccothraustes coccothraustes*, to crack open the stones of cherries, damsons and olives in order to feed on the kernels is generally well known; but the modifications which are present in the structure of the head and enable this comparatively small bird to perform such a feat have apparently received little attention. The method employed to crack open the fruit stones is noteworthy because each stone is held between the mandibles and is broken solely by the force applied by the jaw muscles; and no 'artifice', such as that employed by the thrush to smash snail shells, or the woodpecker to split almond stones, is used. The behaviour of the bird when feeding on fruit-stone kernels appears to follow a definite pattern. The bird usually selects fallen fruit, apparently discarding the soft parts. Observations and photographs by R. W. Sims, of the Department of Zoology, British Museum (Natural History) (*Bull. Brit. Mus.* (*Nat. Hist.*), 2, No. 13; August 1955), show that a cherry stone is arranged in the mouth by the combined movements of the head and tongue until it is held lengthways between the mandibles at the back of the horny palate of the mouth with the suture of the stone lying in the median sagittal plane of the head. A quick snap of the jaw and the shell is neatly cracked along the suture or 'seam'. The halves of the shell are rejected and the kernel is swallowed whole, usually without being crushed. Experiments on breaking open cherry and olive stones show that pressures in the region of about 100 lb./sq. in. are required to perform this feat.

Schizaeaceae of the South of England in Early Tertiary Times

A BULLETIN of the British Museum (Natural History) by Marjorie E. J. Chandler, on the "Schizaeaceae of the South of England in Early Tertiary Times" (*Bull. Brit. Mus.* (*Nat. Hist.*), *Geol.*, 2, No. 7; 1955. Pp. 24+6 pl.; 15*s*.), describes fertile specimens of three species of each of the Schizaeaceous genera *Anemia* (= *Aneimia*) and *Lygodium* from various freshwater clays of Eocene age from Hampshire and neighbouring counties. The specimens are small fragments of lignite extracted by washing. Previously the genera were known from the European Tertiary as a few ordinary compressions, but mostly without detail. The technique (which involved modifications of the usual maceration and microtoming methods) was partly due to the late W. N. Croft. The specimens are identified by matching with corresponding bits of recent leaves, and though the information is limited by the small size of the fragments, it extends to many points and is convincing. It is pointed out that the occurrence of these ferns (characteristic to-day of the wet tropics of the Old and New World) in southern England and preserved where they grew accords with the conclusions on climates reached from the Eocene seeds. Of perhaps greater significance is that, in this work, we have a study of Tertiary plants pressed, regardless of trouble, to what seems the ultimate extent and detail the material allows.

The Field Studies Council

AFTER twelve years of existence, when it was known as the Council for the Promotion of Field Studies, this well-known society issues its annual report for 1954–55 under its shorter and new name of the Field Studies Council. The report is again a record of considerable development and, except for one disquieting feature, indicates that the activities of the field centres at Dale Fort, Flatford Mill, Juniper Hall and Malham Tarn, as well as the bird observatory at Skokholm, are now accepted as an important part of the national provision for the teaching of natural history. Bookings this year have reached the highest figure, while the quality of work done continues to improve. The disquieting feature is that, despite the intense activity at the centres, the Council remains stretched to the limit of its financial resources. The appointment of more staff and the accumulation of a small sum as reserve are essential if work is to be properly planned and developed. During the year the centres were inspected by the Ministry of Education. It is to be hoped that when the full report of H.M. Inspectors is available the position of the Council will be considerably strengthened.

Scientific Problems of Humid Tropical Regions

THE study of tropical vegetation will form the subject of an international symposium to be held in Ceylon at the University of Colombo during March 19–21 under the sponsorship of the United Nations Educational, Scientific and Cultural Organization. The symposium will be attended by specialists from Belgium, Ceylon, Great Britain, India, Indonesia, Malaya, the Netherlands, Pakistan, the Philippines and the United States. Afterwards, during March 22–24, twelve scientific workers will hold a preparatory meeting on the subject of humid tropics research in order to examine specific activities for the near future. Among the projects proposed are the production of badly needed maps of humid tropical regions, the classification of vegetation within these regions, the organization of a zoological survey of Ceylon, and the organization of a Unesco-sponsored advisory committee for humid tropics research.

University of Leeds

THE following gifts have been made to the University of Leeds: £2,500 (under deed) to the Building Fund of the Chemistry and Physics Extension, from Boots Pure Drug Co., Ltd., Nottingham; £500 a year for two years to the Department of Inorganic and Structural Chemistry, from Tootal Broadhurst Lee Co., Ltd., Manchester, for research on nuclear magnetic resonance; £700 to the Department of Physical Chemistry, from BP Trading, Ltd., London, for research; and £3,500 to the Department of Coal Gas and Fuel Industries, from the British Coke Research Association, to support research on the disposal of effluents.

The following have been appointed to lectureships in the University: Dr. P. Grosberg (textile engineering) and Dr. E. V. Truter (textile chemistry).

"Quotation of Titles of Papers in Review Articles"

DR. KENNETH M. SMITH writes: "As one of the Editors of 'Advances in Virus Research' to which Mr. N. W. Pirie makes reference in his letter in *Nature* of March 3, may I make a brief comment? As I pointed out to Mr. Pirie at the time, the only reason we had reluctantly decided to omit full titles of papers in the bibliographies was the growing disinclination of authors to supply them".

Announcements

DR. J. S. WEINER, honorary assistant director of the Medical Research Council Unit at Oxford on Climate and Working Efficiency, has been awarded the Vernon Prize for 1956 of the National Institute of Industrial Psychology. This Prize is awarded every second year to the investigator who, being a British subject and under the age of forty-five, has done, in the opinion of the Council of the Institute, the most valuable research work in the subject of industrial psychology or physiology.

THE Hinchley Medal for 1955 of the British Association of Chemists has been awarded to Mr. T. McLachlan, vice-president of the Association and also president of the Association of Public Analysts. The Medal will be presented at 6 p.m. on March 16 in the Barnes Hall of the Royal Society of Medicine, 1 Wimpole Street, London, W.1, after which Mr. McLachlan will give an address on "The Analyst—Chemist, Technician or Magician?". Visitors will be welcome to the meeting. Further information can be obtained from the British Association of Chemists, Hinchley House, 14 Harley Street, London, W.1.

PROF. F. R. WINTON, professor of pharmacology and dean of the Faculty of Medicine in University College, London, has been appointed the first visiting professor of pharmacology in the University of Sydney. The appointment has been made possible by the contributions to a special fund by pharmaceutical manufacturers in Australia whereby a guest professor of pharmacology will be invited to the University each year.

MISS N. M. GOODMAN has been appointed by the Medical Research Council to the Mapother Bequest Research Fellowship for the year 1956–57. The Fellowship is provided from a fund established by the late Mrs. B. M. A. Mapother for research in psychiatry, and is held by arrangement with the University of London at the Institute of Psychiatry, Maudsley Hospital, London.

WHEN the Inorganic Nomenclature Commission of the International Union of Pure and Applied Chemistry met last July in Zurich to consider world-wide comment on the Tentative Rules for Inorganic Nomenclature, it was able to deal with about a third of the material before it. A further session will be held in Reading in April, when it is hoped to complete the work in order that a revised document may be available for publication well before the meetings of the Union next year in Paris.

To commemorate the centenary of the discovery of mauveine by W. H. Perkin, the Huddersfield Section of the Society of Dyers and Colourists is holding an exhibition in Room 65, New Extension, of the Huddersfield Technical College during March 8–11 (Sunday excluded). The exhibition consists of four sections: dyestuffs used before Perkin's time; the discovery of mauveine and the developments made from this discovery; the process of dyestuff manufacture; and the impact of colour on women's fashions throughout the world.

A ONE-WEEK course on acoustics for aeronautical engineers will be held in the University of Southampton during April 15–21. Intended for engineers with no previous formal training in acoustics, the course will include the generation of aerodynamic noise and properties of sound waves; silencing methods and the effects of noise on people; electro-acoustic measuring techniques; and the effect of noise and vibration on aircraft structures. Further information can be obtained from D. M. A. Mercer, Physics Department, University, Southampton.

A CONFERENCE on "Chromosomes" is to be held in the State Agricultural University at Wageningen, Holland, during April 16–19. The following will read papers, which will be afterwards discussed: Prof. E. Heitz, Prof. H. D. Springall, Prof. T. O. Caspersson, Mr. N. W. Pirie, Prof. A. Gustafsson, Prof. A. Müntzing and Prof. C. D. Darlington. Further information can be obtained from Prof. R. Prakken, State Agricultural University, Wageningen, Holland.

A CONFERENCE on "Scientific Ability: its Detection and Development" will be held in the Anatomy Theatre, University College, London, on March 17. The speakers will include Prof. F. Grundy, Prof. N. F. Mott, Mr. Alec Rodger, Mr. M. A. Brimer, Prof. E. M. Delf Smith, Prof. R. M. Barrer, Mr. W. Llowarch and Mr. W. H. Dowdeswell. Further information can be obtained from the Secretary, British Social Biology Council, Tavistock House South, Tavistock Square, London, W.C.1.

THE European Section of the Research Committee of the International Gerontological Association will meet in Basle during April 4–7, when the following topics will be discussed: ageing of cells and tissues; basic chemical and physical changes in ageing tissues; adaptation to changing conditions of life; autointoxication; resistance to infection; blood circulation (vascular) disorders in ageing; ageing of the central nervous system; nutrition and old age; genetic problems of ageing; and statistical treatment in research on old age. Further information can be obtained from Prof. F. Verzar, Institute of Physiology, University of Basle.

A ONE-DAY conference on "The Development of Sandwich Courses", dealing with the future organization of technical training for young men in British industry, has been arranged jointly by the Ministry of Education and the British Association for Commercial and Industrial Education and will be held in the Royal Festival Hall, South Bank, London, S.E.1, on March 22. 'Sandwich' courses consist of alternate periods, usually three to six months each, of theoretical education in a technical college and practical training in industry, and the course usually lasts for four or five years, leading in some cases to an honours degree or its equivalent; at the end of last year some fifteen hundred students in Britain were attending such courses in engineering and applied science. Between three and four hundred delegates, directors of training and similar officials, representing the major industries in Britain, are expected to attend the conference. Admission will be by ticket, applications for which should be made to Mrs. Kelly, Organizing Secretary, British Association for Commercial and Industrial Education, 8 Hill Street, London, W.1.

DETECTION OF SEED-BORNE PARASITES IN SEEDS

By PROF. A. E. MUSKETT and DR. J. P. MALONE
Ministry of Agriculture for Northern Ireland

DETAILS of the Ulster 'Method' used for the routine examination of samples of flax seed for the presence of fungal seed-borne parasites were published in 1941[1], when the parasites mainly under consideration were *Polyspora lini* Laff., the cause of stem break and browning, and *Colletotrichum linicola* Pethybr. and Laff., the cause of seedling blight. Since then it has been shown[2] that this method can equally well be used for other seed-borne parasites of the flax crop, such as *Phoma* sp., the cause of foot rot, *Alternaria linicola* Groves and Skolko, the cause of *Alternaria* seedling blight, *Botrytis cinerea* Fr., the cause of grey mould, and *Fusarium lini* Bolley, the cause of wilt, as well as for the identification of moulds which may contaminate the seed. The method is extremely simple and consists of plating out the seeds on 2 per cent malt extract agar contained in Petri dishes, incubating the dishes at 22° C. for a period of five days and then examining the seeds for the production of colonies of the parasites. It is speedy and accurate, can be readily carried out by members of a laboratory staff trained in the elements of mycology and plant pathology, while the general technique fits in well with that used for seed purity and germination tests where it is necessary to deal with large numbers of seed samples as quickly as possible. The aim of the method is to determine with accuracy the percentage of seeds in any sample which are contaminated with the parasite in a viable condition.

In 1938 the details were published[3,4] of a laboratory method which had been devised for the routine examination of seed oat samples for contamination with *Helminthosporium avenae* Eidam, the cause of seedling blight and leaf spot in the oat crop. This method consists of plating out the seeds on damp filter paper contained in Petri dishes, submitting them to irradiation from a mercury vapour lamp, incubating at 22° C. and examining them after a period of eight days for the presence of conidia of *H. avenae* produced *in situ* on contaminated seeds. It has been used continuously since then for the examination of seed samples required for work with seed disinfection and in seed health survey investigations.

Although it has been found to be of great practical value, its general use has been handicapped by the fact that higher values for contamination are nearly always obtained when the seed samples have been stored in the laboratory for some time before examination. This has been shown to be due not to the spread of the parasite in any way from seed to seed during storage, but to the fact that the storage period conditions the fungus in some such way as to cause it to sporulate more freely. Whereas this method can be relied upon to provide accurate results for seed which has been stored for some time, it cannot be regarded as so reliable in the case of freshly harvested seed. This limitation proved to be a drawback to the use of the method for seed health survey work, and it was decided to see whether the use of the Ulster Method could be extended to cover the oat crop. As had been expected, the first results were discouraging, for in the case of some seed samples the heavy growth of moulds and bacteria rendered difficult the immediate recognition of colonies of *H. avenae*. Although it is the general practice in Northern Ireland to avoid, whenever possible, the pre-treatment of seed prior to testing in order that the results obtained may refer directly to the seed sample as received, yet this was obviously an instance demanding special consideration. The pre-treatment of seeds with a mild disinfectant such as a weak solution of chlorine has been frequently recommended for the purpose of surface sterilization[5-7], and, after further experimentation, it was found that with such pre-treatment—'Chloros' was used in this instance—much better results were obtained in the case of seed oats which were freshly harvested. It is believed that by using this modified technique an accurate assessment can now be made of the degree of contamination of an oat seed sample at any time from harvest onwards.

The Ulster Method, with this modification, has also given promising results for the determination of the degree of contamination of seed oat samples with species of *Fusarium*, the most commonly occurring of which are *F. avenaceum* (Fr.) Sacc., *F. graminearum* Schwabe, *F. nivale* Auct., *F. culmorum* (W.G.Sm.) Sacc., and *F. poae* (Peck) Wollenw. The results given for *F. nivale* have been of particular promise and it is probable that when minor difficulties, such as those which sometimes arise in distinguishing between *F. graminearum* and *F. culmorum*, have been overcome the method will be readily applicable for all species.

More recently the use of the Ulster Method has been extended to apply to the health examination of seeds of other crops, and both accurate and speedy results have been obtained in the following cases: *Phoma betae* Frank, the cause of black leg in sugar beet; *Fusarium* spp. as contaminants of the seeds of wheat and barley; *Helminthosporium sativum* Pamm., King and Bakke, the cause of foot rot of wheat and barley; *Alternaria brassicicola* (Schwein) Wiltshire, the cause of dark leaf spot of cabbage; and *Phoma lingam* (Fr.) Desm., the cause of canker of cabbage.

In all the work which has been carried out so far it has only been found necessary to apply a pre-treatment of the seed in the case of oats, when the occurrence of a copious growth of moulds is, in some cases, apt to make the identification of fungal pathogens more difficult. As already stated, any kind of pre-treatment is avoided wherever possible in order that the sample of seed may be tested as received. Where such treatment is found to be necessary, it is proposed to use the term 'Modified Ulster Method', leaving the term 'Ulster Method' to cover all those cases where no pre-treatment of the seed is applied.

With rising cultivation costs throughout the world, the need for using seeds and planting stocks of the best quality in order to obtain the highest possible yield and keep production costs as low as possible is very real[8]. For this reason it may be necessary in the future to pay more attention to seed health than has been given to this problem in the past, and the need of having techniques available for this purpose which are both speedy and accurate and capable of international acceptance is clearly of some importance. The use of such techniques will greatly facilitate the carrying out of seed health tests whether they be required for international trading, internal trading within a country or for the carrying out of seed health surveys. That seed health surveys may yield results which are both of interest and importance has already been shown by that made for the health of flax seed produced in the United Kingdom. Although other techniques may be found to be more convenient in some instances, as, for example, in the case of blind seed disease of ryegrass caused by *Phialea temulenta* Prill. and Delacr.[9], yet the Ulster Method and the Modified Ulster Method would appear to have a wide application and are likely to prove of considerable value where the measurement of seed health is achieved by the direct examination of the seed for the presence of fungal pathogens.

DOCUMENTATION OF SCIENCE

In place of the usual annual report, the International Council of Scientific Unions has this year arranged for its Abstracting Board to issue a paper by its secretary, Prof. G. A. Boutry, which was read at the International Congress on Documentation of Applied Chemistry, held in London during November 23–25. The paper describes this venture in international co-operation from its origin at an international conference on scientific abstracting which was held in Paris in June 1949, organized by the Department of Exact and Natural Sciences of the United Nations Educational, Scientific and Cultural Organization. Twenty-four countries were represented, and eight of the eleven scientific unions federated with the International Council of Scientific Unions. One of the recommendations in the Final Act emphasized the importance of establishing good co-operation between existing scientific abstracting services; another urged that all original articles appearing in scientific periodicals should include an author's abstract prepared according to an agreed set of rules; and a third recommendation proposed the establishment of a single *International Journal of Physics Abstracts*, preferably bilingual. As a result of these three recommendations, a joint commission was formed by the Council to discuss further this problem of co-operation in physics abstracting. The Commission first met in Paris on December 20, 1949, and it was at once realized that any practical measures involved the co-operation of those concerned with producing *Science Abstracts* and the *Bulletin Analytique du Centre National de la Recherche Scientifique*. A meeting between representatives of the joint commission and of these two abstracting journals was arranged in London in September 1950.

At this meeting it was agreed to urge all leading periodicals publishing original papers in physics to undertake to publish authors' summaries prepared according to rules set forth by the Royal Society and by the Unesco conference of 1949, and that these summaries, irrespective of the language in which the original papers were written, should be printed either in English or French. It was also agreed that some responsible international organization should ask the publishers of periodicals, whenever advisable, for special rates of subscriptions and, in addition, to ask the editors of important periodicals to send corrected page-proofs of their issues, or at least clippings of the synopses, to the offices of *Science Abstracts* and of the *Bulletin Analytique* at the time of going to press. Finally, the editors of these two abstracting periodicals agreed to co-operate and remain in close contact, and to speed up and increase the efficiency of their work, by whatever means they thought best; it was also agreed that some responsible permanent international organization should be able to help them if they needed such assistance. Accordingly, when the joint commission considered these proposals at its next meeting in July 1951, it decided to ask the International Council of Scientific Unions to dissolve the joint commission and constitute a Board for the International Abstracting Service, on which would be represented, besides the Council itself, the abstracting journals admitted as members (initially *Science Abstracts* and the *Bulletin Analytique*).

This suggestion was studied by Unesco and the International Council of Scientific Unions, and on May 16, 1952, it was agreed to establish such an Abstracting Board, maintained by funds originating from Unesco and the International Council and with the general secretary of the latter body as a permanent member. The Board formally began to operate on June 1, 1952, and its first general assembly met at Strasbourg in July 1953, when rules and by-laws were adopted and an executive committee appointed, the composition of which for 1953–56 is: *President*, Dr. P. Bourgeois; *Secretary*, Prof. G. A. Boutry; *Members*, Dr. E. Hutchisson, Prof. A. V. Hill and Prof. J. Wyart.

As a result of the Board's work, with the exception of a few publications printed in the United Kingdom, all periodicals containing original articles on physics and published in Australia, Belgium, Canada, France, Italy, the Netherlands, the United Kingdom and the United States have agreed to publish authors' summaries in English or French or both, written according to approved rules. Moreover, editorial co-operation has been so thorough that usually the member-journals print these summaries verbatim. Attempts to obtain the same co-operation in Scandinavian countries and in Germany continue, and the four main Japanese journals of physics have also been approached.

Fifty-five periodicals printed in the United Kingdom, the United States, the Netherlands, France, Germany, Italy, Sweden, Japan and the U.S.S.R. send to the Board or its associates, generally by air-mail, complete page-proofs, or, in a few cases, clippings of authors' summaries. In 1954 the Board arranged with the director of the Institute of Documentation of the U.S.S.R. Academy of Sciences to exchange proofs of six Russian and eight American periodicals for purposes of documentation, and this exchange started in February 1955. The proofs of the Russian periodicals are microfilmed in Paris and forwarded to the editors of the member-journals. The periodicals exchanged are as follows:

U.S.S.R.

Journal of Experimental and Theoretical Physics
Journal of Technical Physics
Communications of the U.S.S.R. Academy of Sciences
News of the U.S.S R. Academy of Sciences
Progress in the Physical Sciences
Applied Mathematics and Mechanics

UNITED STATES

American Journal of Physics
Journal of Chemical Physics
Journal of the Acoustical Society of America
Journal of Applied Physics
Physical Review
Journal of the Optical Society of America
Review of Scientific Instruments
Reviews of Modern Physics

The Board has also conducted an inquiry in twelve European countries as to the feasibility of a comprehensive Russian-to-English translating service in physics, and as an outcome of this inquiry the American Institute of Physics has announced the initiation, in November 1955, of a complete English translation of the Russian *Journal of Theoretical and Experimental Physics*.

Together with the Publication Committee of the International Union of Pure and Applied Physics, the Board has also promoted the publication of articles reviewing the work of the principal schools of research in physics in the U.S.S.R. and other Slavonic countries, and it is co-operating with the same body in the revision of the Universal Decimal Classification in physics. Steps have also been taken to facilitate the abstracting of non-periodical publications in physics.

As early as 1950 the Executive Committee of the International Council of Scientific Unions had expressed the opinion that the joint commission should be concerned with the abstracting of both chemical and physical literature, and this view was endorsed by the Council in October 1951, though later a proviso was added that work on chemical documentation should not be attempted before sufficient progress had been made in the field of physics. It was only in 1954, accordingly, that the Abstracting Board was ready to extend its activities into chemical literature, and this extension was authorized by the Council in October of that year. When notified of this decision, the International Union of Pure and Applied Chemistry, now represented on the Board by Dr. L. H. Lampitt, recommended *Chemical Abstracts* and the *Bulletin Analytique* as member-journals for chemical abstracting in English and French, respectively. These journals were unanimously elected to the Board and remain the only member-journals for chemistry. The editors of a number of important chemical periodicals have already been approached with the view of organizing the exchange of page-proofs. The International Union of Mechanics and the International Union of Biology have also expressed interest in the work of the Board, and Prof. Boutry concludes his paper with a warning that the time may be due when full-time salaried officials will be required for the work of the Board in place of honorary officials.

CONNECTIVE TISSUE AND ITS CHANGES WITH AGE

THE British Society for Research on Ageing held a meeting in the Littlewood Hall of the General Infirmary, Leeds, on January 20, under the chairmanship of Prof. R. E. Tunbridge, at which four papers were read and discussed. The first, by Dr. M. K. Keech, Dr. R. Reed and Miss M. J. Wood, dealt with the characterization of elastic tissue by means of the electron microscope. They presented evidence that the variable morphology shown by normal elastic tissue fibres from various sites indicates that elastin, the fibrous protein entity assumed to be present in all forms of elastic tissue, is a complex system, consisting of fibres coated with a dense, amorphous material. They also produced evidence that dermal collagen fibrils, either fresh or prepared substantially free from ground substance, when treated at 37° C. with alkaline buffer solutions of pH 8·8, or with periodate solution, pH 5·0, transform into structures closely resembling those in naturally occurring elastic tissue (see *Nature*, 176, 966; 1955; and *J. Gerontol.*, 10, 388; 1955). These structures stain like elastica and also are attacked by the enzyme elastase.

The so-called dense, moth-eaten fibres (*Ann. Rheumat. Dis.*, 14, 19; 1955), which result from the action of bacterial collagenase on collagen fibrils, also transform, when heated in water, to similar elastin-like structures (*J. Path. and Bact.*, in the press). The importance of these findings lies in the fact that the moth-eaten fibres are an index to the age of the collagen from which they arise. In the age range 0–20 years, collagen, when treated with collagenase, forms many such fibres. From collagen of ages 20–50 years, however, their number gradually decreases, while above the age of 50 none is produced. It is concluded, therefore, that the products of collagen breakdown become coated with a dense amorphous material to form the elastin-like structures. Apparently the coating material is present in young collagen, but gradually decreases in amount with age. Elastic fibres from ox ligamentum nuchæ, when treated with boiling 1 per cent acetic acid solution for 1 hr., are apparently devoid of collagen fibrils as judged by the electron microscope. Collagenase action, however, reveals that they still contain many short fibrils of degenerate collagen. In general, therefore, there are strong morphological grounds for believing that material resembling elastic tissue can originate from the breakdown of collagen.

In the second paper, Dr. P. F. Lloyd discussed some problems relating to the polysaccharide components of connective tissue, and dealt with these under three headings: the type of polysaccharide(s) present; the nature of the linkages binding polysaccharides to other components; and the function of the polysaccharides or polysaccharide-containing complexes. Knowledge of the first two is essential for a full understanding of the third, and all three need to be studied before the wider problems concerning the nature of the changes which occur in connective tissue on ageing can be seen in true perspective.

To facilitate work on connective tissue in general, and on elastic tissue in particular, paper ionophoretic and infra-red analytical methods have been developed. Paper ionophoresis on an apparatus fitted with 'Perspex' condensers above and below the paper appears to give excellent separations of mucopolysaccharides (potential gradient 18 V./cm.). It has been found that chondroitin sulphuric acid-A moves at a faster rate than chondroitin sulphuric acids-C and -B. The mobility of the latter polysaccharide is increased after treatment with testicular hyaluronidase. Extraction of ligamentum nuchæ with 5 per cent saline followed by fractionation leads to the isolation of chondroitin sulphuric acid-B and a hyaluronic acid, the nature of which has been demonstrated by chemical and physical methods. In addition, this elastic tissue contains probably chondroitin and also a new type of connective tissue polysaccharide which is either a sulphated hyaluronic acid or a sulphated polysaccharide containing both glucosamine and chondrosamine in approximately equal amounts.

Extraction with 10 per cent calcium chloride has led to the separation of an insoluble mucoprotein containing about 8 per cent polysaccharide. In its behaviour on treatment with elastase, it resembles elastin (0·5 per cent polysaccharide); and Dr. Lloyd expressed the opinion that it would serve as a convenient model for further enzymatic studies. The results of an examination of the action of pancreatic elastase on crude polysaccharide suggest that elastase is an oxidizing enzyme.

Dr. H. Saxl and Dr. G. N. Graham, in the third paper, gave details of an interesting histochemical and biochemical study of the Ehlers Danlos syndrome. The work has been carried out during the past five years on biopsy specimens from two patients suffering from this condition. One biopsy from each of these patients afforded the material for electron-microscope studies previously reported. Histological examination of a lesion from one of the patients (a boy aged 3½ years) showed an increased amount of elastic-staining material, paralleled by a decrease of collagen. The lesion was highly metachromatic and the periodic-acid – Schiff reaction was very positive. The elastic tissue from the lesion and that of the "apparently healthy skin" surrounding it was found to be resistant to elastase. Drs. Saxl and Graham directed attention to the fact that elastase can be inhibited by a component of normal serum. The elastase-inhibiting effect of the serum of Ehlers Danlos patients was found to be quantitatively increased over that of normal serum.

Although attempts to isolate the component or components of serum responsible for such inhibition of elastase by means of chromatography on an ion-exchange resin column have been made, the results so far obtained have been rather equivocal. However, there are indications that the inhibitory agent is a high-molecular-weight component associated with the globular serum proteins. Drs. Saxl and Graham have also made a study of the effect of the inhibitor using fresh ox ligamentum nuchæ as the elastic substrate and have found a loss of metachromasia if the enzyme, the substrate and the inhibitor are incubated together. There is, however, no loss of metachromasia if each of these components is permitted to act in turn on the ligamentum nuchæ. There is an increased susceptibility of elastic tissue to elastase in senile elastosis, and the elastic fibres of the human carotid artery and of the aorta are dissolved by elastase at a greater speed with advancing age. In the serum of patients belonging to the age-group in which there is a high incidence of arteriosclerosis, there is a reduced concentration of serum inhibitor for elastase which is related to a low concentration of the enzyme in the pancreas.

In vitro experiments have indicated that the inhibitor has a twofold biological action: first, the control of the enzyme elastase in the formation of degradation products; and secondly, the absorption of metachromatic mucoid and elastic-staining substances. From the work of Karczmar and S. M. Rose, who have shown that, *in vivo*, differential development can be correlated with inhibition, it would not seem too unlikely to suggest that the elastase inhibitor can be an essential factor in the formation of elastic fibre.

The final paper, by Dr. David Hall, dealt with the dependence of equilibria between connective tissue components on age. He said that the structural components of connective tissue are particularly resistant to metabolic reactions, but must be maintained at their normal concentration by the simultaneous presence of anabolic and catabolic enzyme systems and their appropriate inhibitors. Age changes in the susceptibility of the various structures to attack by their specific enzymes can be coupled with variations in concentration of those few enzyme systems which have as yet been identified. A full assessment of the equilibria between the various components can only be made when studies of tissue, enzyme and inhibitor from the same animal and from the same age-group are made. As a preliminary to these studies, it has been necessary to examine the chemical reactivity of the tissue components.

Alkali treatment of collagen results in the extraction of small quantities of protein under conditions which give marked production of elastin-like material when examined under the electron microscope. The protein is, in certain circumstances, rich in hydroxyproline and arginine, two amino-acids which one would expect to be extracted, if collagen were to change to elastin. In the case of young collagen, this hydroxyproline-rich material is extracted during the early period of treatment, whereas the extract from old collagen does not contain a high hydroxyproline content until longer periods of extraction have occurred.

Based on these results, and those stemming from the observations of the other workers in the group, it is possible to devise a hypothesis for a similar *in vivo* synthesis of elastin via collagen. If this is done, many of the hitherto unexplained questions concerning connective tissue can be solved: for example, the absence of an elastoblast, the variations in chemical composition of elastins of various age-groups, and the appearance of elastic staining materials which are really dissimilar, in senile elastosis and the Ehlers Danlos syndrome. It was stressed by Dr. Hall that this is only a hypothesis, but that it would act as a starting-point for the discussion of age relationships of collagen and elastin, by permitting them to be considered as a single unit rather than as two diverse structures which merely share a common site.

G. H. Bourne

NON-DESTRUCTIVE TESTING OF MATERIALS AND STRUCTURES

The French and English editions of the report* on the symposium on "Non-Destructive Testing of Materials and Structures", held in Paris in January 1954 by the Réunion Internationale des Laboratoires d'Essais et de Recherches sur les Matériaux et les Constructions, include thirty-nine papers from fourteen countries, some of the discussion and a bibliography containing references to fifty-five papers on non-destructive testing. The symposium was very largely concerned with the testing of concrete, and the scope of the report is not therefore as extensive as the title suggests. There are, however, four papers in the report, by M. Mamillan, G. Dawance, A. Moles and J. Jacquesson, of France, which deal in particular with the testing of materials other than concrete, namely, stones, rock and soils.

The three sections of the report cover vibration methods (*A*), hardness methods (*B*) and radiographic methods of test (*C*), respectively. The numbers of papers dealing with these methods vary considerably: there are twenty-six papers in section *A*, nine in section *B* and four in section *C*. The papers are prefaced by short summaries introducing the sections of the report and a general note on research matters requiring further investigation, based on a report prepared by a working-group appointed during the symposium. The summary of section *A* contains a useful review in tabular form of types and applications of resonance and pulse velocity tests with their advantages and disadvantages. Like most of the papers, however, this summary is more concerned with laboratory tests than with field-tests, and an important omission in regard to the latter is mention of the practical difficulty of measuring path-lengths sufficiently accurately in testing cast in-situ concrete structures by the pulse velocity method. Some of the statements in the second table of this summary should also be interpreted with reserve, particularly the point that the variability of the quality of the concrete within a test specimen or structure can be obtained using the pulse velocity method. This has not yet been satisfactorily established: the variability of the pulse velocity may indicate the variability of the concrete in a structure, since a reduction of the pulse velocity usually indicates a reduction in strength, but relationships between pulse velocity and strength are not closely definable in the field.

---

* International Union of Testing and Research Laboratories for Materials and Structures (RILEM). Proceedings of the International Symposium on Non-Destructive Testing of Materials and Structures. Vol. 1, pp. x+1–208; Vol. 2, pp. ii+209–404. (Paris: RILEM, 12 rue Brancion.) 2,000 fr.

The first six papers, from France, South Africa, Japan, United States and Italy, describe apparatus and techniques for measuring the elastic properties of concrete by resonance tests on laboratory specimens in longitudinal and transverse vibration. The paper by N. Stutterheim, J. P. A. Lochner and J. F. Burger (South Africa), including the results of corrosion studies on concrete and cement mortar, is of particular interest, while C. E. Kesler and Y. Higuchi (United States) also contribute a useful paper on experimental problems. The remaining seven papers on resonance tests, from Japan, France, Switzerland and Great Britain, consider the interpretation of test data. A topic common to the majority of these papers is the relationship between the elastic properties and the strength of concrete. The dynamic and static moduli of concrete are compared by J. P. Daxelhofer (Switzerland), R. H. Elvery (Great Britain) and A. Lazard (France), and further remarks on this matter are included by R. Cabarat (France), T. Takabayashi (Japan) and F. Arredi (Italy). Daxelhofer's contribution includes observations on the use of resonance tests in studying frost damage to concrete at the Lausanne Polytechnic.

The succeeding thirteen papers of section *A* are concerned with pulse velocity measurements and their interpretation. Relationships between pulse velocity and the strength of concrete are dealt with by R. Jones (Great Britain), J. Andersen and P. Nerenst (Denmark), Y. Kameda, K. Awaya and I. Yokoyama (Japan), G. Magnel and G. Huyghe (Belgium) and M. Okushima and Y. Kosaka (Japan), while some information on relationships for stones is given by M. Mamillan. Jones's paper is noteworthy as a summary of much basic research at the Road Research Laboratory, Harmondsworth, and Andersen and Nerenst give a detailed account of their experience using the condenser chronograph developed at the State Testing Laboratory, Copenhagen. These two papers and those by Kameda, Awaya and Yokoyama, by A. Voellmy (Switzerland) and by Magnel and Huyghe, will probably be the papers of most interest to readers concerned with field-work on concrete, and a paper by G. Dawance to readers concerned with field-measurements on rocks. A section in the paper by J. Chefdeville (France) on the detection of faults and cracks supplements Jones's remarks on this subject, and the detection of fire damage is considered by Andersen and Nerenst and in the joint paper by Kameda and his colleagues.

In section *B*, on hardness testing, papers are contributed from Yugoslavia, Germany, Switzerland, Brazil and France, in which countries hardness tests on concrete have received greatest attention. K. Gaede (Germany) and E. Schmidt (Switzerland), prominent workers in this field, present papers describing the use of the Franck, Einbeck and Schmidt hammers, while G. Weil (Germany) points out that the Franck hammer is favoured in Stuttgart. Papers by G. Dawance and D. Jetvic, R. Peltier and P. Meynier describe experience of the use of the Schmidt hammer in France, and P. Vassitch (Yugoslavia) discusses general problems associated with hardness tests and considers both indentation and rebound measurements. A. Voellmy compares results obtained using different types of hammer and by penetration tests, and implies that the Schmidt hammer is preferable to other types. This point is clearly a matter of controversy among workers with experience of hardness testing, however.

The four papers of section *C* describe radiographic testing techniques that are still in their infancy. With one exception—a short note by G. Huyghe (Belgium)—they deal with research in France. J. Brochard describes and discusses density measurements by gamma-radiation at the Centre Expérimentale de Recherches et d'Études du Bâtiment et des Travaux Publics and the measurement of water content by neutron bombardment. J. P. Fackler's paper is a detailed account of gamma-ray tests on concrete at the Centre Scientifique et Technique du Bâtiment for the specialist, and J. Jacquesson's paper considers a problem in the technique of measuring soil densities.

The report is a useful and informative account of progress and investigations prior to 1954. It appears that it was decided to omit some of the discussion in the report, presumably in view of the large number of papers. Presentation of a large number of papers during the symposium had the effect of reducing the time spent on discussing the difficulties attending application of the methods of test and the practical significance of field-test results obtained by them. These matters are vitally important, and determine the value and promise of existing techniques of non-destructive testing in regard to concrete construction.

A. E. SEDDON

TEXTILE INDUSTRIES IN THE UNIVERSITY OF LEEDS

REPORT FOR 1953–54

THE eightieth report, to the Worshipful Company of Clothworkers of the City of London, of the Advisory Committee of the Departments of Textile Industries and Colour Chemistry and Dyeing, University of Leeds*, covering the session 1953–54, notes that the new building to house the man-made fibres division of the Department was rapidly approaching completion. A third chair, that of textile technology, has now been instituted in the Department, and the research school in the Department of Colour Chemistry and Dyeing has been further strengthened by the appointment of an Imperial Chemical Industries, Ltd., Research Fellow. The graduates of both Departments are in keen demand by many branches of industry. In textile physics further work has been carried out on the examination of fibre surfaces by replica methods, and a study of the fine structure of keratin fibres disintegrated by various techniques has shown that super-contraction is molecular rather than fibrillar in origin. A study has been made of the pigment granules isolated from various wools and hairs, and of their location in the fibres. In textile chemistry good progress is reported in the synthesis of polypeptides and related compounds, and in the search for new cross-linking agents it was found that reductone undergoes a unique type of polymerization in aqueous solution and that the polymer so formed is deposited inside the fibres. Further work was carried out on the initiation of the polymerization of vinyl compounds inside wool fibres with persulphates, on the formation of polyacrylonitrile in wool and on suint and wool wax ; a strikingly novel approach has been developed to the problem of dimensional stability, and a mixture of fluorescent dyes has been devised which gives different colours with wool, cellulosic fibres, cellulose acetate, nylon, 'Terylene' and 'Orlon'. In textile engineering, work continued on the development of the new type of cap designed to give uniform spinning tension, on the drying of wet fibrous materials and theoretical studies on the use of felts in removing water in the manufacture of paper. In textile technology the electronic mule was being used with great success for studying the behaviour of fibres during the drafting of condensed slivers, and a comprehensive investigation was in progress on the effects of weaving tensions on cloth characteristics with special reference to rayon fabrics. Changes occurring in the setting of nylon were being studied, and further progress has been made in work on the proofing of viscose rayon against bacterial attack.

---

* Report to the Worshipful Company of Clothworkers of the City of London of the Advisory Committee on the Departments of Textile Industries and Colour Chemistry and Dyeing in the University of Leeds, for the Session 1953–54. Pp 42. (Leeds. The University, 1955.)

The Department of Colour Chemistry and Dyeing made further progress in its studies of the basic reactions of anthraquinone chemistry, completing the direct hydroxylation of *peri*-naphthalimide and the quinoxaline derived from acenaphthenequinone, and pyranthrone, *amphi-iso*pyranthrone, and 6-phenyl-*meso*benzanthrone. Other work has related to the mode of formation of the anthraquinone carbazole dyes from derivatives of 1 : 1′-dianthraquinonylamine, the reactions involved in the reconversion of sulphuric esters of reduced forms of vat dyes into the parent compounds, and on the nature of the products formed by the 'over-reduction' of indanthrone. Work on the action of Grignard reagents and dialkylcadmiums on alkylquinolinium salts was completed, and a relation found between the basic strength of anions and their orientation in nuclear substitution reactions. Work on the properties of the N-methyl-derivatives of anthraquinone–acridine dyes, the chemistry and dyeing properties of hæmatin, the colouring matter of logwood, and quantitative studies on the dyeing characteristics of chlorinated wool continued, while the dyeing of blends of wool and 'Fibrolane', and the dyeing characteristics of wool–nylon, wool–'Ardil' and nylon–'Ardil' for mixtures of acid and pre-metallized acid dyes were also investigated. Lists of publications are included.

HIGH-ENERGY PARTICLE ACCELERATORS IN THE UNITED STATES

ONE of the most noteworthy features of the International Conference on the Peaceful Uses of Atomic Energy held in Geneva last August was the series of evening lectures delivered by distinguished scientists. In particular, Prof. E. O. Lawrence's talk on August 11, in which he outlined the research programme in the United States concerned with the production of large currents of high-energy sub-atomic particles by means of accelerators, was especially interesting and provoked much discussion. The illustrated article, "High-Current Accelerators", which is contributed by Prof. Lawrence to the December 9 issue of *Science* (122, 1127 ; 1955), is based on his talk to the Geneva conference, and in it he emphasizes the importance of the problem of the production of intense beams of high-energy particles for future progress in nuclear physics. This is illustrated by the remark that the particle current has steadily decreased as the energy has increased—milliamperes for the 1940 cyclotron, microamperes for the 1943 synchrocyclotron, millimicroamperes for the present cosmotron and bevatron—and that, extrapolating on this basis, currents of only two protons per hour will be produced by accelerators giving particles of 10^{16} eV. energy. Reference is made to the work of L. H. Thomas and to the later approaches of V. Veksler and E. M. McMillan to the problem of a suitable magnetic field for a high-energy cyclotron. The basic similarity between the solutions in providing an azimuthal variation in the magnetic field to achieve focusing of the particles is pointed out.

Prof. Lawrence then describes briefly experiments that have been carried out in the Radiation Laboratory of the University of California, Berkeley, where he is director, with an electron model of a clover-leaf (this refers to the shape of the magnet pole-pieces) cyclotron. The model operated in complete agreement with theoretical expectations and showed that the Thomas-type field can provide the necessary axial and radial stability and that the accelerated electrons can stay in phase with the constant-frequency accelerating voltage. In addition to producing high currents of high-energy particles, equivalent to 300-MeV. deuterons, with very low voltages on the accelerating electrodes the clover-leaf cyclotron possessed the admirable property of easy extraction of the beam. Mention is also made of recent novel approaches that have been suggested to the problem of adapting cyclotrons and betatrons to produce high currents of high-energy particles, and these are now being put to practical test by the accelerator design group of the Mid-western Universities Research Association under the direction of Prof. D. W. Kerst.

During the past four or five years, along with the development of the clover-leaf cyclotron, the Radiation Laboratory has concentrated much effort, in collaboration with the California Research and Development Co., on the construction of a linear accelerator of the cavity-resonator type devised by L. W. Alvarez. The objective is to produce a particle accelerator capable of delivering thousands of kilowatts of high-energy protons. Details are given by Prof. Lawrence in his article of this *A*-48 linear accelerator, including the ion-injector, the beam focusing and steering magnet, the 24-Mc./s. buncher and quarter-wave accelerator already completed, and the two 48-Mc./s. resonant-cavity accelerator sections, each 20 ft. long, which are still under construction. The injector consists of an arc source, in a solenoidal magnetic field, mounted on insulators in a vacuum envelope, and a focused ion beam of up to ¾ amp. has been obtained. Deuterons are accelerated by the quarter-wave machine from 140 keV. to about 1 MeV., at which speed they enter the two resonator-cavity sections. It is hoped finally to obtain an output from the complete accelerator of ¼ amp. of 7·8 MeV. deuterons, and it is expected that the accelerator will be in operation early this year.

EFFECT OF UREA ON TRYPSIN AND ALPHA-CHYMOTRYPSIN

By Dr. J. IEUAN HARRIS*

Carlsberg Laboratorium, Copenhagen

MANY simple organic substances such as urea are known to modify the specific stereochemical configuration of protein molecules in aqueous solution, and it is now well established that the increase in intrinsic viscosity encountered when native globular proteins are dissolved in concentrated urea solutions may be interpreted in terms of an increased molecular asymmetry associated with the unfolding of polypeptide chains from their specific 'native' configurations[1]. Viscosity measurements carried out in urea solutions have thus been frequently used as an experimental index of protein denaturation[1]. A more complete characterization of such a complex and ill-defined phenomenon is, however, obtained when viscosity changes are correlated with changes in other and entirely different properties of the protein molecule measured in the same chemical environment[2]. Although such an opportunity presents itself in the case of the biologically active proteins, a survey of the literature dealing with the effect of urea on a number of proteolytic enzymes reveals that in many instances the measurement of enzymatic activity has been used as the sole criterion of denaturation[3-7].

The assumption that protein denaturation and enzymic activity are mutually exclusive phenomena can be valid only if activity measurements are carried out under conditions which are not in themselves conducive to denaturation or to a reversal of a previously established denaturation effect, and although this crucial condition was stated by Anson and Mirsky[8] in their classical studies on the reversible denaturation of proteins, it has not always received the attention that it deserves. Thus in some cases the effect of urea on an enzyme has been evaluated on the basis of activity measurements carried out by the addition of an aqueous solution of the enzyme to a substrate dissolved in urea[3,9], and in others, urea solutions of an enzyme have been assayed under conditions which involve a dilution of the urea concentration in the assay medium[3-7]. These experimental procedures frequently lead to equivocal conclusions, since the possibilities that the 'active centre' of an enzyme molecule may be shielded from urea denaturation by formation of a stabilized enzyme/substrate complex, or that an inactivated denatured molecule may be subject to reversible reactivation, are not taken into consideration.

The crucial importance of relating changes in enzymic activity to changes in one or more of the physical properties of the enzyme protein measured in the same chemical environment received further emphasis when it was shown in this laboratory[2] that urea-denatured ribonuclease retains the catalytic functions of the native enzyme. Alternative explanations therefore become possible for the results obtained in previous studies on the action of urea on chymotrypsin[3], papain[4], pepsin[5], catalase[6] and trypsin[7]. For example, in a recent communication, Viswanatha and Liener[7] report that trypsin forms a stable active system in the presence of 8·3 *M* urea at *p*H 7·6; in an endeavour to explain this apparent retention of activity, it was postulated that the native active trypsin molecule is prevented from unfolding by formation of a stable protein/urea complex. The alternative possibilities, that the enzyme retains activity in an unfolded form, or that it is reversibly unfolded in 8·3 *M* urea, are not considered, despite the fact that activity was always measured under conditions which involved a five-fold dilution of the urea concentration. In view of such considerations, the effect of urea on the enzymic activities of trypsin and α-chymotrypsin has been re-investigated.

Freshly prepared 1 per cent solutions of a dialysed, recrystallized preparation of trypsin (obtained through the courtesy of the Novo Terapeutisk Laboratorium) in the appropriate concentrations of urea (A.R. grade, recrystallized from aqueous ethanol before use, and dissolved in glass-distilled water containing 0·1 *M* potassium chloride) at *p*H 4·0, were subjected to viscosity studies in a capillary viscometer maintained at 20° (± 0·01) C. Aliquot portions of the same freshly prepared solutions were diluted twenty times with the corresponding urea solution and assayed[10] against α,N-toluenesulphonyl-L-arginine methyl ester (0·005 *M*) (*a*) in the appropriate concentration of urea, and (*b*) in aqueous solution, at *p*H 7·8 and 25°. Activities expressed as zero-order velocity constants were calculated from the initial slopes of alkali uptake curves automatically recorded by means of a Jacobsen–Léonis *p*H-stat[11]; for purposes of comparison the activity of a control aqueous trypsin solution (1·72 m*M*/min./mgm. trypsin nitrogen) is expressed as 1. The results obtained are summarized in Fig. 1.

The intrinsic viscosity of trypsin increases as a function of the concentration of urea and approaches a maximum value in 8 *M* urea; and a corresponding decrease in enzymic activity is observed when assays are carried out in the presence of the appropriate concentrations of urea. Thus, contrary to previous results[7], trypsin is not active in 8 *M* urea; and furthermore, an aqueous solution of trypsin is rapidly inactivated (75 per cent inactivation during 2 min.) in 8 *M* urea at *p*H 7·8 even in the presence of α,N-toluenesulphonyl-L-arginine methyl ester. In 4 *M* urea, where the viscosity increase is 55 per cent of the maximal, trypsin retains 48 per cent of its initial activity, and similar correlations between increase in viscosity and loss of activity are observed at other concentrations of urea. When assayed in aqueous solution, however, urea solutions of the enzyme are found to regain full activity (Fig. 1).

These results suggest that at each concentration of urea a mobile equilibrium exists between native active trypsin and unfolded inactive trypsin (cf. refs. 12 and 13); equilibrium is rapidly attained at 20° and *p*H 4, is independent of trypsin concentra-

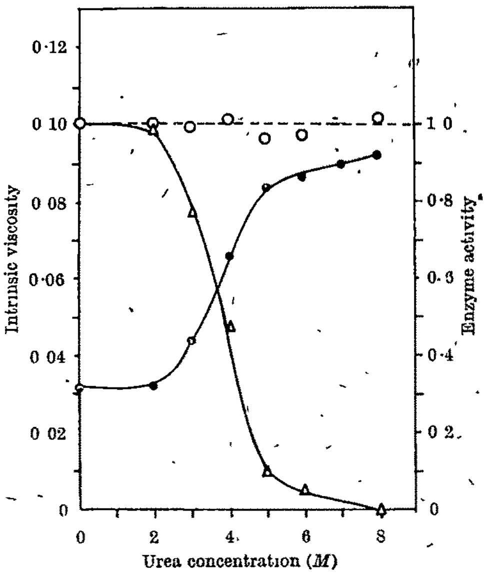

Fig. 1. Effect of urea on trypsin. ●, Intrinsic viscosity (gm./100 ml.)$^{-1}$, 1 per cent trypsin in urea *p*H 4, 20°. Esterase activity (α,N-toluenesulphonyl-L-arginine methyl ester, 0·005 *M*) *p*H 7·8, 25°. △ in urea; ○ in aqueous solution (1·72 m*M*/min./mgm. enzyme nitrogen = 1·0)

tion, and is completely reversible on dilution. In 8 *M* urea, trypsin exists entirely in a stable, unfolded inactive form which regains its former active configuration in aqueous solution. At intermediate concentrations of urea, however, the initially formed reversible equilibrium states are subject to a secondary, irreversible inactivation process which is maximal in 4 *M* urea where, according to the equilibrium hypothesis, the solution contains equimolar concentrations of active enzyme and of potential substrate in the form of unfolded enzyme molecules. Furthermore, although the composition of the equilibrium mixture is independent of the initial trypsin concentration, the kinetics of the subsequent inactivation reaction suggest that it is an enzyme-catalysed reaction which depends on residual trypsin concentration, *p*H and temperature (Harris and Linderstrøm-Lang; to be published). No increase in non-protein nitrogen could be detected (as measured by ultra-violet absorption at 280 mμ of fractions soluble in 10 per cent trichloracetic acid) in 4 *M* urea, but preliminary end-group studies are nevertheless consistent with the view that inactivation is due to a limited enzyme-catalysed autolysis at *p*H 4. Similar explanations have been proposed[12,13] to account for the irreversible inactivation of trypsin in neutral and alkaline aqueous solutions, and for the enhanced autolysis of trypsin in 4 *M* urea at *p*H 7·6[7].

In the case of α-chymotrypsin (recrystallized, salt-free preparation), viscosity studies were carried out on 1 per cent solutions at *p*H 5·0 and 20°, and enzyme activities were determined by the esterase procedure[10] (L-tyrosine ethyl ester, 0·02 *M*, *p*H 7·8, 25°). Results are summarized in Fig. 2. The viscosity of chymotrypsin increases sharply as a function of urea concentration, and the close correlation between increase in viscosity and loss of enzyme activity suggests that α-chymotrypsin also forms equilibrium mixtures of native active molecules and unfolded inactive molecules in urea solutions.

At *p*H 5 and 20° equilibrium is attained very rapidly; but in contrast to trypsin the extent of unfolding is markedly influenced by *p*H. Thus in 4 *M* urea at *p*H 5·0, chymotrypsin appears to exist entirely in the native state and retains full activity when assayed in the presence of 4 *M* urea at *p*H 7·8. At *p*H 4·0, on the other hand, an equilibrium mixture is formed which contains about 30 per cent of unfolded inactive molecules and the extent of unfolding increases further as the *p*H is lowered. In addition, the equilibrium which is rapidly established in urea solutions at *p*H 5 and 20° is not reversed to any appreciable extent in the presence of substrate in aqueous solution at *p*H 7·8 and 25°, that is, under conditions which lead to quantitative recovery of activity in the case of trypsin. Equilibrium mixtures of chymotrypsin are also subject to a secondary, irreversible enzyme-catalysed inactivation reaction; for example, although chymotrypsin is initially 80 per cent active in 5 *M* urea, the activity is reduced to 40 per cent on standing for 30 min. at *p*H 5·0 and 20°.

From the results of this investigation, it may be concluded that, unlike ribonuclease[2], trypsin and chymotrypsin do not retain activity in an unfolded form, and that covalent cross-linkages are in themselves not sufficient to maintain the integrity of the specific geometrical configurations which are essential for catalytic activity. Nevertheless, for practical purposes it is possible to take advantage of the fact that both enzymes are stabilized to a considerable extent against urea inactivation in the presence of a substrate, and can thus be used to degrade proteins which are themselves susceptible to denaturation in urea but which resist digestion in their native configurations[14,15]. The well-known hæmoglobin assay procedures for both trypsin[16] and chymotrypsin[8] are in fact based on this principle, while, more recently, similar considerations were found to apply in the case of carboxypeptidase[17].

I wish to thank Prof. K. Linderstrøm-Lang and Dr. M. Ottesen for their stimulating interest, helpful suggestions, and generous hospitality, and Dr. W. F.

STRUCTURE OF SMALL VIRUSES

IT is a striking fact that almost all small viruses are either rods or spheres. The purpose of this article is to explain this observation by means of the following simple hypothesis: a small virus contains identical sub-units, packed together in a regular manner. It has been suggested before[1] that viruses are constructed from sub-units; but the idea has not previously been described in precise terms or put forward as a general feature of all small viruses.

We believe that there is conclusive evidence for this hypothesis in two cases and suggestive evidence in a number of others. As most of the present evidence comes from the plant viruses, we shall restrict our discussion to these, except for a few remarks on animal viruses at the end of the article.

Plant Viruses

Notice first that all plant viruses which have been studied carefully are extremely regular in their shape and size[2]. In electron micrographs their dimensions are constant. One particle of turnip yellow mosaic virus, for example, is the same size as another, to within the errors of measurement. Moreover, the 'spherical' viruses have shapes very close to that of a sphere—there seem to be no ellipsoidal plant viruses. All cases where they have appeared as flattened spheres have been shown to be due to the surface tension caused by drying prior to electron microscope examination. In good photographs there are sometimes suggestions that the 'spheres' are more nearly regular polyhedra, which, as we shall see, is what one might expect.

The great regularity of plant viruses is shown even more strikingly by their ability to form crystals (or paracrystals) which give good X-ray photographs[3], often with reflexions extending to small spacings. From this we can infer that a very high degree of order exists within such viruses, and that, to a resolution almost at the atomic level, one virus particle appears identical, or at least very similar, to all its sister virus particles. A plant virus can thus be considered a 'molecule' in the sense used by protein crystallographers—an entity, the major part of which has its atoms arranged in definite (relative) positions in space.

All known plant viruses consist of two chemical components only: protein and ribonucleic acid. It seems likely that there is a general plan for their relative positions and that the majority of the protein lies on the outside of the virus, surrounding a central core composed largely, if not entirely, of ribonucleic acid. This arrangement is well established for only two viruses—the spherically shaped turnip yellow mosaic virus (by Markham[4]) and the rod-shaped tobacco mosaic virus (by both the Tubingen[5] and Berkeley groups[6])—but we believe that it is likely to apply to all simple viruses. That is, the protein component of a round virus is a spherical shell, and of a rod-shaped virus, a cylindrical shell. Our hypothesis is that in both cases these shells are constructed from a large number of identical protein molecules, of small or moderate size, packed together in a regular manner. Our hypothesis may apply, though in a slightly different form, to the ribonucleic acid component. This is discussed in more detail later.

Tobacco Mosaic Virus

This rod-shaped virus is the best studied and we shall therefore consider its structure in detail.

Tobacco mosaic virus contains 94 per cent protein and 6 per cent ribonucleic acid[7]. The characteristic particle, which is closely connected with the infectivity, has a 'molecular weight' of about 45 million, a length close to 3000 A. and a diameter of about 170 A. The early X-ray work[3] showed clearly that this particle is made up of sub-units of some sort. More recently it was realized that the basic feature of the structure is its helical nature[8]. The protein part of the virus is constructed from a large number of structurally equivalent sub-units (small globular proteins) set in helical array about the central axis. The pitch of the helix is 23 A. The number of sub-units per turn is more difficult to establish—the most probable value (Franklin, R. E., and Holmes, K. C., personal communication) gives a molecular weight for the sub-unit of about 20,000.

A very similar value is suggested by the chemical evidence. Harris and Knight[9] first examined the carboxyl end-groups of the polypeptide chains, and found that the virus particle had about 2,500 terminal groups, all threonine. This suggested that the virus contains 2,500 identical polypeptide chains, an idea which has been further strengthened by the recent work of both the Tubingen[10] and Berkeley[11] groups, who have identified the terminal three residues at the carboxyl end of this polypeptide chain.

Some additional feature is obviously needed to determine the length of the protein shell, and we would guess that in the intact virus this is controlled by the length of the ribonucleic acid core. This would explain why rods of indefinite length are produced when undenatured protein sub-units are re-aggregated in the absence of ribonucleic acid[12]. Moreover, when the re-aggregation occurs in the presence of ribonucleic acid, it is reported by Fraenkel-Conrat and Williams[13] that rods of 3000 A. in length occur very frequently.

The structure of tobacco mosaic virus, then, is based on a helix, or, in other words, it has a screw axis—in this case[8] a non-integer screw axis. This symmetry axis implies that all the protein sub-units in the body of the virus have the same environment. The same contact points between neighbouring sub-units are used over and over again as we move along the helix. This feature is the clue to the general principle which we can apply whenever, on the molecular level, a structure of a definite size and shape has to be built up from smaller units; namely, that the packing arrangements are likely to be repeated again and again—and hence that the sub-units are likely to be related by symmetry elements.

So far we have been mainly concerned with the protein, and have neglected the ribonucleic acid component of the virus. Is that, too, made up of sub-units? The ribonucleic acid content of tobacco mosaic virus is rather low, and not more than four nucleotides can be associated with a given protein sub-unit. Now if all these groups were identical, the analytical composition of the ribonucleic acid would be based on the number 4, which it certainly is not[14]. Moreover, the ribonucleic acid is probably connected with the genetic properties of the virus, and so its fundamental unit must contain a much larger number of nucleotides.

This does not mean, however, that ribonucleic acid sub-units do not exist, since it is possible that the ribonucleic acid core contains a number of identical strands systematically interacting with the protein shell. The important consideration is that the packing arrangement should be repeated over and over again; and this can be done if the symmetry of the ribonucleic acid is the same as the symmetry of the protein and if the symmetry applies only to the sugar-phosphate backbone and not to the sequence of bases. It remains to be seen whether this type of arrangement can be established experimentally.

Spherical Plant Viruses

We have seen that the rod-shaped helical form of tobacco mosaic virus represents a natural way of constructing a large container from identical much smaller building blocks. The question we must now ask is whether the protein shell of the spherical viruses is likewise constructed by a regular aggregation of one type of small protein molecule, and, if so, how this is done. Unfortunately, there has been, to our knowledge, no systematic chemical search for the presence of sub-units in spherical viruses and so we must rely almost completely on crystallographic evidence.

It has been shown in two cases—bushy stunt virus[15] and turnip yellow mosaic virus[16]—that spherical viruses crystallize in a unit cell which has the shape of a cube; but unfortunately the X-ray photographs did not establish whether the symmetry also was cubic. This is important because, as has been pointed out by Dr. Dorothy Hodgkin[1] and Dr. Barbara Low[1], if the lattice possesses true cubic symmetry so must the virus particle, since there is only one particle in the primitive unit cell.

It has now been clearly established by Caspar (see following communication) that the unit cell of bushy stunt virus has cubic symmetry, and that, in this particular case, the virus has an even higher symmetry than the unit cell. Though this evidence applies to only one virus, we expect that further investigation will show that many small spherical viruses have cubic symmetry, for the reasons given below.

Now a virus possessing cubic symmetry must necessarily be built up by the regular aggregation of smaller asymmetrical building bricks, and this can be done only in a very limited number of ways. Since viruses are made of protein and ribonucleic acid, both of which contain asymmetric carbon atoms of one particular hand only, those symmetry elements (mirror planes and centres of symmetry) which turn a right hand into a left hand are *impossible*. Thus we can only have rotation axes, and for cubic symmetry this limits us to only three different combinations of symmetry elements.

Table 1. THE THREE POSSIBLE CUBIC POINT GROUPS FOR A SPHERICAL VIRUS

Crystallographic description	No. and type of rotation axes present	No. of asymmetric units	Platonic solid with these symmetry elements
23	3 2-fold 4 3-fold	12	Tetrahedron
432	6 2-fold 4 3-fold 3 4-fold	24	Cube Octahedron
532	15 2-fold 10 3-fold 6 5-fold	60	Dodecahedron Icosahedron

The number of sub-units will be the same as, or a multiple of, the number of asymmetric units

Each of these three classes must contain at least four three-fold axes and three two-fold axes, arranged as for a tetrahedron. The first class contains no additional type of axis, while the second and third have four- and five-fold axes, respectively. Such an arrangement of symmetry elements is known as a 'point group', in contrast to a space group which applies to a regular arrangement extending to infinity. In Table 1 are listed the three cubic point groups possible for virus particles and also the regular polyhedra which have these symmetry elements (among others). Notice that in all these point groups the minimum number of asymmetric units must be a multiple of 12.

Three further points must be made to prevent misunderstanding. First, it is possible to arrange sub-units in other ways to produce a spherical shell, but the symmetry will not be cubic, and as they are less likely we shall not discuss them further here. Second, the asymmetric unit, upon which the symmetry elements act to build up the spherical shell, may consist of several identical sub-units joined together in some unsymmetrical fashion. This occurs quite often in protein crystals and would not be unexpected. Nor need the sub-unit be a single protein molecule in the chemist's sense of a unit joined together by chemical bonds. Several different protein molecules may aggregate to form the asymmetric unit. Third, our predictions concern the symmetry elements present in a virus particle, not its exact shape. However, this is likely to be approximately spherical, and may, under high resolution, appear polyhedral or perhaps with bumps on, like a rather symmetrical mulberry. Both these forms have been seen in electron micrographs.

It is not easy to explain in a short space why there are so few ways of building a spherical shell, but the reader can soon convince himself that it is difficult by trying to draw identical shapes which completely cover the surface of a tennis ball. It is impossible, for example, to do this entirely with hexagons, even if their shape is irregular. The point is very well stated in D'Arcy Thompson's "On Growth and Form"[17], in which we find "the broad, general principle that we cannot group as we please any number and sort of polygons into a polyhedron, but that the number and kind of facets in the latter is strictly limited to a narrow range of possibilities". The reason is essentially a topological one.

From the present X-ray evidence we are unable to distinguish the respective contributions of the protein and the ribonucleic acid, so we cannot be sure whether the cubic symmetry is perfect and applies strictly to both of them. We cannot tell whether the protein sub-units contain identical sequences of amino-acids, or whether the ribonucleic acid sub-units (if they exist) have identical sequences of nucleotides. It should not be very difficult, by end-group analysis, to decide whether the protein components are all approximately equal. By analogy with tobacco mosaic virus we would guess that this will be found to be the case. With the ribonucleic acid component, however, the problem is more difficult than it was in the case of tobacco mosaic virus, as the number of nucleotides per sub-unit is certainly much larger. (This follows from the higher percentage of ribonucleic acid[7] and the much smaller number of protein sub-units.) Only with a more detailed understanding of the ribonucleic acid core is the problem likely to be settled.

Animal and Other Viruses

For animal viruses we are handicapped because there is no X-ray evidence available so far. However, it is now becoming clear[2] that many of the smaller animal viruses, such as poliomyelitis and the various encephalitic viruses, are morphologically very similar to the spherical plant viruses. Not only are they of similar size (approximately 300 A. diameter); but it has recently been shown[18] that poliomyelitis virus also contains ribonucleic acid and can form crystals which appear as regular as those produced by the plant viruses. We thus think it very probable that cubic symmetry also extends to these animal viruses, and that the soluble antigens[19] (of about 120 A. diameter) frequently observed in infected cells are related to the sub-units normally used in the assembly of the final infective virus.

We also see no reason why our hypothesis should not be valid for viruses containing deoxyribonucleic acid rather than ribonucleic acid. Although the structure of bacteriophages is usually more complex than the smaller viruses discussed here, the fact that their heads appear polyhedral suggests that ideas of this general type may apply to them, too. On the other hand, it is less likely that they will be relevant to the structure of the larger viruses like vaccinia.

Conclusion

We can now describe our hypothesis in a more general manner. We assume that the basic structural requirement for a small virus is the provision of a shell of protein to protect its highly specific packet of ribonucleic acid. This shell is necessarily rather large, and the virus, when in the cell, finds it easier to control the production of a large number of identical small protein molecules rather than that of one or two very large molecules to act as its shell. These small protein molecules then aggregate around the ribonucleic acid in a regular manner, which they can only do in a limited number of ways if they are to use the same packing arrangement repeatedly. Hence small viruses are either rods or spheres. The number of sub-units in a rod-shaped virus is probably unrestricted, but for a spherical virus the number is likely to be a multiple of 12. Every small virus will contain symmetry elements and in favourable cases these can be discovered experimentally.

We believe that this hypothesis is likely to apply (in this form or a simple variant of it) to all small viruses which have a fixed size and shape.

Structure of Bushy Stunt Virus

CRYSTALS of bushy stunt virus yield detailed X-ray diffraction patterns indicating a high degree of regularity in the virus structure. Bernal, Fankuchen and Riley[1] found that the unit cell is body-centred cubic with one virus particle per primitive lattice point. Previous X-ray photographs[1,2] did not show whether the symmetry as well as the shape of the lattice is cubic. This is of considerable interest, since cubic symmetry for the lattice would imply that the individual virus particles possess cubic symmetry[3]. This is discussed in the preceding article (by Crick, F. H. C., and Watson, J. D.).

Precession photographs have been obtained from single crystals of bushy stunt virus which were grown by Messrs. F. C. Bawden and N. W. Pirie and kindly supplied by Dr. C. H. Carlisle. Two of these photographs, showing the basal reciprocal lattice planes normal to the edge and body diagonal of the cubic unit cell, are illustrated in Figs. 1 and 2. These show two- and three-fold symmetry respectively about the cube edge and cube diagonal, and establish the space group as $I\,23$ ($a = 386$ A.).

Early in this study, photographs were obtained from a disordered crystal which did not give lattice reflexions but in which the relative orientation of the virus particles appears to have been maintained. In one particular orientation this crystal gave a pattern of diffuse reflexions lying in several rings, each of which contained ten symmetrically arranged spots. This suggests that the virus particle has five-fold as well as two- and three-fold symmetry.

If the virus has the point-group 532, rather than merely 23, it will have additional symmetry axes. There will be one set each of two-fold, three-fold and five-fold axes lying in non-crystallographic directions, as well as the set of two-fold and the set of three-fold axes belonging to the space group. The directions of members of each of these five sets are shown in Figs. 1 and 2, except for the three-fold axes of the space group which can be seen in another photograph not reproduced here.

The intensity distribution which such symmetry is likely to produce on an X-ray photograph is best considered by reference to the Fourier transform of an individual virus particle. It can be shown that this transform is likely to exhibit spikes of high intensity extending from the origin along the direction of the symmetry axes. The X-ray pictures actually confirm the existence of such spikes along the postulated axes. The only difficulty in the identification arises from the fact that the symmetry of the crystal lattice (23) is lower than that of the individual virus particles (532). This means that directions in the transform which are related by the symmetry of the virus particle have to be sampled on reciprocal lattice points which have no symmetry relation, and the arrangement of which tends to obscure or confuse the underlying symmetry of the transform. However, allowing for this sampling difficulty, it is found that the radial variation of intensity near one type of diad of the point groups 532 is very similar to that near the other type; this is exemplified especially by regions of zero intensity occurring at the same distance from the origin along both types of dyads. A similar correspondence is also found for the two types of triads. Moreover, the intensity variations along the dyads and triads are different.

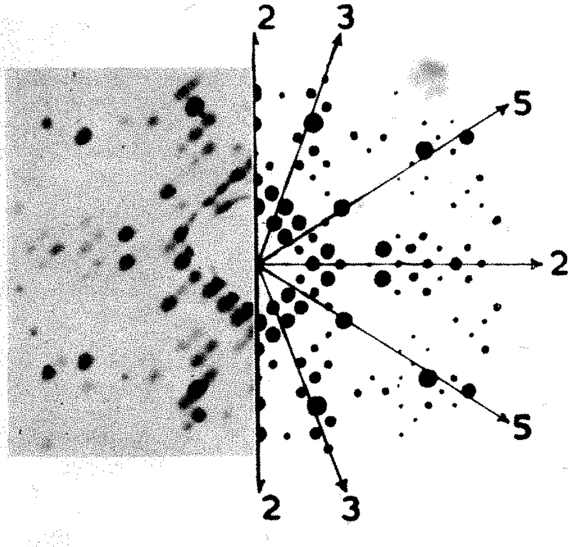

Fig. 1. Precession photograph of basal reciprocal lattice plane normal to the cube edge of bushy stunt virus crystal (left). Weighted reciprocal lattice net showing the orientation of the two-, three- and five-fold axes of the point group 532 which lie in this plane (right). The two-fold axes in this plane lie along the [100] directions of the lattice

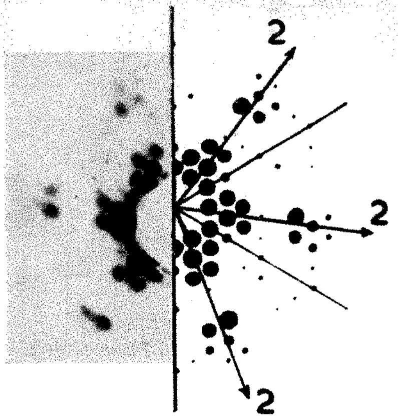

Fig. 2. Basal reciprocal lattice plane normal to cube diagonal showing the orientation of the two-fold axes of the point group 532 which lie in this plane. The unlabelled lines lie along the [110] directions of the lattice

All the evidence indicates that the virus has the point-group symmetry 532, which implies that it is built up of sixty structurally identical asymmetric units. The molecular weight of bushy stunt virus is about 9 million[4], of which about 17 per cent is ribonucleic acid[5]; therefore, the molecular weight of the protein part of the asymmetric unit is about 125,000. The point group symmetry does not preclude the possibility of each crystallographic unit being subdivided further into a number of chemically identical protein molecules. Thus 125,000 is a maximum value for the size of the protein sub-unit.

Chemical evidence, in fact, does suggest that the protein sub-unit may perhaps be smaller than this. There have been no end-group analyses reported for bushy stunt virus, but its amino-acid analysis obtained by de Fremery and Knight[5] can be used to calculate the minimum size of the sub-unit. Tryptophan, cysteine, methionine and histidine are present in very small amounts and approximately in the molar ratio 1 : 2 : 2 : 3. Assuming that all the protein molecules in the virus are identical (which may not be true) these analyses give a minimum molecular weight of 25,000–28,000, suggesting perhaps three hundred protein sub-units.

Thus the X-ray evidence shows that bushy stunt virus possesses sub-units. The number of sub-units is certainly a multiple of twelve and very probably a multiple of sixty. The chemical data suggest that the actual number may be as high as three hundred.

I gratefully acknowledge the advice and assistance of Drs. J. D. Watson and F. H. C. Crick.

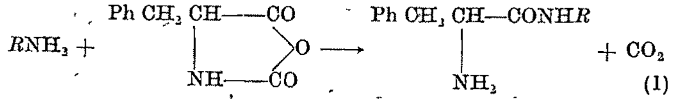
The 'Chain Effect': a Possible Analogue of Enzyme Action

We wish to report a novel type of reaction in which the polymerization of DL-phenylalanine N-carbonic anhydride is initiated by polysarcosine (as dimethylamide). This reaction, which has brought to light some features that are potentially of general importance in reactions involving polymers, shows marked analogies with processes in which enzymes function as catalysts.

The normal propagation reaction in the polymerization of DL-phenylalanine N-carbonic anhydride initiated by primary or secondary bases is:



$$RNH_2 + \underset{NH\text{——}CO}{\overset{Ph\,CH_2\,CH\text{——}CO}{|\qquad\quad >O}} \longrightarrow \underset{NH_2}{\overset{Ph\,CH_2\,CH\text{—}CONHR}{|}} + CO_2 \qquad (1)$$

and when carried out in nitrobenzene solution at 15°, it has[1] a bimolecular rate constant of 0·6 mole^{-1} l. min.$^{-1}$. However, if polysarcosine with a degree of polymerization (n) of about 20 is used as initiator, the ensuing reaction may be several hundred times as fast as would be expected on the basis of this rate constant. The initial rate of reaction, measured for a given polysarcosine concentration, is a function of n as shown in Fig. 1. The rate of the normal propagation reaction obtained with non-polymeric initiation for the same concentrations of anhydride and base is only 3×10^{-4} mole l.$^{-1}$ min.$^{-1}$ and is indistinguishable from zero in the graph. It is evident that the polysarcosine chain is capable of exercising a remarkable catalysis upon the reaction, and we designate this the 'chain effect'.

When low concentrations of polysarcosine are employed, the rate of reaction, initially high, may fall to the value corresponding to the normal propagation reaction after a comparatively small degree of conversion, and unchanged anhydride remains in solution. Titration of the reaction mixture shows that the base groups are still free at this stage, no acid formation being detectable in the system. It seemed likely that the reaction product—poly-DL-phenylalanine—was an inhibitor, and this has been confirmed by experiments in which this polymer was added initially. Under these conditions no rapid reaction was observed.

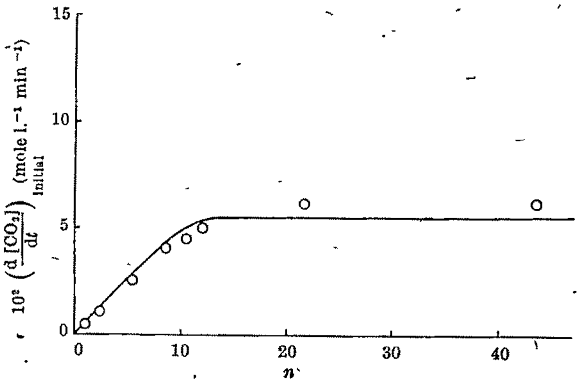


Fig. 1. Dependence of initial rate on length of polysarcosine chain. Reaction in nitrobenzene at 15° C. $[M]_0 = 0{\cdot}1$ mole l.$^{-1}$, concentration of polysarcosine dimethylamide $= 0{\cdot}54 \times 10^{-2}$ mole l.$^{-1}$. ○, Experimental points; full curve calculated on the basis of equations 2(a), (b)

In order to observe the chain effect in the system described, it is necessary for the polysarcosine chain to carry a terminal base group. If this is acetylated, no reaction occurs. Addition of a primary or secondary base (for example, piperidine) to the solution containing anhydride and acetylated polymer leads to a reaction which has only about a tenth of the rate of that due to the chain effect, indicating that the base is much more effective when attached to the polysarcosine chain.

We believe that the chain effect arises as a result of attachment of the anhydride molecules to the polysarcosine chain, probably by hydrogen bonding between the >NH groups of the former and the >CO groups of the polymer. Polysarcosine would be expected to be particularly effective in this respect, since it contains no >NH groups, and is therefore unable to form inter-peptide hydrogen bonds. On the other hand, poly-DL-phenylalanine, which contains >NH groups, does not give rise to the chain effect. As a result of the 'adsorption' of the anhydride by the polysarcosine, the concentration of anhydride in the proximity of the base is greatly increased, and since the polysarcosine chain is fairly flexible, the collision frequency between the base and the anhydride is much higher than that calculated on the basis of the overall concentrations of the reactants. Calculations of the order of magnitude suggest that this mechanism is sufficient to account for the high rate observed, even if it is assumed that the reactivity of the anhydride is not increased by adsorption. The chemical changes occurring are probably essentially similar to those in (1), and the final product is a block copolymer of sarcosine and poly-DL-phenylalanine. The process described would not operate when unattached base and acetylated polysarcosine are used, but hydrogen bonding between base and polymer may be sufficient to give a small degree of attachment.

The inhibition of the reaction by poly-DL-phenylalanine is readily understandable on this mechanism, since this polymer would form interchain hydrogen bonds with the polysarcosine, leading to aggregates of chains in which the accessibility of the adsorbed anhydride to the base is low, for steric reasons. Further, it would be expected that the nature of the solvent would be an important factor. This is so in practice; the chain effect in NN-dimethylformamide solution is only small. This liquid is capable of hydrogen bonding to the anhydride and the polymer, and this will reduce the adsorption of the anhydride by the polymer. N-substituted carbonic anhydrides should not show the chain effect unless the substituent carries a strong hydrogen-bonding group.

The observed dependence of the initial rates of reaction upon the experimental variables (n, anhydride concentration $[M]$ and sarcosine residue concentration $[S]$) is accounted for by the following simple kinetic scheme:

$$\begin{array}{lll} S + M \rightleftharpoons E & (a) & \\ E \rightarrow \text{products} & (b) & \end{array} \qquad (2)$$

where E represents an adsorbed DL-phenylalanine N-carbonic anhydride molecule. The equilibrium in

2(*a*) is supposed to be maintained throughout the reaction; the rate-determining step 2(*b*) requires the intervention of the base group at the end of the chain upon which *E* is situated, but this does not, of course, appear in the kinetic equations. The products in 2(*b*) are carbon dioxide and a phenylalanine residue which becomes joined to the terminal base group. The kinetic behaviour is quite different from that observed with the normal propagation reaction.

The process giving rise to the chain effect may therefore be visualized as the growth of one polymer on the surface of another in solution. It has analogies with heterogeneous reactions at interfaces. Of greater interest is the possible analogy with enzymic reactions. The dependence of the rate of the polymerization reaction upon the experimental variables, which is usually of the form shown in Fig. 1, resembles that found with enzymic reactions, and indeed the scheme (2) is similar to the simple Michaelis–Menten mechanism. The importance of the resemblances between the two types of system should become clearer with further work with other polymers and reactants.

Carbohydrases in Blow-fly Larvæ

Hobson[1] showed that glycerol and/or dried preparations of the gut and salivary glands of *Lucilia sericata* Meig. showed strong proteinase activity but very little carbohydrase activity, only starch being hydrolysed, whereas maltose, sucrose and lactose were not hydrolysed at all. Since that report, these results have been quoted[2] to support the plausible example of adaptation, wherein larval and adult blow-flies are assumed to possess digestive ability corresponding to their diet. Thus larvæ feeding on a protein-rich diet are adequately provided for because the gut shows strong proteolytic activity and the lack of carbohydrases is of no consequence. The reverse picture is presented in adult blow-flies which feed principally on carbohydrates; very active carbohydrases are present but only relatively weak proteinases.

However, Evans[3] has recently established that gut tissues from the larvæ of *Calliphora erythrocephala* Meig. are able to hydrolyse a wide range of carbohydrates, there being little difference in this respect between larvæ and adults. Using the same techniques, it has now been demonstrated that *Lucilia sericata* larvæ are also capable of hydrolysing a wide range of carbohydrates. The salivary glands or gut tissues were incubated on a welled microscope slide in buffered substrate (*p*H 6·8) which had previously been saturated with toluene. Hydrolysis of non-reducing substrates was readily detected by placing the slides on a hot plate after the addition of Benedict's sugar reagent and noting the appearance of red cuprous oxide. Any change in sugar content of reaction mixtures with reducing substrates was determined by paper chromatographic analyses of samples of the reaction mixture before and after incubation. In all experiments suitable controls using denatured tissues were always employed.

The following substrates were hydrolysed by salivary gland and mid-gut tissue from *Lucilia* larvæ: maltose, sucrose, trehalose, α-methyl galactoside, raffinose, melezitose, starch; whereas the following were not hydrolysed: α-methyl glucoside, lactose, melibiose, cellobiose, cellulose.

These results, which are similar to those obtained for *Calliphora*, are of interest in relation to the problems of carbohydrase specificity. Fraenkel[4] explained the ability of adult *Calliphora* to digest a range of carbohydrates by assuming the bond-specificity concept of Weidenhagen[5]. So far as the disaccharides and trisaccharides were concerned, only enzymes capable of splitting α-glucoside and α-galactoside linkages were required to be present. However, the carbohydrase activity of larval blow-fly tissues cannot be accounted for so easily because: (1) α-methyl glucoside is not hydrolysed, unlike all the other sugars containing an α-glucoside bond, namely, maltose, sucrose, trehalose and melezitose; (2) α-methyl galactoside is hydrolysed, but melibiose, another α-galactoside, is not. It is clear that the properties of larval blow-fly carbohydrases do not completely exemplify Weidenhagen's hypothesis of bond specificity, the over-generalized nature of which has been criticized more recently[6]. Much more information about the properties of animal carbohydrases is necessary to give a satisfactory explanation of the ability to digest certain carbohydrates and not others in terms of bond specificity or otherwise.

Comparative Antiœstrogenic Potencies of Progesterone and 17α-Hydroxyprogesterone

Progesterone is known to be not only a progestational compound but also to exert various antiœstrogenic actions: it prevents œstrogen-induced abdominal fibroids, œstrogen-induced growth of the myometrium, and œstrogen-induced excessive luteinization[1]. The antiœstrogenic potency of progesterone is diminished by oxidation at C_{21}, C_{11} and C_{17} [2,3]. The validity of this rule has been demonstrated by comparing progesterone with C_{11}-derivatives such as 11β-hydroxyprogesterone and 11-keto-progesterone, and with a C_{21}-derivative such as deoxycorticosterone. As to oxidation at C_{17}, comparison was made between deoxycorticosterone and Reichstein's compound *S* or 17α-OH-11-deoxycorticosterone[2]. Thus the conclusion as to loss of antiœstrogenic potencies due to oxidation at C_{17} in the α-position has been so far an indirect one; a comparison of progesterone with 17α-hydroxyprogesterone was still lacking. Results with the latter are given in the present communication.

Table 1. TWENTY-TWO CASTRATED FEMALE GUINEA PIGS RECEIVING ŒSTRADIOL AND 17α-HYDROXYPROGESTERONE OVER A PERIOD OF THREE MONTHS

No of animals	Œstradiol per day (μgm.)	17α-hydroxy-progesterone per day (μgm.)	Fibrous tumoral effect (ref 2)	Coeff. Q_{2-3} (ref. 2)	Uterine weight (gm.)	No. of pellets and concentration of 17α-hydroxyprogesterone
6	51	9 (8–10)	5·9 ± 1·1 (2–9·5)	1·5	4·[illegible] (2·3–6·5)	½; 40%
10	43	16 (13–19)	8·5 ± 0·4 (7–11)	2·9	5·7 (2·7–11·8)	½–1; 40%
6	44	136 (123–145)	7·5 ± 1·5 (2·5–12)	2·2	6·3 (5·2–13·0)	1; 100%

Pellets of 17α-hydroxyprogesterone were implanted beneath the skin of castrated guinea pigs; pellets of œstradiol also were implanted. Absorption was of 2·1 μgm. per sq.mm. of 17α-hydroxyprogesterone, against 3·3 μgm. of progesterone. Results for twenty-two animals receiving œstradiol and 17α-hydroxyprogesterone are given in Table 1; comparison between fifty-two animals receiving œstradiol and progesterone[4] is made in Fig. 1.

As seen from the table, neither œstrogen-induced abdominal fibroids nor uterine growth was prevented with as much as 136 μgm. of 17α-hydroxyprogesterone a day. On the other hand, as seen in Fig. 1, the fibrous tumoral reaction with 15 μgm. of progesterone per day was only 1·5 against 7·5 with amounts of 17α-hydroxyprogesterone eight or nine times greater than that. The coefficient Q_{2-3}, which refers to incidence of larger tumours only, was no less than 2 with 16 μgm. and even with as much as 136 μgm. of 17α-hydroxyprogesterone (Table 1); on the other hand, Q_{2-3} was zero with 15 μgm. of progesterone[4]. In Fig. 2 the maximal œstrogen-induced fibrous reaction in the presence of 13–24 μgm. of progesterone per day is compared with the non-maximal reaction in the presence of 123–145 μgm. of 17α-hydroxyprogesterone per day.

Uterine weight was 2·8 gm. and 5·7 gm. with 15 μgm. of progesterone and 17α-hydroxyprogesterone respectively (Fig. 1).

It is also of interest to compare results obtained with 17α-hydroxyprogesterone with those obtained with C_{11} and C_{21} derivatives of progesterone: as to antifibromatogenic and antihysterotrophic potencies, it is inferior to 11β-hydroxyprogesterone, to 11-ketoprogesterone and to deoxycorticosterone[2].

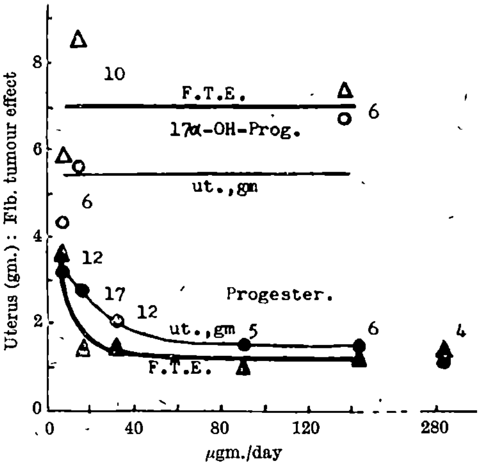

Fig. 1 Fibrous tumoral effect (△) and uterine weight (○) of twenty-two castrated females receiving œstradiol and 17α-hydroxyprogesterone, compared with 52 castrated female guinea pigs receiving œstradiol and progesterone (▲ and ●). Figures indicate number of animals in the group (Variations of fibrous reaction and uterine weight with 17α-hydroxyprogesterone are considerable; see also Table 1 But these differences between the 17α-hydroxyprogesterone groups are not significant and thus of no interest. The average in animals receiving only œstradiol may vary, according to the groups, between 4 and 7 or more)

Thus, there is full evidence that with oxidation at C_{17} the antiœstrogenic potencies of progesterone are diminished and in a manner seemingly more pronounced than with oxidations at C_{11} or C_{21}.

Comparative results as to antiœstrogenic potencies of progesterone and the oxy-derivatives mentioned are of considerable interest because the latter occur also in the body of mammals[5]. But results with 17α-hydroxyprogesterone deserve special attention in view also of recent findings with its caproate ester: whereas the free compound administered to women by intramuscular injection is without progestational action, the caproate ester is progestational[6]—apparently 're-acquired' through esterification. We have not yet examined whether antiœstrogenic potencies are also re-acquired by the caproate ester of 17α-hydroxyprogesterone.

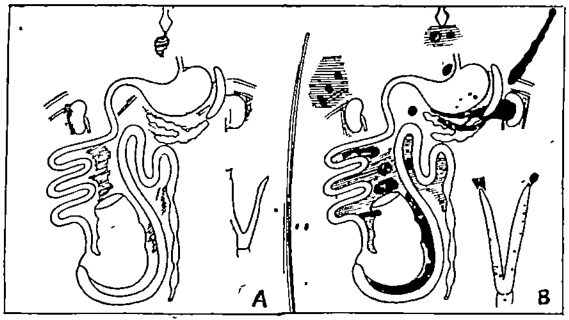

Fig. 2. Fibrous tumoral effect. Solid black surface, massive fibrous tumours; shaded areas, fibrous strands (A) Maximal fibrous reaction in a group of seventeen animals receiving during three months œstradiol and 13–24 μgm of progesterone per day Fibrous tumoral effect, 1·5. (B) Non-maximal fibrous reaction in a group of six animals receiving œstradiol and 123–136 μgm. of 17α-hydroxyprogesterone per day. Fibrous tumoral effect, 10

Thanks are due to Prof. Carl Djerassi, of Wayne University, for the sample of 17α-hydroxyprogesterone, and to Syntex, S.A., Mexico, for a generous supply of œstradiol.

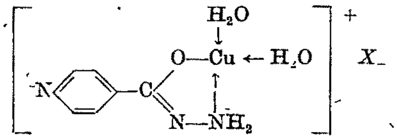
Mode of Action of *Iso*nicotinic Hydrazide

In our earlier report we directed attention to the importance of chelation as an essential step in the anti-tuberculous activity of *iso*nicotinic hydrazide (isoniazid)[1]. It was impossible to decide whether the chelating action with a metal or metals took place before (in the medium) or after adsorption on the bacterial cell.

Since then we have had the opportunity of examining the activity *in vitro* and *in vivo* of the relatively insoluble cupric complex of isoniazid :



X_- = a univalent anion

The results now reported (see Table 1) indicate that this complex is highly active. Thus, it might now be postulated that isoniazid is probably inactive in the absence of a chelating metal, and that its anti-tuberculous activity is, in fact, due to its metal complex, in this instance the cupric derivative. These findings are strongly reminiscent of those obtained in earlier studies of the mode of action of 8-hydroxyquinoline (oxine)[2].

Table 1. ACTIVITY OF *iso*NICOTINIC HYDRAZIDE AND ITS CUPRIC CHELATE COMPLEX

Compound	Anti-tuberculous activity		
	In vitro (ref. 5) Tuberculostatic end-point. Medium : synthetic serum-synthetic		*In vivo* (ref. 3) Healing ulcer response
*Iso*nicotinic hydrazide (isoniazid)	2,048,000 (0·07 μgm /ml.)	2,048,000 (0 07 μgm /ml.)	20 mgm /kgm. weekly I.M. *HR* 100 in 28 days.
Cupric complex of isoniazid	4,096,000 (0·08 μgm./ml.)	512,000 (0 6 μgm./ml)	20 mgm./kgm. weekly I.M *HR* 99 in 28 days.

It will be noted that the activity *in vivo*, examined by the healing-ulcer technique previously reported[3]; is extremely high, two injections effecting 85 per cent cure (*HR* value 85) in three weeks and 99 per cent cure in 28 days after three injections.

This copper derivative appears to be as active as isoniazid, verazide[4] or any drug we have tested so far. However, it exhibits a profound local and general toxicity in mice and guinea pigs. During treatment of guinea pigs by intramuscular injection, a severe gangrenous necrosis and ulceration developed at the site of injection, and in mice the acute toxicity (*LD*50) was as low as 36 mgm./kgm. body-weight compared with 200 mgm./kgm. for isoniazid itself.

The interest in these findings centres on the demonstration that the copper-isoniazid chelate complex is active *in vitro* and *in vivo* under conditions in which it is unlikely to break down to isoniazid. This observation, taken in conjunction with our earlier findings[1], has led us to conclude that the anti-tuberculous activity of isoniazid is expressed after it has formed a chelate metal complex in the medium or the animal body in which it is acting. The identity of the complexing metal *in vitro* or *in vivo* is still unknown, and the activity of other metal complexes is being investigated.

We thank the National Health and Medical Research Council of Australia and the Rockefeller Foundation for partial financial support.

Reduction to Normal Levels of the High Erythrocyte Sedimentation-Rates in Apparently Healthy South African Bantu Men

In the tropics and semitropics, unusually high values for erythrocyte sedimentation-rates are common among apparently healthy individuals. Thus, among seventy-five medically fit young Indian medical students, the mean rate (Wintrobe's method)[1] was 11·2 ± 9·4, range 0·5–30 mm. ; high values are assumed to be pathological, although the cause was unknown[2].

Neither malnutrition nor under-nutrition (unless very severe) is believed directly to influence erythrocyte sedimentation-rate[3]. Nevertheless, we find that although very high rates are common among different regional groups of apparently healthy Bantu mine-workers, the mean high values become reduced to within normal limits after subjects, without any medical treatment, have consumed for four–fifteen months the excellent diet provided in the mine compounds.

The Bantu mine-workers were eighteen to forty years old, in good physical condition, not anæmic, and free from radiological tuberculosis. No significant enlargement of liver, spleen or lymph nodes was apparent. Subjects were variously parasitized, particularly the tropical group. The Kolmer–Wassermann test for syphilis was positive in 4 per cent of cases. The majority showed liver dysfunction as revealed by the common biochemical tests on serum.

Workers came from areas where the diet is usually adequate in calories and gross protein, but is low in animal protein, fat and certain mineral salts and vitamins. The mine compound diet, which may be eaten to satiety, is nutritionally adequate.

The erythrocyte sedimentation-rate was determined on oxalated blood using Wintrobe's method[1], two technicians working in parallel, and determinations being completed within 3 hr.

In Table 1, only in the mixed group do data refer to the same individuals examined at the beginning and end of periods of service.

Our results revealed an equal degree of abnormality of erythrocyte sedimentation-rate among recruits with and without previous periods of service in the mines : this finding suggests that the normal values found on leaving the mines rise again on returning for some months to conditions of tribal life.

The dramatic and unexpected changes in erythrocyte sedimentation-rate found in these outwardly healthy subjects are not due to any medical treat-

Table 1. SEDIMENTATION-RATES IN BANTU MINE-WORKERS AT THE BEGINNING AND END OF PERIODS OF SERVICE

Subjects	Mean erythrocyte sedimentation-rate, standard deviations, ranges, and (in brackets) number of subjects	
	Values at beginning of service	Values after 4–15 months period

ment, and we are driven to ascribe the changes directly, or indirectly, to the consumption of an excellent diet for several months. The precise explanation and significance of our observations remain to be established; nevertheless, it is suggested that in future studies on the nutritional status of non-white populations, determinations of erythrocyte sedimentation-rate may contribute valuable information.

We are grateful to Dr. R. C. Pearson and the late Dr. R. M. Yeo, of the Witwatersrand Native Labour Association Hospital, who facilitated the collection of blood from some of the groups of Bantu mine-workers, and to Miss G. McNab, of this Institute, for carrying out the Kolmer–Wassermann tests. This communication is published with the permission of the South African Council for Scientific and Industrial Research.

Effect of a Coliform Organism (*Escherichia*) on the Second Ecdysis of Nematode Larvæ parasitic in the Horse

IT was recently shown that third-stage infective larvæ of the family Strongylidae commonly parasitic in the horse would readily shed their protective sheaths in equine duodenal contents[1]. Similar results have also been obtained by Sommerville[2] using ovine material.

The effect of artificial duodenal contents prepared according to the formula given by Silverman[3] has recently been observed using infective equine nematode larvæ. Results using the fresh solution proved disappointing. In three separate experiments the average percentage ecdysis only reached 13·6 after five hours.

It was noted that artificial duodenal contents, kept in a laboratory where horses' fæces are regularly examined and where no special precautions were taken to preclude entry of bacteria, developed after five days an offensive odour reminiscent of equine duodenal contents. Larvæ of the same age as those used above were therefore placed in the contaminated solution and the degree of ecdysis observed. This reached 80 per cent after three hours and increased to 89 per cent after five hours. It seemed, therefore, that the contamination of the artificial duodenal contents had enhanced its power to induce ecdysis.

A coliform organism was afterwards isolated from the contaminated solution, and it was therefore thought that it might be profitable to assess the effect of bacteria of this type on the rate of ecdysis.

Accordingly, artificial duodenal contents were freshly prepared. The solution was passed through a Seitz filter, after which it was divided into two equal portions, one of which was inoculated with a known coliform organism (*Escherichia*) of equine origin. This was incubated at 37° C. overnight. Larvæ of the same age were placed in both solutions and the rates of ecdysis compared. Fig. 1 illustrates the results obtained. There can be no doubt that the presence of the coliform organism has accelerated the rate of ecdysis. At present, four coliform organisms

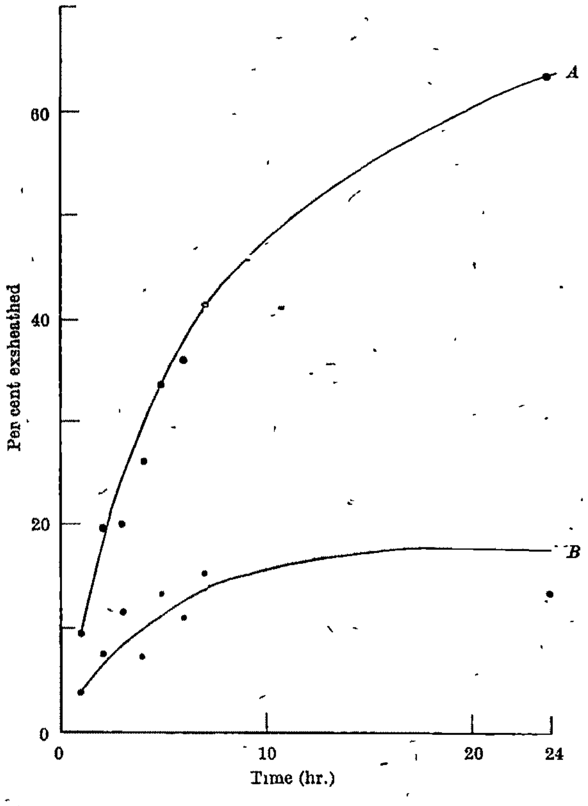

Fig. 1. The percentage of larvæ undergoing ecdysis plotted against the time in hours. Curve *A* shows the results in Seitz-filtered artificial duodenal contents plus coliform organisms (*Escherichia*). Curve *B* shows the results in Seitz-filtered artificial duodenal contents alone

(*Escherichia*) of different equine origin have been used and all have accelerated the rate of ecdysis.

Experiments have also been conducted using Seitz-filtered natural equine duodenal contents. Larvæ placed in this have never undergone great degrees of ecdysis, 9 per cent after twenty-four hours being the greatest yet recorded. In unfiltered duodenal contents, ecdysis regularly reaches 90–100 per cent before this time.

In all these experiments, mixed larvæ of the family Strongylidae were used. These were obtained from charcoal cultures of equine fæces, and it is likely that small amounts of bacteria were present on them, despite the fact that they were washed in sterile distilled water before use.

It is concluded that the presence of coliform organisms is necessary for the normal occurrence of the second ecdysis of nematode larvæ of the family Strongylidae commonly parasitizing the horse.

I wish to thank L. W. Mahaffey for advice on coliforms and supplies of pure cultures.

Adrenergic Sweating in Cattle

Cattle skin is abundantly supplied with sweat glands[1], and these glands have been suggested to be functional[2,3]; but very little is known about the secretory control. Muto[4] recorded that adrenaline produces marked sweating in horses and sheep but has no effect on the calf. Ferguson and Dowling[3], on the other hand, observed the formation of sweat droplets in the calf in response to intradermal injections of adrenaline. Precise information, however, on whether the control of sweat glands of cattle is adrenergic and/or cholinergic is still lacking. We have therefore extended our experimental work on the cutaneous evaporation in cattle, in order to test the response of sweat glands to some of the drugs affecting the sympathetic nervous system.

An American Brahman calf, between the ages of three and seven months, was exposed at intervals to an air temperature of 108° F. dry-bulb and 80° F. wet-bulb. Cutaneous evaporation was measured from the shoulder area using a semicircular capsule made of 'Perspex', with an area of 19·6 sq. cm. Hot-room air was circulated through this capsule at the rate of 2·5 lit./min. At frequent intervals, the hot air was passed, after it had circulated over the skin under the capsule, through an absorber (concentrated sulphuric acid), and at the same time the same quantity of air at the same rate of flow was passed through another identical absorber. The difference of gain in weight between the two absorbers represents the amount of water evaporated from the skin.

Results presented in Fig. 1 indicate that N-(2-chloroethyl) dibenzylamine hydrochloride (dibenamine) given intravenously at the rate of 7 mgm./kgm. body-weight gradually reduced sweating. Sweating was completely blocked three hours after the injection. During the course of adrenergic blockade intradermal injections of adrenaline and nor adrenaline (0·2 mgm.) given near the site of th capsule failed to stimulate sweating. On the followin day, the blockade of adrenaline action graduall diminished until the sweating-rate returned to it initial level; at this stage, injection of adrenalin increased the sweating whereas noradrenaline re mained ineffective. The action of dibenamine o cattle sweat glands is therefore similar to that o human sweat glands[5].

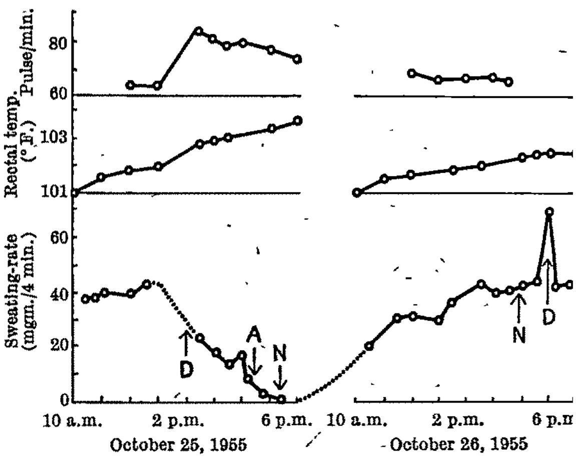

Fig. 1. Effect of dibenamine, adrenaline and noradrenaline on sweating-rate, rectal temperature and pulse-rate of a calf. Dotted lines indicate unmeasured intervals. Dibenamine (*D*), adrenaline (*A*) and noradrenaline (*N*) administered at points marked by arrows. Room temperature 108° F. dry bulb and 80° F. wet bulb

The inhibition of sweating induced by dibenamin was accompanied by increase in rectal temperature an pulse-rate with a room temperature of 108° F. As th sweating gradually increased on the following da the pulse-rate and the rectal temperature were foun to be below the levels recorded during administratio of dibenamine. Intramuscular injections of diben amine caused inhibition of sweating; but loca subcutaneous administration of 2 mgm. of 2-benzy 2-imidazoline (priscol), another adrenergic blockin agent, did not reduce sweating. A higher dosage c priscol (10 mgm.), on the other hand, caused profus sweating similar to that in man[6].

There was no response of sweat glands to sub cutaneous injections of atropine (60 mgm.) an acetylcholine (0·2 mgm.), but the injections c adrenaline given at the shoulder region increased th sweating-rate on the average from 32·1 to 45· mgm./cm.²/hr. Cattle sweat glands appear, therefor to be adrenergic, in this way differing from those c man, which are both adrenergic and cholinergic.

Thanks are due to Prof. W. V. Macfarlane for h assistance, advice and encouragement.

Transfer of Hydrogen from Alcohols to Quinones

WHEREAS an extensive study of hydrogen abstraction by methyl radicals in the gas phase has been reviewed[1], hydrogen transfer in solution has only recently been discussed and the various types classified[2] as an introduction to a general study of this phenomenon: in particular, some hydrogen transfers to quinones in solution have been studied[3]. It is therefore pertinent to indicate briefly the conclusions drawn from the determination of the reactivity of some simple alcohols to photo-oxidation sensitized by quinones.

Bolland and Cooper[4] have concluded from a variation of the quantum yields of reaction products with experimental conditions that alcohols are attacked by photo-excited anthraquinones A^* with the production of semiquinones $\cdot A$H as follows:

$$A^* + R\text{CH}_2\text{OH} \rightarrow \cdot A\text{H} + R\underset{\cdot}{\text{C}}\text{HOH} \qquad (a)$$

$$R\underset{\cdot}{\text{C}}\text{HOH} + \text{O}_2 \rightarrow R\text{CHOH} \atop {\quad\; | \atop \quad\; \underset{\cdot}{\text{O}_2}} \qquad (b)$$

the subsequent reactions of the hydroxyperoxy radicals leading to the formation of stable products.

It has been found from a kinetic study of the reaction using sodium anthraquinone-2-sulphonate in aqueous solutions that the reactivity of the alcohols to hydrogen transfer can be determined from measurements of the rate of oxygen uptake of the system under varying conditions. The following are reactivities determined for some simple alcohols:

Substrate	Reactivity per $>$COH group relative to ethanol
Methanol	~ 0·12
Ethanol	1·00
n-Propanol	1·53
n-Butanol	2·07
*Iso*propanol	2·14
tert. Butanol	~ 0·01
Ethylene glycol	0·289
1,2-Propylene glycol	0·625
2,3-Butylene glycol	1·49
Glycerol	0·280

Thus: (i) in the primary alcohols reactivity increases with increasing chain-length; (ii) in the glycols, reactivity increases with increasing methylation of the carbon atoms in the α-position to the hydroxyl groups; (iii) reactivity increases in the monohydric alcohols with increasing alkylation on the α-carbon atom until all hydrogen atoms are replaced, when a great reduction in reactivity results, that is, reactivity increases along the series t-BuOH $\ll$ MeOH $<$ EtOH $<$ *iso*PrOH; (iv) increasing hydroxylation of propanol produces a decreasing reactivity, that is, reactivity decreases along the series *n*-PrOH $>$ propylene glycol $>$ glycerol.

The increase in reactivity with increase in alkylation is in accord with trends of reactivity observed in cases of hydrogen transfer from the α-carbon atom of primary and secondary alcohols to other acceptors both in the vapour and liquid phases[1,5]. Observation (iv) would suggest that hydration has a hindering effect on the hydrogen transfer process. The above results were determined in neutral solution. However, using *iso*propanol, the reactivity to photo-excited sensitizer has been found to decrease with increasing acidity; this has been adequately interpreted in terms of formation of an oxonium ion $R_2\text{CH}\,\overset{+}{\text{O}}\text{H}_2$, which is unreactive compared with the alcohol itself. On this assumption a detailed analysis of the kinetics gives the value of

$$K_b = \frac{[(\text{CH}_3)_2\,\text{CH}\,\overset{+}{\text{O}}\,\text{H}_2]}{[(\text{CH}_3)_2\,\text{CHOH}]\,[\text{H}^+]}$$

for

$$(\text{CH}_3)_2\,\text{CHOH} + \text{H}^+ \overset{K_b}{\rightleftharpoons} (\text{CH}_3)_2\,\text{CH}\,\overset{+}{\text{O}}\text{H}_2$$

as 2·5 litres mole^{-1} at 0° C.

For the thermal hydrogen transfers between hydroaromatic compounds and quinones, which are accelerated by acid conditions, Braude *et al.*[3] have suggested a slow transfer of a hydrogen anion to the quinone followed by a rapid transfer of a proton. The heterolytic fission of the α C—H bond in the alcohols is unlikely to occur in these photochemical transfers as it would produce the ion $R_2\overset{+}{\text{C}}\text{OH}$, which could not yield by interaction with oxygen the $R\text{O}_2\cdot$ radical, a necessary intermediate in the formation of the stable products. Straightforward hydrogen atom transfer[6], and electron transfer[7] (in this case from the oxygen of the alcohol; Kenner, private communication) followed by proton expulsion, have been proposed as mechanisms for photo-oxidations sensitized by dyestuffs. For the alcohols:

hydrogen atom transfer:

$$A^* + R\text{CH}_2\text{OH} \longrightarrow \cdot A\text{H} + R\underset{\cdot}{\text{C}}\text{HOH} \qquad (a)$$

electron transfer:

$$A^* + R\text{CH}_2\text{OH} \xrightarrow{\text{slow}} \cdot A^- + R\text{CH}_2\overset{+}{\text{O}}\text{H} \qquad (c)$$

$$R\text{CH}_2\overset{+}{\text{O}}\text{H} \xrightarrow{\text{fast}} R\underset{\cdot}{\text{C}}\text{HOH} + \text{H}^+ \qquad (d)$$

The increase in reactivity with increase in alkylation on the α-carbon atom of the alcohols discussed above could be consistent with either hydrogen atom transfer or electron transfer, with the increasing inductive effect assisting the removal of the hydrogen atom or the electron. However, on the electron-transfer mechanism the rate-determining process (*c*) would be expected to be more facile with *tert.* butanol than with *iso*propanol. A detailed consideration of the mechanism shows that any difference in the subsequent behaviour of the radical of *tert.* butanol from those of the primary and secondary alcohols would change the rate of oxygen uptake, and hence the reactivity, by a factor of only two or three, since the rapid reversion of semi-quinone to quinone:

$$\cdot A\text{H}(\cdot A^-) + \text{O}_2 \rightarrow A + \text{HO}_2\cdot\,(\cdot\text{O}^-_2)$$

must still operate. Therefore, the very low relative reactivity of *tert.* butanol indicates that the reaction proceeds by simple hydrogen-atom transfer from the alcohol to the quinone, as in (*a*).

A detailed account of the kinetics and rate constants will be given elsewhere. This work forms part of the fundamental research programme of the Council of the British Rayon Research Association.

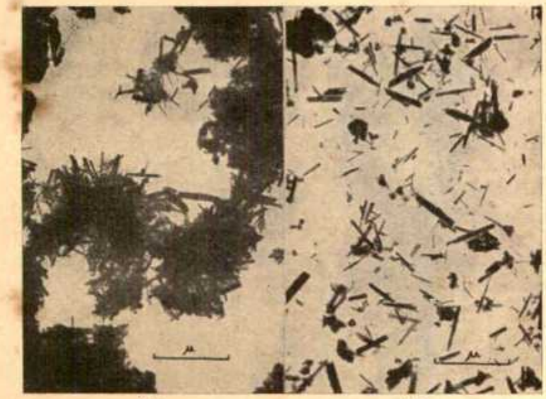
Petroleum Ether (80°-100° C.) used as a Dispersing Agent for the Examination of Particulate Matter by Electron Microscopy and Electron Diffraction

IN these laboratories, many powders of electrochemical interest have been produced and their structural properties examined by electron microscopy and electron diffraction, using a Metropolitan-Vickers *E.M.*3 instrument.

Deposits obtained from aqueous suspension methods utilized initially for specimen grid preparation frequently resulted in the aggregation of the fine particles present so that it was found necessary to employ a dispersion technique. Specimens made for transmission electron diffraction have always been degreased by spraying with a fine jet of petroleum ether. It was the use of petroleum ether in this connexion which led to the idea of determining its efficiency as a dispersing agent. For most of the substances which have so far been studied here, satisfactory dispersions of fine particles have been obtained by employing the following simple method.

A small quantity of the powder is placed on to a clean glass microscope slide. From a wash bottle constructed using 'Quickfit' ground-glass joints and having a fine jet, a few drops of petroleum ether are directed on to the powder. This is then crushed to a very fine paste by means of a lancet-pointed dissecting needle.

More dispersing agent is applied and the flat blade of the needle is moved across the slide, thus removing the larger particles and leaving a 'smear' of extremely fine particles. The 'smear' is moistened with a further small quantity of petroleum ether and the collodion film on a copper grid is drawn lightly over the dispersed material on the slide using a pair of forceps. After a few seconds (allowed for evaporation of any remaining liquid), the specimen grid is ready for insertion into the electron microscope.



(1) (2)

Fig. 1. Aqueous suspension deposit
Fig. 2. Petroleum ether dispersion

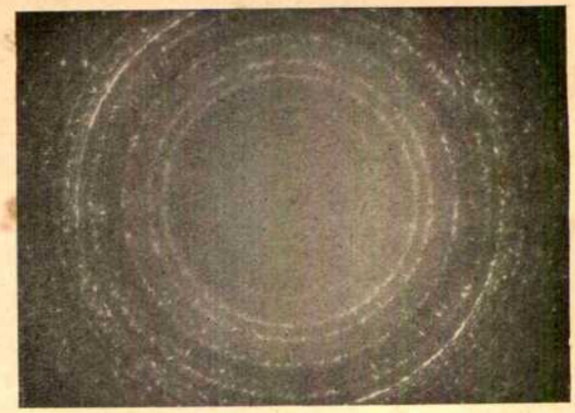


Fig. 3. Electron diffraction pattern from crystals similar to those shown in Fig. 2

The method has the following advantages: (*a*) It is suitable for the majority of inorganic and many organic materials which are insoluble in petroleum ether; (*b*) it is quick, as only one medium is used which rapidly evaporates; (*c*) the dispersed material is deposited on the membrane in such a way that it can be shadowed; (*d*) the dispersion is free from grease and is therefore suitable for electron diffraction.

Synthetic manganese oxides[1], oxides of lead, silver, nickel and vanadium, clay minerals, diatomaceous earth, pyranthrone and flavanthrone are some of the materials which have been investigated in this department by electron microscopy and electron diffraction after successful dispersion using the method described.

Figs. 1 and 2 show the rod-shaped crystals obtained from a sample of α-manganese dioxide (with potassium in the lattice) which had been heated at 400° C. in oxygen for 24 hr. The highly resolved transmission electron diffraction pattern of Fig. 3 was taken from crystals like those in Fig. 2.

Determination of Arc Temperatures using Shock Waves

SOME years ago, Suits[1] suggested and developed a method for the determination of the gas temperature of an arc discharge by the measurement of the velocity of a sound wave passing through the arc channel. The sound wave was obtained from the initiation of a spark discharge, and its propagation was observed by the increased brightness it produced in the channel. In his investigation, Suits observed that the original pressure disturbance created by the spark possessed abnormally high velocities which were rapidly attenuated with the propagation of the disturbance. However, since his experiments showed that for different spark-strengths, and hence for

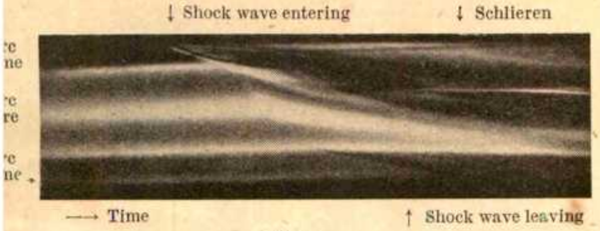

Fig. 1

different abnormal velocities, the same velocity was always obtained when the disturbance had reached the arc, he assumed that the disturbance had become attenuated to one possessing the normal sound velocity.

It is now well known[2] that these abnormal velocities are characteristic of a shock wave which is produced by spark initiation. It would appear, however, that the attenuation allowed by Suits was insufficient to produce a sound wave since (*a*) with a sound wave no arc brightening is to be expected, and (*b*) the records given by Suits show a bodily movement of the arc channel which is most likely due to the mass flow associated with the tail of a shock wave. We suggest, therefore, that Suits observed the passage of a shock wave; and calculations applied to his records indicate that his temperature values are about 5 per cent high due to the application of sound-wave calculation to the relatively weak shocks actually used. The use of strong shock waves would increase the error appreciably. It is also of interest to note that in allowing the shock wave to become attenuated, the sharpness of the pressure front is also reduced, thus producing a brightness change which is difficult to measure accurately. This may explain the relatively few measurable records obtained by Suits.

In the technique which we have developed, the shock wave produced by the spark is not allowed to become attenuated but is, on the contrary, maintained at maximum strength by enclosing the spark in a shock tube. In this way we obtain records showing a large brightness change and which are therefore accurately measurable. It is clear, however, that in these circumstances shock wave theory must be used if large errors are to be avoided. It was found that the application of the Rankine–Hugoniot equations to the arc, considered as a gas of uniform temperature bounded by two simple contact discontinuities, was insufficiently accurate owing to the appreciable radial temperature gradients which exist in the arc. We have therefore developed a theory which gives the variation of velocity of a plane shock wave with a continuously varying temperature distribution. It is then possible to determine the gas temperature at a point *A* if the shock velocity is known at *A* and if the velocity and temperature are known at some other point *B*. In order to obtain these data a schlieren system has been combined with a rotating mirror camera so that the shock propagation can be recorded in the regions outside the arc as well as in the arc channel. The local temperatures outside the arc are easily measured. A typical record is shown in Fig. 1. With this technique we have determined the following arc gas temperatures to an estimated accuracy of ± 150° K., after allowing for shock attenuation. (1) 40-amp. arc in air at 1 atm., cored carbon electrodes with 8-mm. gap, anode above, temperature in middle of gap 6,800° K. (2) 10-amp. arc in nitrogen at 2 atm., tungsten electrodes with 6-mm. gap, cathode above, temperature in middle of gap 6,650° K.

The method is complicated by the shock wave attenuation which occurs in the arc regions; but experiments have now shown that this difficulty may be minimized by using a pulsed arc inside the shock tube. The technique is being further developed in order to determine the decay of gas temperature subsequent upon arc interruption. It will be appreciated that by using a schlieren system the method is applicable to other determinations of non-luminous high gas temperatures.

Crystallite Orientation in the Tooth Dentine of *Macropus*

Mammalian dentine consists mainly of hydroxyapatite crystallites with an average size of about 0·03μ [1], and collagen fibres. If the latter are removed from a dentine section and the preparation embedded in a medium with a refractive index high enough to eliminate 'form' birefringence, the optical properties of the mineral are then seen, and it has been shown that the crystallites are orientated in definite patterns[2]. They may lie with their optic axes parallel with the original direction of the collagen fibres, parallel with the dentine tubules, or they may be 'spheritically' orientated.

In longitudinal sections of *Macropus* dentine, crystallites tend to lie parallel with the original collagen direction. However, in the root near the pulp cavity an unusual effect has been noticed, for when viewed between the crossed nicols of a polarizing microscope, such areas show well-defined black lines running across the dentine tubules (Fig. 1). The birefringent crystallites are arranged approximately at right angles to these lines, which are not artefacts produced by the embedding medium and which were initially thought to be zones either containing a different, isotropic mineral, or else possessing a low degree of calcification. It was later found that these lines may still be seen when a section is examined in plane-polarized light, but they are extremely faint and only visible when at right angles to the polarizer; rotating the section causes them to appear and disappear alternately.

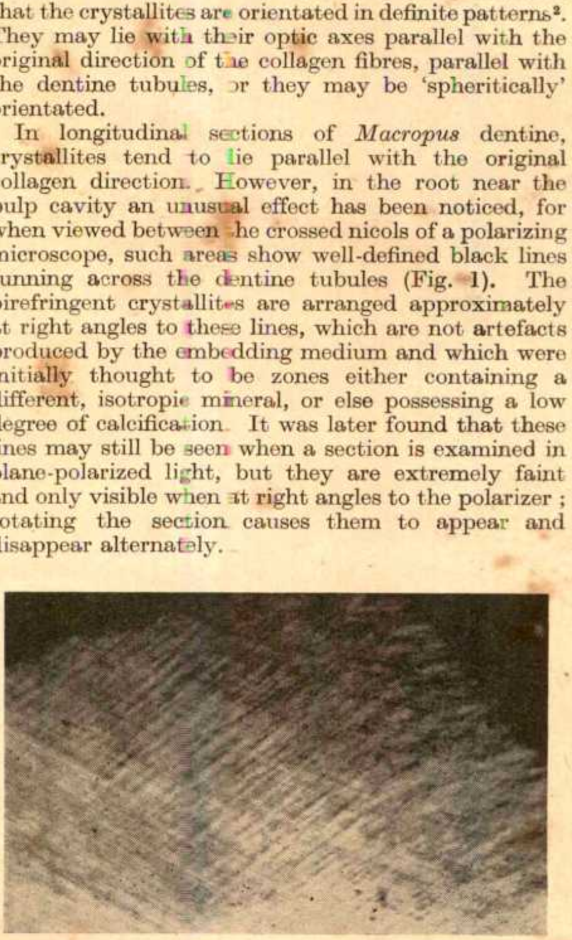

Fig. 1. Appearance of extracted *Macropus* dentine between crossed nicols

The explanation of this phenomenon now appears to be that all the mineral in the dentine is the same, but a somewhat regular, double orientation of crystallites exists. The majority of the crystallites lie in the plane of the section and therefore exhibit two refractive indices (n_e and n_0). These are broken up into groups by lines of similar crystallites the optic axes of which are perpendicular to the plane of the section and, therefore, show only one refractive index (n_0) and have no activity between crossed nicols. If the optic axes of the crystallites in the plane of the section are parallel with the vibration direction of the polarizer, the plane-polarized light is subject to the extraordinary refractive index (n_e), and the lines, which are at right angles to this vibration direction, will appear since the index of their mineral is somewhat different (n_0). On rotating the section through 90° all the crystallites will be showing the same index (n_0) and the lines become invisible.

Thanks are due to the Zoological Society of London for the material. It is hoped that a complete account of the structure of marsupial teeth will soon be available.

Slip during Fatigue of an Age-hardened Alloy

IT has long been suspected that the room-temperature fatigue properties of age-hardened aluminium alloys are dependent upon any over-ageing that may occur during a fatigue test[1]. This has recently been directly verified by comparison of fatigue behaviour at room and liquid-air temperatures[2]. It is supposed that alternating stresses cause dislocation movements which in turn generate vacant lattice sites. At room temperature these are mobile and can give rise to over-ageing by reason of the increase in the local diffusion-rate. At liquid-air temperatures this cannot occur, and the fatigue properties are much superior.

However, practically nothing is known about slip processes in age-hardened alloys. No slip bands are seen when single crystals are extended, and the stress-strain curves show little dependence upon orientation[3]. Nevertheless, examination of an aluminium alloy containing 6·6 per cent zinc, 3·0 per cent magnesium and 1·4 per cent copper and aged to peak ultimate tensile stress of 38·2 tons/sq. in., has revealed slip bands in specimens fractured in fatigue at room-temperature. Those shown in Fig. 1 were produced by etching a polished longitudinal section of a specimen which had broken after 10^5 cycles of ± 19·1 tons/sq. in. The crack is parallel to one set of bands and changes direction at a grain boundary (revealed by a different etch). It proved impossible to develop etch pits for the determination of crystal orientation in the fully hardened alloy; but after over-ageing specimens at 200° C. for a short time, satisfactory pits could be produced. At the same time, however, the bands disappeared and could not be re-etched. This suggests that the original etching effect was due to solute atoms which had segregated to dislocations stuck in the slip band, and that at 200° C. some redistribution occurred. The development by alternating strains of a yield point in this type of alloy has been noted[4] and supports this suggestion.

The structure shown in Fig. 2 was produced by re-etching the surface of the specimen shown in Fig. 1 after over-ageing but without intermediate repolishing. It is apparent that while two sets of traces may possibly be ascribed to intersections of (111) planes with the surface, the third may not. In aluminium, slip on (111) planes is commonly found, but very occasionally slip on (100) and (110) planes occurs in polycrystalline specimens deformed in tension[5]. The third trace is consistent with either (100) or (110) planes. This has been found for numerous bands: in addition wavy slip is also seen, as shown in Fig. 3.

No bands were found in a specimen fatigued at iquid-air temperatures.

The existence of many potential slip bands in age-hardened alloys undergoing fatigue provides an additional explanation of the poor fatigue properties of some age-hardening alloys relative to their static strength properties. Besides the possibility of over-ageing, slip can more readily occur in any one crystal and be transmitted to its neighbours. The alloy described is simply a super-pure version of a common commercial alloy, and it is of interest that crystallographic cracking can be found in such an alloy, although its analysis is complicated by the presence of gross inhomogeneities and intermetallics (Fig. 4).

Apparent Velocity of Alpha-Particles in Cloud Chambers

Visual demonstration of α-tracks in cloud chambers, especially of the diffusion type, sometimes gives the impression that the tracks actually shoot out from the radioactive source in a fraction of a second (not unlike the smoke trail of a train moving in a distant landscape, though the time-scale is different). It is curious not to find this effect mentioned in the literature, though it must baffle those teachers that have to correct their pupils when they think it is the actual velocity of the particles they are observing.

We suggest the phenomenon is due to the finite diffusion-rate of vapour molecules to the droplets that are forming, their growth being slower at the end of the track because of the stronger competition due to the larger density of ionization. Assuming the known values of this density and assuming the track to be a cylindrical sink in the diffusion field, we find the right order of magnitude for the retardation at the end, the track being fully developed in somewhat less than a second near the end, and in about half that time in the central part.

On a similar basis rests the explanation of a related condensation phenomenon that may be observed with yet simpler means. When one looks at a small light source through a flask with moist air in which an adiabatic expansion is produced (for example, by sucking through a rubber tube) a coloured diffraction halo around the light source is seen. It is, however, not stationary, but at first moves inward during a fraction of a second. This must be attributed to an increase in the size of the fog droplets, due to the same finite diffusion-rate of the water vapour (and of the heat dissipation). Here the sink to be used in the calculation is the spherical droplet itself.

An Unusually Radioactive Fossil Fish from Thurso, Scotland

During recent investigations on the distribution of radioactive elements in phosphates[1], it was noted that many of the Old Red Sandstone fish remains from north-east Scotland have an abnormally high radioactivity; in particular an unidentified *Homostius* plate (GSM 89090) was shown by rough radiometric assay to have an activity equivalent to 0·5 per cent U_3O_8.

More detailed radiometric assays we have carried out indicated that this material is either in a state of secular disequilibrium, or contains appreciable amounts of thorium. As the latter alternative seemed the more likely, part of the specimen was assayed chemically (Radiochemical Group, Chemical Research Laboratory, Teddington) and found to contain 0·32 per cent U_3O_8 and 0·51 per cent ThO_2, a result which is in excellent agreement with the equivalent U_3O_8 value of 0·48 per cent obtained on the same sample. On obtaining chemical confirmation that appreciable thorium is associated with this particular fish plate, additional investigations were undertaken in an endeavour to obtain more information on the distribution of the radioactive elements within the plate.

In thin section the plate is opaque except where small amounts of interstitial calcite occur; but in polished section the bone structure can be seen clearly (Fig. 1). The bone cavities are filled with hydrocarbon or hydrocarbon partly replaced by calcite. Accessory minerals recognized in the polished sections are pyrite and chalcopyrite.

The mineral constituting the bone tissue was identified by normal optical methods and by X-ray powder photographs of an untreated sample, and of a similar sample ignited to destroy the associated hydrocarbon. Powder photographs of fluorapatite and of carbonate-fluorapatite were also taken for comparison purposes. The X-ray data on which the identification is based are given in Table 1.

It is apparent from the above observations that the apatite of the bone matrix has an *a* cell dimension between carbonate-fluorapatite and fluorapatite, but a *c* dimension somewhat greater than the other carbonate-fluorapatites examined. The refractive indices of the ashed material, ω = 1·628 and ε = 1·616, however, are in good agreement with carbonate-fluorapatite, and since fluorine and only a trace of chlorine were detected chemically (C. O. Harvey, Geological Survey and Museum), it seems reasonably certain that the Thurso material is in fact a carbonate-fluorapatite.

Table 1. Cell Dimensions of Some Varieties of Apatite

		a (in A.)	*c* (in A.)
1. Hydroxylapatite, Holly Springs, Ga., U.S.A.		9·413	6·875
2. Fluorapatite, Bob Lake, Canada		9·396 ± 0·005	6·879 ± 0·005
3. Fluorapatite, Durango, Mexico		9·386	6·878
4. Apatite from *Homostius* bone tissue, Thurso, Scotland	(Untreated)	9·356 ± 0·01	6·910 ± 0·01
	(Ashed)	9·366 ± 0·005	6·894 ± 0·005
5. Carbonate-fluorapatite, Staffel, Germany		9·344	6·881
6. Carbonate-fluorapatite, Florida, U.S.A.	(Untreated)	9·339 ± 0·005	6·894 ± 0·005
	(Ashed)	9·351 ± 0·005	6·885 ± 0·005

Determinations 1, 3 and 5 are by Z. S. Altschuler, E. A. Cisney and I. H. Barlow using an X-ray diffractometer. Abstract in *C.R. XIX Int. Geol. Congr. Algiers*, **11**, 9 (1952).

In determinations 2, 4 and 6 a 114·6-mm. diameter camera was used with copper *Kα* radiation and an internal standard of potassium chloride; *a* was determined from the reflexion $41\bar{5}0$ and *c* from 0004.

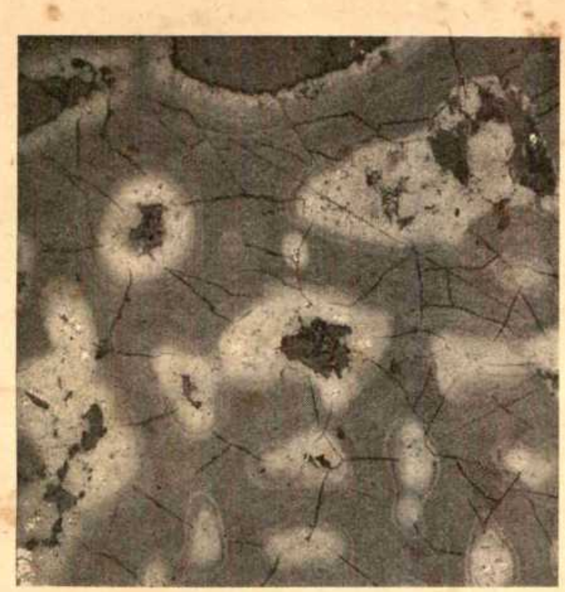

Fig. 1. Polished section of *Homostius* plate showing bone matrix (medium grey), hydrocarbon (light grey) and calcite (dark grey). The white specks are pyrite. × 45

Autoradiographs prepared from polished sections show that whereas both the bone matrix and the hydrocarbon are radioactive (Fig. 2), the alpha-track density of areas corresponding to the hydrocarbon is approximately 1·5 times that of areas corresponding to bone matrix. Measurements of the lengths of alpha-tracks clearly indicate that those of sufficient energy to be attributed to polonium-212 are present only in emulsion that had been in contact with the hydrocarbon, and it is therefore concluded that the thorium is concentrated in the hydrocarbon and does not occur in the bone phosphate. It was further shown from a comparison of the alpha-track population and the U_3O_8 and ThO_2 values obtained chemically that some uranium occurs with the thorium in the hydrocarbon.

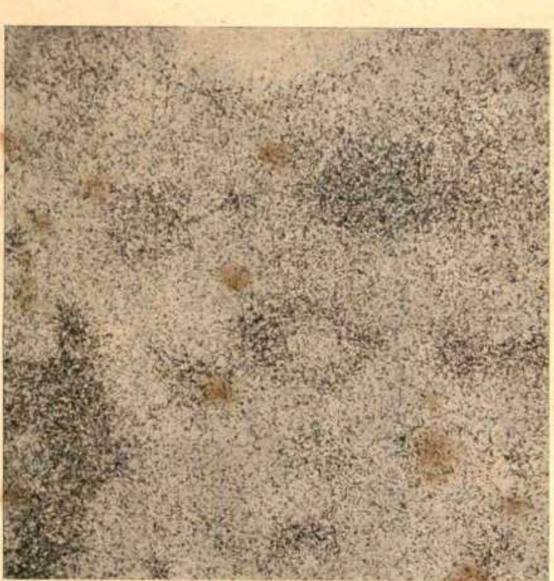

Fig. 2. Autoradiograph of same field as Fig. 1 showing concentrations of alpha-tracks corresponding with areas of hydrocarbon. The calcite is inactive. × 45

These observations indicate that whereas both uranium and thorium form organic complexes or compounds with hydrocarbon, only uranium is fixed by bone apatite under the conditions appertaining in this instance. Had the uranium and thorium been taken up under reducing conditions, it would have been expected that thorium (ionic radius 1·02 A. would have replaced calcium (radius 0·99 A.) in the carbonate-fluorapatite lattice in the same way as the tetravalent uranium ion (radius 0·97 A.) could have done; but since thorium is not present in the bone apatite, it is assumed that uranium is fixed by some other mechanism. The most likely method of fixation would seem to be that suggested by Neuman and his co-workers[2], in which the uranyl ion (UO_2^{++} combines with two adjacent phosphate groups at the surface of the bone apatite crystals and displaces a calcium ion. This type of exchange adsorption could explain such observed phenomena as the marginal concentration of uranium on apatite crystals, or fossil teeth, and on some phosphorite nodules. It also explains why uranium in ground-water is not substituted for calcium in other common calcium minerals.

We are indebted to Mr. J. E. T. Horne for his assistance in deriving the X-ray data. The communication is published by permission of the Director of the Geological Survey and Museum.

Differences in Proportion of Fawns to Hinds in Red Deer (*Cervus elaphus*) from Several New Zealand Environments

From more than a hundred liberations, between 1851 and 1923, red deer have spread into the majority of forested areas in New Zealand. In the present communication autumn fawn/hind ratios in New Zealand are compared between five different areas and within each area on two successive years, 1952 and 1953.

The relative proportions of fawns to hinds are shown in Table 1, where hinds are given an arbitrary value of 100. Samples of deer were taken in autumn for comparison with ratios available on deer in the northern hemisphere.

New Zealand fawn/hind ratios show highly significant differences in the five environments tested. Fawn/hind ratios range from 28(±10)/100, in the Central North Island, to 70(±14)/100 in the Nelson–Marlborough area, South Island (Table 1). Such differences perhaps could be expected in New Zealand, as red deer range over a wide variety of contrasting environments. Similarly, for adult stags in autumn, differences in fat reserves have recently been demonstrated for several different New Zealand environments[2].

Fawn/hind ratios varied more between different areas than similar ratios taken from the same area

Table 1. FAWN/100 HIND RATIOS FOR RED DEER (*Cervus elaphus*) FROM FIVE NEW ZEALAND AREAS

Area	Total animals	Fawns/ 100 Hinds	Approx. 90 per cent confidence limits
Central North Island	134	28	± 9 8
Nelson–Marlborough	284	70	± 13·9
Canterbury	224	39	± 9·6
Southern Lakes	272	47	± 10·1
South Westland	96	35	± 13 5
All areas	1,010	47	

Corrected χ^2 (ref. 1) to test differences between the areas was 20·62, with a probability of a greater value 0 0004. Approximate 90 per cent confidence limits were calculated using the formula

$$\frac{100F}{H} \pm \left(100\sqrt{\frac{(F+H)F}{H^3}}\right) 1\ 6449.$$

for two consecutive years. Three of the five areas showed no significant difference between fawn/hind ratios taken in 1952 and 1953. Values for the three areas were: Central North Island, 27/100–31/100 ($\chi^2 = 0{\cdot}023$); Nelson–Marlborough, 67/100–75/100 ($\chi^2 = 0{\cdot}228$); and Southern Lakes, 48/100–47/100 ($\chi^2 = 0{\cdot}00015$).

Southern Lakes, South Westland, Canterbury and Central North Island habitats include most of the deer population in New Zealand. Fawn/hind ratios from these four areas combined (41($\pm$4)/100) correspond closely to those recorded by Alex-Hansen[3] from Jutland (38·5/100), near the northern limit of the range of the European red deer, and are significantly less ($\chi^2 = 6{\cdot}84$) than those ratios of 60/100 recorded from Scotland and Germany by Darling[4] and Müller-Using[5] respectively.

Grateful acknowledgment is made to those Government shooters who co-operated in recording results of unselective shooting to make these data available. This work was done while I was employed by the Department of Internal Affairs. The formula for approximate 90 per cent confidence limits was supplied by the Applied Mathematics Laboratory, Department of Scientific and Industrial Research, New Zealand.

The Reniform Nematode in the Gold Coast

THE reniform nematode (*Rotylenchulus reniformis*) was first described as an obligate parasite on the roots of many plants in Hawaii[1], and a list of sixty-five hosts was given by Linford and Yap[2]. Subsequent records[3-5] have added a further five hosts from the United States.

The occurrence of the reniform nematode has now been noted on a number of hosts at three sites in the Gold Coast, West Africa.

Plants on which this nematode has been found capable of egg production in the Gold Coast are: *Amaranthus spinosus* L.*, *Citrus limon* Burm. f.*, *Crotalaria juncea* L., *Crotalaria striata* D.C., *Daucus carota* L. var. *sativa* D.C., *Glycine max* Merr.*, *Hibiscus esculentus* L., *Ipomoea batatus* L.*, *Lycopersicon esculentum* Mill., *Manihot esculenta* Grantz.*, *Nicotiana tabacum* L., *Persea americana* Mill.*, *Poinciana pulcherrima* L.*, *Solanum melongena* L. var. *esculentum*, *Sorghum vulgare* Pers., *Synedrella nodiflora* Gaertn.*, *Vigna sinensis* Endl., and *Zea mays* L. Those marked with an asterisk are new host records for the reniform nematode.

Life-history studies suggest that the West African forms have a shorter life-cycle than those described by Linford and Oliveira[1]. Soya grown from seed in soil infested with *Rotylenchulus* contained swollen forms after four days, mature females with gelatinous matrix after seven days; egg-laying commenced at ten days, and, fifteen days after sowing, second-generation larvæ were hatching within the egg-masses.

All three sites were old centres of European cultivation within fifteen miles of the capital, Accra, so it is not possible to say whether the reniform nematode is indigenous to the Gold Coast. A more detailed account will be given elsewhere at a later date.

I wish to thank Dr. J. B. Goodey, Nematology Department, Rothamsted, and Dr. S. A. Sher, Division of Plant Nematology, Riverside, California, for help and advice.

Regulation of Outbreeding in Field Beans (*Vicia faba*)

IT has been reported that field beans show about 30 per cent of cross-fertilization in eastern England[1], and rather more in eastern France and Germany[2]. In the course of some pollination experiments at the Plant Breeding Institute, evidence has been obtained of a natural regulating mechanism which stabilizes this breeding structure.

The plants studied came from commercial seed, inbred lines, and F_1 hybrids, and were grown in an insect-proof glasshouse. Several self- and cross-fertilization treatments were applied, and the results of three of these are set out in Table 1, expressed as the mean number of seeds obtained per flower treated.

It can be seen that, on inbreeding, the ability to set seed without some manipulation of the flower was progressively lost. In most cases it was immaterial whether self- or cross-pollen was applied, except in the more advanced inbreds, where cross-pollen was more effective, possibly indicating some degree of self-incompatibility in this group. On hybridization,

Table 1

Group	Treatment		
	a	*b*	*c*
Commercial sample	0·56	2·97	2 89 ± 0·266
Second-generation inbreds	0·27	2·13	1·87 ± 0·158
Fourth-generation inbreds	0·04	1·42	2·14 ± 0·123
F_1 hybrids between third-generation inbreds	1·36	1·98	2·09 ± 0·133

(*a*) *Control*: flowers left untreated. (*b*) *Artificial self-pollination*: keel of mature flower depressed to push self-pollen on to the stigma. (*c*) *Mixed pollination*: as (*b*), but foreign pollen placed on stigma in addition to self-pollen already there.

spontaneous self-fertility was restored; in fact, in this respect the hybrids surpassed the commercial sample.

In the field, flowers may be pollinated by bees (similar to treatment *c*) or pods may be formed from unvisited flowers (as in treatment *a*). The results above suggest that although all types will be equally fertile after bee pollination, those plants arising from cross-fertilization in the previous year will set more seed from unvisited flowers than others in the population. As seed set in the absence of bee visitation must be entirely self-fertilized, this will mean that cross-bred plants will bear a higher proportion of selfed seed than plants derived from one or more generations of self-fertilization.

This unusual breeding behaviour has several important consequences :

(1) The ability of some plants to set seed on unvisited flowers ensures maintenance of the population even in years of low bee activity.

(2) The distribution of this self-set seed mainly on the more heterozygous members of the population restricts the rate of fixation of genetic variability under these conditions.

(3) The undiminished fertility of the inbred plants when pollinated by bees promotes rapid remixing of genetic material under favourable conditions.

The overall effect will be to maintain the population in a stable state of intermediate heterozygosity, in spite of disturbing factors such as seasonal variation in the level of bee activity, and the selective elimination of inbred plants under adverse environmental conditions.

The regulating mechanism described is of interest as it represents a means of maintaining a moderate degree of heterozygosity without complete dependence on insect pollinators.

Cytogenetics of South American Orthoptera

THIS is a preliminary report of an investigation in progress dealing with cytogenetics of orthopteran insects of the southern hemisphere belonging to the family Acrididae and new to cytology. In this report the number of chromosomes is established, taking specially into account the existence of metacentric chromosomes. We have studied thirty-two species of four subfamilies, as shown in Table 1.

In *Aleuas brachypterus*, *Diponthus maculiferus*, *Ommaexecha servillei* and *Dichroplus pratensis*, the reduction of chromosome numbers has taken place by centric fusion of two acrocentric (rod-shaped) autosomes, whereas in *Tropinotus laevipes*, *Atrachalacris unicolor*, *Dichroplus bergi* and some forms of *D. pratensis* this evolutionary change took place between autosomes and sex chromosomes, producing in this case an XY–XX sex-determining mechanism by formation of a neo-Y, neo-X system in the male[1].

Table 1

Species	Diploid number $2n$ (♂)	No. of metacentrics	X-chromosome	No. of chromosome arms
Subfam. Acridinae				
Dichroatettix bohlsi (Giglio-Tos) Rehn	23	—	free	23
Hyalopterix rufipennis Charpentier	23	—	free	23
Staurorhectus longicornis G. Tos	23	—	free	23

Subfam. Ommexechinae				
Ommaexecha servillei Blanchard	21	2	free	23

Particularly interesting is the genus *Dichroplus*, which shows interspecific variation in the number of chromosomes. As Table 1 shows, there is a numerical series ranging from the ancestral karyotype $2n$ (♂) = 23 to the surprising number of $2n$ (♂) = 8. Some forms of *D. pratensis* give 18 diploid chromosomes, while the number of major chromosome arms is not reduced, remaining 23. Other forms of this genus, on the contrary, have also 18, but the number of arms is reduced to 19, which means that four chromosomes have probably been lost.

The rather striking extreme case is the brachypteran form of *Dichroplus* that shows eight diploid elements, meaning that eleven chromosomes had been lost of the original complex. In these individuals the sex chromosome does not behave as an odd element, since it is associated with a small chromosome so as to form a heterozygous acrocentric bivalent, segregating in the first meiotic division as an X–Y complex.

British Psychological Society (in the Gustave Tuck Theatre, University College, Gower Street, London, W C 1), at 2 30 p.m —Dr. L Weiskrantz · "Some Effects of Temporal Lobe Lesions on Behaviour in Monkeys"

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant (preferably with a degree in one of the natural sciences) in Charge of the Natural Sciences Library—The Registrar, University College, Singleton Park, Swansea (March 17).

Senior Scientific Officer (with a degree of high standard, with chemistry as a major subject, and several years research experience, and preferably with a knowledge of paint technology) in the Defence Standards Laboratories, Department of Supply, Maribyrnong, Victoria, Australia, for research and developmental work in connexion with paints, such as the study of methods of measuring the properties of paint films and changes in properties during ageing and weathering, the study of the protection of metals by primers, underwater protection of ships and anti-fouling paints—The Senior Representative (AP.45), Department of Supply, Australia House, Strand, London, W.C.2 (March 19).

Forestry Assistant (with a recognized degree or certificate in forestry) for duties which will include the preparation of Tree Preservation Orders and planting schemes, management of woodlands, consideration of felling licence applications and general liaison with the Forestry Commission—The Planning Officer, Peak Park Planning Board, Aldern House, Bakewell, Derbyshire (March 21).

Research Worker (with an honours degree in biochemistry or equivalent qualification) in the Department of Biological Chemistry, to assist in work on the metabolism of the autotrophic nitrifying bacteria—Prof. W. O. Kermack, Department of Biological Chemistry, Marischal College, Aberdeen (March 24).

Scientific Officer (with a good honours degree in science) in the Cereals Section, to engage in genetical, physiological and breeding research, and an Assistant Experimental Officer (with a degree in agriculture or horticulture) for duties as Glasshouse and Plot Manager—The Secretary, Plant Breeding Institute, Trumpington, Cambridge (March 26).

Lecturer in the Department of Fluid Mechanics—The Registrar, The University, Liverpool (March 29).

Lecturer (with an honours degree and practical experience in public works engineering) in Civil Engineering—The Registrar, The University, Leeds 2 (March 31).

Lecturer or Assistant Lecturer in Agricultural Zoology, and a Lecturer or Assistant Lecturer in Crop Husbandry at Makerere College (University College of East Africa)—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (April 2).

Senior Lecturer (with a good academic qualification, and wide teaching and/or research experience, in tropical agriculture) in Tropical Agriculture at Kumasi College of Technology—The Appointments Secretary, Advisory Committee on Colonial Colleges of Arts, Science and Technology, 1 Woburn Square, London, W.C.1 (April 7).

Chair of Medicine at St Mary's Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 19)

Chair of Physical Chemistry at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, April 20).

Imperial Chemical Industries Research Fellows in Chemistry, Physics and allied subjects, for example, pharmacology, engineering and metallurgy—The Registrar, The University, Manchester 13 (April 30).

Keeper of the Department of Archæology—The Director, National Museum of Wales, Cardiff (April 30).

Lecturer (entomologist, preferably with research interest in insect pests of stored products in the tropics) in Zoology at the University College of the West Indies—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (April 30)

Professor of Mechanical Engineering at the University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, April 30).

Senior Lecturer in Inorganic Chemistry at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, April 30).

Lecturer (with practical experience of forestry in Great Britain) in the Department of Forestry—The Secretary, The University, Edinburgh (May 31)

Professor of Agriculture, and a Professor of Botany, at the Imperial College of Tropical Agriculture, Trinidad, British West Indies—The Secretary, The Imperial College of Tropical Agriculture, 40 Norfolk Street, London, W.C.2 (June 1).

Aerodynamicists and Mathematicians (with a first- or second-class honours degree or equivalent, and preferaby with some research or development experience) with the Ministry of Supply at various Experimental Establishments and London Headquarters, for research and development work on aircraft projects, performance analysis of aircraft and weapons, statistics and operational research, guided weapons, gas turbines—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.69/6A/AA.

Demonstrator in Chemistry (inorganic, organic and physical)—The Secretary of University Court, The University, Glasgow.

Engineers and Physicists (particularly with electronics), Senior Scientific and Scientific Officer grades (with a first- or second-class honours degree or equivalent high professional attainments) at Royal Naval Scientific Service Experimental Establishments chiefly in the Weymouth and Portsmouth areas, and the Home Counties—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.344/5A.

Lecturer in Physical Testing of Rubber-like Polymers, and a Senior Lecturer in Plastics Technology—National College of Rubber Technology, Northern Polytechnic, Holloway, London, N.7.

Master to teach Mathematics up to university scholarship standard—The Headmaster, Trent College, Long Eaton, Nottingham.

Principal Scientific Officer (with a first- or second-class honours degree in physics or electrical engineering, and considerable experience of servo systems and other electrical mechanical devices) at the Royal Aircraft Establishment, Farnborough, to lead a section engaged in research and development of automatic flight controls—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.76/6A/AA.

Research Assistant (with a special interest in plant physiology) in Botany—The Secretary, Bedford College (University of London), Regent's Park, London, N.W.1.

Scientific Officer (Chemist), Assistant Experimental Officer (Chemist), and an Assistant (Scientific), in the Metropolitan Police Laboratory—The Secretary, Room 165, New Scotland Yard, London, S.W.1.

Technician (preferably with some experience in geology) for research in micropalæontology—The Secretary, University College, Gower Street, London, W.C.1, quoting 'Geology/B.P.'.

Cut copying time

with this 'one-step' paper

You copy documents with greater speed when you use Kodak 'Autopositive' Paper, because it gives you black-on-white photo-copies in one step, without intermediate negatives.

'Autopositive' paper's low-speed emulsion enables it to be processed in ordinary office lighting or indirect daylight. It has the high contrast and the "whiter white" base that are features of most 'Kodak' document-copying papers. You can make clear copies every time —even when the originals are faded.

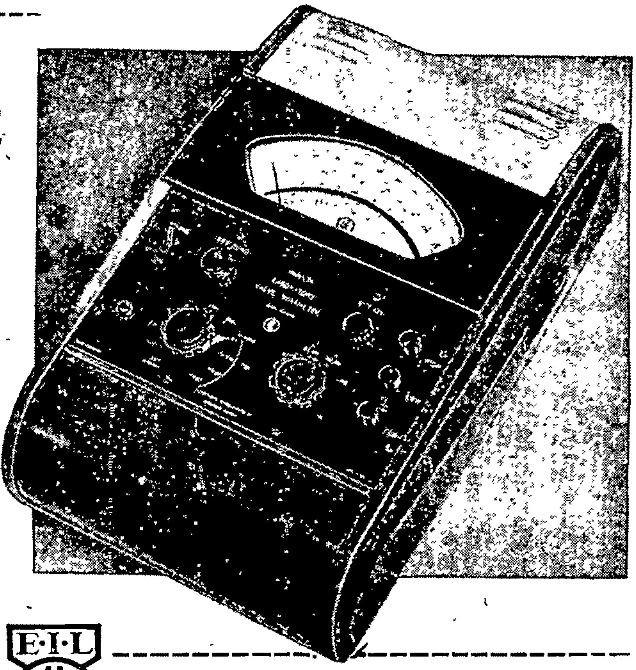
Kodak

'AUTOPOSITIVE' PAPER

Please write (mentioning 'Nature') for the booklet "Document Copying Papers" and a free wallet of specimen prints.

Kodak Limited, Industrial Sales Division, Kodak House, Kingsway, London, W.C.2

The names 'Kodak' and 'Autopositive' are trade marks and can properly be applied only to products made by Kodak Limited.



MODEL 26

LABORATORY VALVE VOLTMETER

A precision instrument intended for research work and as a laboratory standard. It measures d.c. and a.c. voltages from 0.2 to 250 v. with an upper frequency limit of 200 Mc/s. It measures resistances from a few hundred ohms up to 500 megohms and power level variations over a wide range of decibels. Multipliers for 1,000 v and 2,500 v d.c. and a.c. are available. Each meter is individually calibrated so as to enable full advantage to be taken of the accuracy of the instrument which on all d.c. and low frequency a.c. ranges conforms to B.S.S. 89: 1954 for industrial moving coil meters.

SAFETY AND HEALTH IN INDUSTRY

THE annual reports of the Chief Inspector of Factories are primarily of interest to those directly concerned with health and safety in industry in Britain, and in so far as both health and safety depend increasingly on the knowledge and co-operation of the scientist, these reports are invariably of scientific interest. They often, however, are of a wider scientific or technical interest, as is well illustrated by the latest of these reports, that for the year 1954*. While particular and general trends in safety in health, welfare and hours of employment are reviewed in sections of the report devoted to these subjects, they are preceded by an introduction which gives a most useful survey of industrial developments during the year, bringing out a number of features of special interest to the scientist as well as to the technologist.

It is not surprising to find that the report notes that the factory population was the highest yet recorded in times of peace; but the number of power factories registered at the end of the year was 212,909, as against 214,020 at the end of the previous year, and the number of non-power factories also decreased from 21,032 to 18,955. The increase in the total number of persons employed is due to increases in the number of medium- and larger-sized factories, and for the second time since the War there was an appreciable increase in the total number of accidents —in factories from 158,597 to 161,458—but the accident-rate was slightly less. Doubt is expressed as to whether the same attention is being given to the training of women and girls as is given to that of men and boys, and while the importance of the human factor in accident prevention is far more widely realized than formerly, this report brings out well the supreme importance of management in effective organization for preventing accidents.

This is a point where the scientist or the technologist is directly concerned. It is not so much that his knowledge is required in devising appropriate measures, as that his interest is a vital factor in obtaining the necessary enthusiasm on the part of the works manager, the shed superintendent, the foremen and supervisors. Unless that is secured, it is almost impossible to make the worker himself aware of the part he can and should play in preventing accidents. In the present man-power situation, the elimination of loss of man-power due to accidents or sickness is of fundamental importance to Britain's economic effort, quite apart from those humanitarian considerations which will normally prompt every scientist or technologist to play his full part in preventing avoidable human suffering. The growing shortage of skilled and technically qualified workers during the past four years has enhanced the importance of training schemes for apprentices and others, and such training for production should never be divorced from training for safety. From the same economic consideration, the evidence presented in this report that the accident-rates for those aged sixty or more are less than for those in the prime of life is of general interest; but it should also be noted that quite small adjustments may make the lot of the elderly worker more comfortable and even safer. Apart from the slight contribution thus made to improving the man-power situation, such adjustments often have the further advantage that the older workers can retain their usual jobs with efficiency.

The importance of minor improvements in Britain's man-power resources is the more apparent in the light of the trends in industrial development stressed in this report. For example, trends in the design of factory premises are in the direction of single-story buildings with wide-span roofs; the particular example cited of retort houses in the gas industry, in which the gas producers are now built separate from, instead of integral with, the retorts, gives, with welded portals, a clear and unobstructed working space, and much improved lighting and ventilation, so providing conditions which are particularly helpful for the older worker. Again, the modern tendency to house chemical plant in a light weather-proof structure, besides being economical, greatly reduces the risk of explosion due to accumulation of inflammable dust or gases, while since much of this plant is remotely controlled and there are no men working full-time on it, no hardship is caused to operators. The report also emphasizes that mechanization of production continues to increase, particularly in industries in which raw or finished materials are handled in bulk, and sometimes the whole pattern of the manufacturing process is altered in consequence, while in a wide range of industry continuous methods are replacing batch processes.

Some of these last provide examples of one of the two particular trends to which the report directs attention. Methods of automatic production in one form or another have been a growing feature of industrial development for many years, and the real novelty of the present phase known as 'automation' lies in developments in the field of electronics during and since the Second World War. These, in turn, have led to entirely new conceptions of the master control of machinery and processes by means of a device called a computer, one type of which will issue predetermined 'orders' fed into it by means of punched-paper tape or magnetic tape. In this way, the operation of a machine or a series of machines may be controlled, quite independent of human intervention, to ensure that the final product comes up to specification.

The uses of automation, however, are not confined to the machine shop. It is beginning to appear, for example, in the manufacture of petroleum chemicals, where the levels of liquids in large tanks or other containers can be accurately controlled, variations caused by fluctuating input or output being compensated. Further, it is possible in some cases by electronic means to draw off samples at various stages of the process, analyse them automatically and record the analyses by graphical means, the whole process being conducted on an instrument plant which may be several hundred yards away from the plant.

---

* Annual Report of the Chief Inspector of Factories for the year 1954. Pp. 265. (Cmd. 9505.) (London: H.M. Stationery Office, 1955.) 8s. net.

We are only at the beginning of such developments, but the report does not encourage excessive claims for the speed with which the automatic factory will be introduced. It is stated that automation has a considerable future in Britain for mass-production work, where long lines of the same type of product can be assured by public demand ; but even in these fields no drastic overnight change is envisaged, and the automatic factory, full of complicated machinery controlled by only a few people, will take a long time to develop. None the less the importance of these trends has been noted by thoughtful people, and the whole subject is receiving serious consideration by those responsible for the future pattern of industry. The Factory Department believes that automation will eventually enhance the cleanliness as well as the safety of the factory. Automatic handling, too, is bound to increase and should eliminate many accidents in handling goods and materials.

While the report points out that, without an increase in shift working, automation would be uneconomic, it does not otherwise touch on the two most important implications of such developments. The first is one that is emphasized elsewhere in the report in discussing accident prevention. Just as the latter demands the full co-operation and understanding of the workers themselves, so the introduction of automation demands the co-operation and understanding of all those affected. It is not simply a matter of gaining their consent to shift-working. It means equally that the implications of redundancy and the transfer of labour, and not least the educational issues, must be fairly faced and frankly discussed with all concerned.

There is evidence enough in this report to show that not all managements have appreciated the importance of such co-operation and understanding even in relation to accident prevention. If Britain is to benefit to the full from the possibilities of automation, and to hold her position in competition with other nations who are adopting such methods, we must make full use of the breathing-space that the slow rate of introduction predicted in this report affords us to prepare the way for the changes and adjustments that will be required. The remarks on this subject should be weighed alike by trade unions and managements.

The implications of automation for technical education require particularly careful consideration ; no plans for the expansion and development of the technical colleges are adequate for Britain's economic future if, in concentrating on the supply of technologists or even technicians, they ignore the needs of some measure of technical education for an increasing proportion of the operatives in industry. Here again is a matter demanding urgent attention, and much keener thinking than it appears to have received as yet. Its importance, moreover, is also emphasized by some of the comments in this report on the second of the particular trends in industrial developments which are noted, as well as in the remarks on the extension of electric supply and the use of electricity.

This second trend is the development of radiology in industry. This section of the report demonstrates more clearly than any other both the dependence of safety on the vigilance and co-operation of the scientist and technologist and the importance of technical education for those called upon to handle the apparatus and processes involved. The increasing use of gamma-ray radiographic sources seems to have supplemented rather than supplanted the use of X-rays for the radiography of castings and welds, and it is satisfactory to note that in recent years very few gamma-radiographic rooms newly built or specially adapted for the purpose have failed to meet the standards of the Factory Department. The rapid development of the electronics industry has increased the need for equipment incorporating piezo-electric quartz crystals serving as oscillators, resonators and frequency standards, and the cutting of these quartz crystals in the correct orientation depends largely on the use of X-ray crystallographic test equipment ; the precautions to be taken in using this equipment were reviewed during the year in collaboration with the X-ray Analysis Group (Equipment Sub-Committee) of the Institute of Physics. As a result, the appropriate section in the Department's pamphlet, "Precautions in the Use of Ionizing Radiations in Industry", was revised when the pamphlet was reprinted in August 1954.

Iridium-192 continues to be the source most commonly used in industry for gamma-radiography. Use of tantalum-182 has practically disappeared, and thulium-170 has only gained slightly in popularity. Cobalt-60 provided the strongest gamma-ray sources used during 1954 in Britain for the radiography of castings and welds. The increasingly powerful sources of gamma-radiation being used by industry require corresponding advances in the design of their protective and operating containers, and during the year two manufacturers marketed new models of containers suitable for use with cobalt-60 sources up to about 10 curies in strength. Some incidents occurred during the year in connexion with radiographic sources and other radioactive materials, fortunately without serious consequences, though affording valuable lessons, of which due notice is being taken in considering statutory regulation. In view of the unique way in which radioisotopes can be used industrially to follow the mechanism of chemical, physical, engineering and biological processes, it is surprising how few uses are made of these materials as tracers in premises coming strictly under the Factories Acts. In this field the research laboratories attached to factories and the research stations of the Department of Scientific and Industrial Research have been far more active, and in various studies, including the location of gas leaks, the travel of coal in retorts, paint sedimentation, metal extrusion and electroplating and mould metabolism, some eighteen radioisotopes are listed as having been used.

The scientific interest of the Factory Department's work is particularly apparent in such recent developments, though it is equally to be seen in the Department's research work designed to limit the dangers of explosions of dust, carried out in collaboration with the Department of Scientific and Industrial Research at the Safety in Mines Research Station, Buxton. Here attention is being turned, at the request of the Central Electricity Authority, to the problem of protecting the pulverized fuel plant used in power stations. Schemes of research with the object of limiting the explosions of gas and vapour have also been prepared, and it is hoped that they will be put into operation shortly, with the co-operation of the Department of Scientific and Industrial Research and the Ministry of Fuel and Power.

One encouraging feature of the report in regard to health in industry is that the general improvement in working conditions—such as cleaner premises, lighter and more cheerful surroundings, better washing and cloakroom facilities—is gradually changing the attitude of the operatives. They are tidier in themselves and more appreciative of the amenities provided. Most firms go well beyond legal requirements in regard to working conditions, though much could still be done to provide more comfortable conditions if thought were given to the use of modern equipment, to the provision of thermal insulation for the building and to the prevention of draughts. Substantial progress has also been made in the provision of natural and artificial lighting, and here again, while the scientific and technical expert has his part to play and perhaps is especially responsible for the initiative, the really encouraging feature is the evidence that the operatives respond when management takes the lead and seeks to stimulate their interest.

The report of the Chief Inspector of Factories makes it abundantly clear that the scientist and technologist have a decisive contribution to make to safety and health in industry, and that contribution is not made solely or even mainly through the 361 inspectors employed by the Factory Department, to the quality of whose work, efficiency and tact the report bears impressive witness. Industrial safety and health, like industrial efficiency, depend even more on the unceasing vigilance of the chemist, the physicist and the engineer, employed in industry at whatever level from works manager to process control, research, testing or construction. Much depends on their insight and initiative, their ability to co-operate with foremen and supervisors and operatives, and, though it is true that the Factory Department is finding difficulty in recruiting staff to fill its existing vacancies, it is not only as factory inspectors that those with scientific and technical qualifications can find expression for their concern for human welfare in industry. It is from within industry, by and large, that the attitude of management must be changed where necessary, not simply to fulfil existing requirements or to conform to the best practice rather than the legal minimum, but still more to undertake the constructive thinking that the adoption of new methods such as the change-over from batch to continuous processing, the introduction of new materials and new techniques like radioactive tracing, and, even further, the use of electronic and fully automatic methods demand.

The report gives no reason for doubting that it is possible to secure the necessary co-operation of the workers and their unions; but it will not be done without frankness, clear thinking and openmindedness on the part of unions as well as management. The Chief Inspector of Factories suggests that we still have time for such thinking, and for making adequate preparations for the changes required. This report for 1954 is valuable for the glimpse it gives of some of the problems which Britain must face if she is to adapt her economy to an age in which automation, nuclear power and radiology play an increasing part in industrial development. It is above all to be valued for its challenge both to unions and managements to face those implications as a matter of urgency, and to work out in co-operation and as expeditiously as possible the changes in industrial practices and in technical education which are required to enable Britain to enjoy the full benefits of technological advance with the minimum disturbance to industry or society.

FREUD'S "INTERPRETATION OF DREAMS"

The Interpretation of Dreams
By Sigmund Freud. (Translated from the German and edited by James Strachey.) Pp. xxxii + 692. (London: Allen and Unwin, Ltd., 1954.) 21s. net.

FREUD always looked on "The Interpretation of Dreams" as his most important work. This and the "Essays on the Theory of Sexuality" were the two publications that he regularly strove to keep up to date as fresh editions were required. Substantial additions and omissions, sometimes even entirely new sections, progressively appear in the seven German revisions, and Mr. James Strachey's version is in effect a *variorum* edition: every important departure from the original text is clearly indicated and dated, so that the inquiring reader is enabled to trace the gradual evolution of Freud's views.

The editor has furnished a long and valuable introduction, with illuminating quotations from Freud's own letters written both before and after the book appeared. As early as 1895, five years before it was published, Freud relates how, "not long ago, I was obliged to exchange my usual bed for a harder one; and, having as a result more numerous and more vivid dreams, I took the trouble to write them out and tried to solve them". A few months later he set down on paper a "Project for a Scientific Psychology" (recently published as an appendix to his correspondence with Fliess); and in the concluding part of the manuscript he sketches his first attempt at a coherent theory of dreams. Here he put forward the novel and epoch-making suggestion that permeates the book itself, and so many of his later writings, namely, the close analogy between the mental mechanisms underlying dreams and those underlying neurotic symptoms.

One of the chief difficulties felt by the academic psychologist in assessing Freud's theory springs, as Mr. Strachey points out, from the fact that many of its basic concepts—"mental energy", "sum of excitation", "cathexis", and the like—are left undefined. In the "Project", however, we learn that "scientific psychology", as Freud originally conceived it, was to be formulated in terms of the anatomical doctrine of the neurone, which had recently been developed by German neurologists. This he proposed to combine with Helmholtz's doctrine that neural activity, like other physiological processes, must be interpreted in accordance with the principles of the conservation and transformation of energy. An inevitable corollary was the postulate of strict determinism which underlies his whole theory of dreams.

The working model elaborated on this twofold basis was curiously like that independently suggested by William McDougall in Britain a few years later. But, like McDougall, Freud quickly discovered that, when dealing with the mental processes of the individual, the only intelligible description would be one that is expressed in psychical rather than physiological terms. This radical change, as both writers recognized, involved the assumption that some of the most important processes in the mind must be regarded as wholly unconscious—a doctrine which eventually became the keystone of all Freud's theories. Accordingly, in "The Interpretation of Dreams" we no longer hear of "nervous excitation" flowing across the "contact-barriers" that separate one system of neurones from another, but of unconscious "wishes" tending automatically to fulfil themselves in the face of unconscious "resistance". But, despite this drastic change in vocabulary, the structural pattern attributed to the mind remains much the same as in the scheme originally outlined for the earlier interpretation in anatomical terms. Mr. Strachey, both in his introduction and in his explanatory footnotes, works out the parallel in some detail; and his explanations do much to elucidate the obscurer and more paradoxical features of Freud's own exposition.

Freud's style, as he himself realized, is tortuous and abstruse, with "involved and trailing sentences, bolstered up with sidelong glances and indirect phrases" (his own self-criticism). Mr. Strachey's translation, which is entirely new, skilfully surmounts the difficulties thus presented to the English-speaking student. At times the puns, the associations, the colloquial *double entendres*, on which many of the interpretations turn, are so peculiar to the German tongue that previous translators in despair have omitted many of the most typical dreams and even substituted examples of their own, either genuine or invented *ad hoc*. Mr. Strachey, quite rightly, has decided to keep scrupulously to Freud's own narrative, quoting and annotating the German where occasion demands. The index, bibliographies and supplementary notes are invaluable. As a result, both the psychological specialist and the general reader now have available a richly documented edition of what is after all one of the most original contributions to science published during the present century.

Cyril Burt

ANTIBIOTICS

Antibiotics Annual, 1954–1955

Proceedings of the Second Annual Symposium on Antibiotics. Edited by Dr. Henry Welch and Dr. Felix Marti-Ibañez. Pp. ix+1154. (New York: Medical Encyclopedia, Inc.; London: Interscience Publishers, Ltd., 1955.) 10 dollars.

Assay Methods of Antibiotics

A Laboratory Manual. By Dr. Donald C. Grove and Dr. William A. Randall. (Antibiotics Monographs, No. 2.) Pp. xxvi+238. (New York: Medical Encyclopedia, Inc.; London: Interscience Publishers, Ltd., 1955.) 5 dollars.

FOR anyone with an unsated appetite for new literature on antibiotics, the first of these volumes will indeed come as a bumper annual. This formidable mental meal constitutes the proceedings of the Second Annual Symposium on Antibiotics held in Washington, D.C., in October 1954. In format and content it is virtually indistinguishable from *Antibiotics and Chemotherapy* and *Antibiotic Medicine* and is, in fact, produced under the same auspices as these two journals. With more than 1150 pages and 172 papers, it almost equals in size their combined output for the year 1955 and clearly comprises a sizable part of the current literature on antibiotics. It is a pity, therefore, that those not attending the symposium had to wait some eight months—at any rate in Britain—for these admittedly well-produced proceedings.

The subject of antibiotics seems still to be in the exponential stage of development—no doubt because growth is plentifully nourished by dollars—and this volume gives an interesting cross-section of the subject towards the end of 1954. Thus, antibiotics are reported to be active *in vitro* or effective *in vivo* not only against a widening range of bacteria but also against viruses, yeasts, fungi, protozoa, and even tumour cells. Fourteen new antibiotics are reported. Many clinical papers deal with the use of established or newer antibiotics or of combinations of them with each other or with hormones or drugs, in a variety of maladies. Nearly fifty papers deal with some aspect of the tetracyclines. There is a timely summary of the untoward effects of the indiscriminate use of antibiotics, and a plea for the better training of physicians and medical students in their rational use. Greatly enhanced requirements are foreshadowed by the papers dealing with their place in veterinary medicine, animal husbandry and horticulture. All but seven of the papers are by Americans, though representatives of thirty-five nations were said to have attended the symposium.

The second of the volumes under review, instead of offering yet more new facts and theories about antibiotics, presents a neatly digested résumé of reliable methods for their assay, detection and testing. The names of the authors, and the fact that they write from the Antibiotics Division of the United States Food and Drug Administration, inspire confidence in the methods even when they are not the official Administration methods, and this confidence is enhanced the more one studies the book. The attitude is, not unnaturally, uncompromisingly American, and of the thirty-five references cited only two originate outside the United States. It follows that one will look in vain for certain methods much used in Britain, such as microbiological assays on large plates.

Successive chapters are devoted to penicillin, streptomycin, the tetracyclines, chloramphenicol, bacitracin, tyrothricin, polymixin, neomycin, erythromycin, carbomycin, viomycin, fumagillin, nystatin and anisomycin. Each chapter (with some exceptions) has four sections, dealing in turn with microbiological methods of assay, physical and chemical methods, assay of salts and pharmaceutical preparations, and determination in body fluids, tissues and animal feeds. Next follow chapters on the assay of mixtures of antibiotics—sixty-three mixtures are listed, mostly containing two active components—and on the identification of antibiotics by qualitative tests, by infra-red and ultra-violet absorption spectra (thirty-seven such spectra are given) and by optical and crystallographic properties. The procedure and specified amounts of various preparations to be used in toxicity, pyrogenicity and sterility tests; the determination of bacterial sensitivity to antibiotics; a chapter of miscellaneous tests and methods; and a list of media, buffers, reagents and apparatus conclude this unique book.

Discussion, where it occurs, is informative and brief; practical instructions are admirably clear and concise. Although, as mentioned, this book is selective and American in outlook, it contains a very large amount of useful information which it would be almost impossible to track down in the literature. One suspects that a good deal of it is being published here for the first time and is drawn from a critically accumulated store of experience. Anyone concerned with antibiotic assay or the other aspects covered here—whether through active interest or reluctant compulsion—will turn to this book with gratitude, tempered perhaps with momentary irritation that a method he values may not even be mentioned.

N. G. HEATLEY

MEASUREMENT AND APPLICATION OF NUCLEAR MOMENTS

Nuclear Moments

By Prof. Norman F. Ramsey. (Reprinted in part from Segrè (Editor), Experimental Nuclear Physics, Vol. 1.) Pp. x+170. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1953.) 40*s*. net.

PROF. N. F. RAMSEY'S book on nuclear moments gives for the first time a comprehensive account of a series of experimental methods, the rapid development of which since 1945 has contributed so much to our knowledge of nuclear physics, of the solid state and of chemistry. Starting with two short chapters dealing with the elementary theoretical aspects of the interactions between nuclear moments and the electromagnetic field, he soon launches into an admirably lucid account of the various methods now available for the measurement of these interactions. Through a happy use of example and diagram, the author manages to translate his reader into the laboratory where he can see for himself, and compare, these various methods.

The final two chapters deal with the results of measurements of nuclear moments. The first of these includes a table of all nuclear moments determined up to 1952 and a brief discussion of shielding corrections. The second was added at a later date to the original version of the book, which was published as part of Vol. 1 of "Experimental Nuclear Physics", edited by E. Segrè. This deals exclusively with the many exciting applications of these techniques to chemistry and the physics of the solid and liquid states. It would be hard to find a more brilliant refutation of those who bewail the imagined fragmentation of science than this final chapter.

One thing only tends to mar an otherwise delightful presentation, namely, the hesitant way in which concepts are introduced in the early part of the book, sometimes very fully defined and sometimes completely undefined. Thus, for example, the vector J is introduced on p. 4, but is nowhere defined as being the resultant angular momentum of the extra-nuclear electrons. Similarly, on p. 29 a selection rule for the emission and absorption of radiation is introduced without a word of explanation, although many less difficult concepts are explained with great elaboration.

Notwithstanding this criticism, Prof. Ramsey's book will remain for many years as a standard reference work for those who wish to refresh their minds on some aspect or other of the measurement of nuclear moments and their applications, and in this respect the long list of references will be invaluable. The printers and binders have done an excellent job.

B. H. FLOWERS

COLOUR TELEVISION

An Introduction to Colour Television

By G. G. Gouriet. Pp. 72. (London: Norman Price (Publishers), Ltd., 1955. Published for the Television Society.) 8*s*. 6*d*. net.

THIS book is based on two lectures delivered to the Television Society in 1954 by G. G. Gouriet, who is on the research staff of the British Broadcasting Corporation. The first part gives an elementary introduction to tricolour analysis and synthesis, leading up to the proposition that, since three variables are needed to specify a colour sensation, the basic problem is the relatively simple one of conveying three pieces of information simultaneously. While the principle was demonstrated as long ago as 1928 by J. L. Baird, and made into a workable field-sequential system in the United States, the practical difficulties of fitting it into the existing framework of broadcasting are considerable.

The second part of the book explains the system devised by the National Television System Committee, which is 'compatible' (that is, able to give an ordinary picture with receivers not adapted for colour), and can operate within the necessarily restricted bandwidth limits. This requires two signals on two carrier waves, one of which, the luminance signal, provides the compatible picture. The other carries two colour-difference signals corresponding to co-ordinates on the chromaticity diagram, the double task being effected by making the two independent modulations 90° out of phase with one another. For this purpose the axes of the chromaticity diagram are shifted, so that instead of working in terms of primaries one signal operates along the orange–cyan line of the diagram and the other along the green–magenta line.

After explaining the principles adopted by the National Television System Committee, Mr. Gouriet describes briefly the technical details of colour analysis in the tricolour camera by means of dichroic mirrors, and various means of colour synthesis at the receiving end. These include the three-tube method using dichroic mirrors, the shadow-mask system with a tricolour phosphor mosaic, and the Lawrence tube which is effectively a linear shadow-mask device. Finally, mention is made of the Valensi system, in which colour discrimination comparable with that of the eye is achieved (possibly more simply for transmission purposes) by treating the chromaticity diagram as a finite number of colour patches instead of a continuum.

The book is admirably illustrated in colour, and is very reasonably priced. It leaves one wishing one could have heard the original lectures.

DYESTUFFS CHEMISTRY

The Chemistry of Synthetic Dyes and Pigments

Edited by H. A. Lubs. (American Chemical Society Monograph Series—No. 127.) Pp. xiv+734. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1955.) 148*s*. net.

ACCORDING to the publisher's notice on the dust cover, "Here is without question the most authoritative work ever published on the subject of synthetic dyes". It should be authoritative in that it has been compiled by a formidable band of experts in the Du Pont Co., but whether it is the most authoritative is open to question. This is not an easy book to review; in fact, on a first cursory examination, the British reader is liable to form the opinion that something important is missing. It is an American book written primarily from an American point of view, which is not always quite identical with the British or European. There is no internationally agreed nomenclature for dyestuffs and intermediates; that used in America is not precisely the same as that used in Britain or in Germany, and the non-American reader must keep this point clearly in mind. The book has its shortcomings, particularly as a text-book suitable for students. For example, the historical development of the subject, as displayed in the various chapters, each dealing with a specific class of dyestuffs, is of necessity very scanty and may be misleading.

It is not always easy to follow the reasons for the development of a particular line of invention or to get a clear picture of how the chemistry of the subject developed. So much detailed information is given in such a concise form that some chapters tend to become not much more than a catalogue of the dyestuffs under discussion, with the briefest descriptions of how each is made. The literature citations, which are plentiful, may also give a false impression. Recent patent specifications with a tendency sometimes, but not always, to refer to the United States specifications rather than the original, and references to BIOS and FIAT reports predominate; thus the reader is referred mainly to very objectively written recipes for manufacturing particular dyestuffs and intermediates, and the uninitiated reader might conclude that reading dyestuffs chemistry is rather like reading Mrs. Beaton's cookery book.

It is, however, unfair to emphasize these shortcomings because Dr. H. A. Lubs and his collaborators have aimed at presenting a really up-to-date survey of dyestuffs chemistry, as it is at the present tim within the scope of a single volume. This they hav achieved; they have produced a good book, an they are to be congratulated on their performanc As in all the monographs of the American Chemic Society, the printing of the text and the innumerabl formulæ is excellent. Why, however, do publishe of such eminence persist in making difficulties f themselves and for their readers by using irregul hexagons in the formulæ of complex polycycli compounds?

S. Coffey

A NEW SCHEME OF QUALITATIV INORGANIC ANALYSIS

Qualitative Inorganic Analysis

A New Physico-Chemical Approach. By Prof. Charlot. (Translated from the Fourth French editio by Dr. R. C. Murray.) Pp. xi+354. (London Methuen and Co., Ltd.; New York: John Wile and Sons, Inc., 1954.) 42*s*. net.

MANY teachers feel that the classical method qualitative analysis is uninteresting. It ce tainly familiarizes the student with the appearan and chemical properties of a large number of i portant substances which he might otherwise nev see, and if properly taught it can be used to illu trate many aspects of physical chemistry. The u of newer organic reagents in colour reactions suffe from the objection that the student at that stage h no idea of the structure of the reagent or what happening in the process, and the procedure empirical in the extreme. Teachers may think th analytical chemistry as taught is too little related what is done in works laboratories; but each wor has its own techniques, and the object of a course qualitative analysis should be to teach chemistry.

From time to time modified schemes of analys have appeared, and this book gives one in whic group separations are abandoned and detections a by specific reagents in solution. The first part co tains a long description of various branches of i organic and physical chemistry which are at least well described in separate treatises on those subject The methods used depend largely on *p*H and red potential control and the formation of complex co pounds. Solvent extraction is also used. The pra tical part of the book goes through a number groups of elements arranged according to the ba of the scheme. Some less common elements a included. Extensive tables of equilibrium consta and diagrams of solubility products as functions *p*H as well as redox potentials are given, and ev in the second part of the book the text is interrupt by long digressions on theory.

As an alternative to the usual method, the pr cedure described in the book is certainly worth trial. I think, however, that the average stude would be bewildered by the book. If given a su stance for identification, he would not know whe to begin. A book on qualitative analysis shou serve as a guide to such an identification and not text-book of physical or inorganic chemistry. T book should be examined by teachers of qualitati analysis; even if they do not feel disposed to ado its methods, they will find much in it which will helpful in other parts of their work.

J. R. Partington

An Introduction to the Principles of Chemistry

By Prof. L. H. Cragg and Prof. R. P. Graham. Pp. ix+740. (London: George G. Harrap and Co., Ltd., 1954.) 35*s*. net.

THIS book, by two Canadian teachers, deals with what used to be called 'theoretical chemistry' and is not a text-book of inorganic chemistry. In the preface it is truly said that students from school beginning a course in a university are disheartened if their hardly won knowledge, rudimentary and sometimes incorrect as it may be, is ignored and they are compelled to go through books containing much that they already know. The authors assume that the reader has such a knowledge, and they attempt to extend and correct it.

Among the topics dealt with are the discovery and classification of the elements, atomic and molecular structure, the kinetic theory, solutions, reaction velocity and equilibrium, electrolytes, energy changes, nuclear phenomena and trans-uranic elements, applications of nuclear science, and the use of less common elements in industry. The literary style is excellent, and the book is well illustrated. Care is taken to explain all difficult points (the section on the kinetic theory of gases is notably good in this respect), and there are good exercises and hints for further reading at the ends of the chapters.

In many places the authors attempt to inspire the young reader with a real love of science and make it clear that much remains to be done in known fields, not to mention much that may yet be quite unknown. What may be called the research spirit enlivens the whole text. This is a notably good book which every teacher of chemistry ought to see. Although very modern in content and inspiration, it frequently uses the historical approach and something is said of the personalities whose work has built up the science of chemistry. Most young students are attracted by such a treatment, as the authors well know. It can win new workers in the field, and the book openly encourages its readers to join the ranks of the discoverers. The book is very attractively produced, and its price is moderate.

Experimental Inorganic Chemistry

By Dr. W. G. Palmer. Pp. xx+578. (Cambridge: At the University Press, 1954.) 50*s*. net.

COURSES in practical inorganic chemistry have always been a problem for the teacher. Most students have done parts at school, and the severe discipline called for in quantitative inorganic analysis is apt to be irksome as compared with the rather untidy progress through a course of organic preparations.

Dr. W. G. Palmer has had the ingenious idea of combining the analysis with the preparative work, and of introducing the preparation of substances not too familiar to the students but of undoubted interest and importance. The first hundred or so pages give a concise survey of modern theory in inorganic chemistry, and the book then goes through the preparations and analyses in the order of the elements in the periodic table. A compound is first prepared and then quantitatively analysed. It is certain that this plan will enliven the subject, make it more intelligible and interesting, and give the student a better appreciation of inorganic chemistry as a whole.

At the end of each section there is a short list of literature references, which are intended to be read. The theory is extended in the introduction to each group, so that the book provides a concise text-book of inorganic chemistry as well as a practical course. Many of the exercises could be done at school, and all are suitable for university courses. Dr. Palmer's book can be strongly recommended to all concerned with teaching practical inorganic chemistry, and every teacher of the subject in school or university should have a copy.

Sunspot and Geomagnetic-Storm Data derived from Greenwich Observations 1874–1954

Compiled under the direction of Sir Harold Spencer Jones. Pp. viii+106. (London: H.M.S.O., 1955.) 25*s*. net.

FOR the past eighty years the annual volumes of the "Greenwich Magnetic and Meteorological Observations" and "Greenwich Photoheliographic Results" have served to tabulate data on geomagnetic storms and measures of sunspot areas and positions. This wealth of material has now been collected in a single volume which includes catalogues of the larger sunspots and of great and small geomagnetic storms, and tables of areas of sunspots and faculæ with detailed information on the latitude distribution of the sunspots.

A feature which will be welcomed by many workers is the adoption of the calendar month for the mean areas of sunspots and faculæ; this will go far to justify the hope of Sir Harold Spencer Jones that "this compilation . . . will be useful to those investigating solar-terrestrial relationships". Each section contains explanatory notes and references to published papers; some diagrams have also been included, among which it is interesting to find Maunder's 'butterfly' diagram, which has been brought up to date and now contains more than seven complete cycles.

Thermionic Valves 1904–1954

The First Fifty Years. Pp. iii+70. (London: Institution of Electrical Engineers, 1955.) 9*s*.; or 4*s*. to members.

A DETAILED account of the celebrations, held in November 1954, of the jubilee of the thermionic valve has already been published in *Nature* (**174**, 1076; 1954). As a record of the proceedings which took place on that occasion, the Institution of Electrical Engineers has published a most attractive book entitled "Thermionic Valves 1904–1954: The First Fifty Years". The frontispiece is a photograph of the original Fleming diode; and this is followed by an appreciation of Sir Ambrose Fleming and Dr. Lee de Forest by Captain C. F. Booth, together with a copy of both the provisional and complete specifications of British Patent No. 24850: 1904, applied for by Fleming on November 16, 1904.

The next thirty pages of the book comprise the full texts of the opening address of the Marquess of Salisbury, and the three lectures given by Prof. G. W. O. Howe, Sir Edward Appleton and Dr. J. Thomson, on the occasion of the meeting at the Institution last November. The last two lectures are well illustrated by some excellent diagrams and photographs of typical valves and circuit arrangements. The book is completed by a catalogue of 242 types of thermionic valve, with nearly fifty photographs, representative of experiment and production over the past fifty years.

All those interested in the history of the thermionic valve, and the part it has played in the development of telecommunications and electronics, will welcome this publication. R. L. S.-R.

NEW X-RAY DATA ON COALS

By L. CARTZ, R. DIAMOND and P. B. HIRSCH
Crystallographic Laboratory, Cavendish Laboratory, Cambridge

FOLLOWING a recently published investigation on vitrains[1], further work has been concentrated on three topics : (1) examination of other coal types ; (2) examination of coal extracts ; (3) study of the carbonization of coals. While the results to date are in most cases only preliminary, certain qualitative conclusions may already be drawn from them. Full details will be given later.

Examination of Other Coal Types

Coal petrologists have long recognized different petrographic constituents of coals[2] ; among these vitrinite, exinite, micrinite and fusinite are the most important. These petrographic components differ both in optical properties and chemical composition. Generally, the exinite component of a given coal has a relatively high hydrogen content and the micrinite a relatively low hydrogen content compared with that of the vitrinite. A preliminary examination has been made of a series of black durains, rich in exinite, and a series of grey durains, rich in micrinite. The work on untreated durains is difficult owing to high ash content ; however, preliminary tests carried out at the Coal Survey Laboratory, Sheffield, indicate that, at least in the case of the grey durains, the mineral matter can be removed by treatment with hydrochloric and hydrofluoric acids without appreciably altering the structure.

(*a*) *Black durains*. Fig. 1 (*a* and *b*) shows low-angle X-ray patterns from two durains of different rank. The patterns can be divided into two parts : the first consists of diffuse scattering or a band at about 20 A. at low angles, together with the 002 band (due to the stacking of the layers) at higher angles ; this part of the pattern is somewhat similar to that of vitrains of similar rank, except that the 002 band is considerably sharper, and for the low-rank durain the diffuse low-angle scattering is not as prominent as for the corresponding vitrains. This part of the pattern bears a very strong resemblance to that obtained from micrinite (see below). The second part of the pattern, and the dominant feature at low angles, is the very broad band at about 4–5 A., which does not occur for vitrains. This band occurs at the same spacing as the 'γ' band found by Blayden, Gibson and Riley[3], and it is likely that the 'γ' band was indeed due to the presence of exinite in the specimen examined by these workers. Nelson[4] has also reported the occurrence of the 'γ' band in durains but not in vitrains.

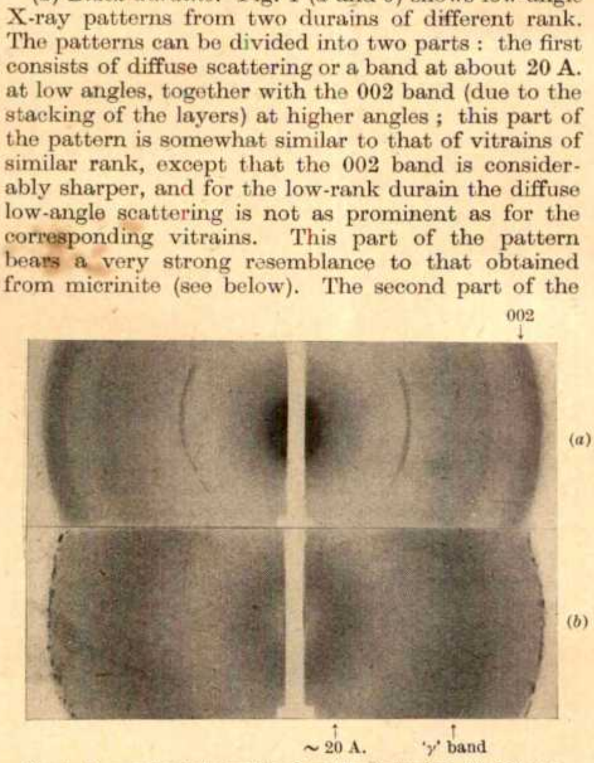

Fig. 1. Low-angle photographs of two black durains, (*a*) 82·4 per cent carbon, (*b*) 87·9 per cent carbon, showing the 002 and 'γ' bands. In the case of the higher-rank durain, there is a band at about 20 A., whereas for the lower rank, only diffuse scatter at very low angles is observed. The faint, spotty lines are due to traces of mineral impurities

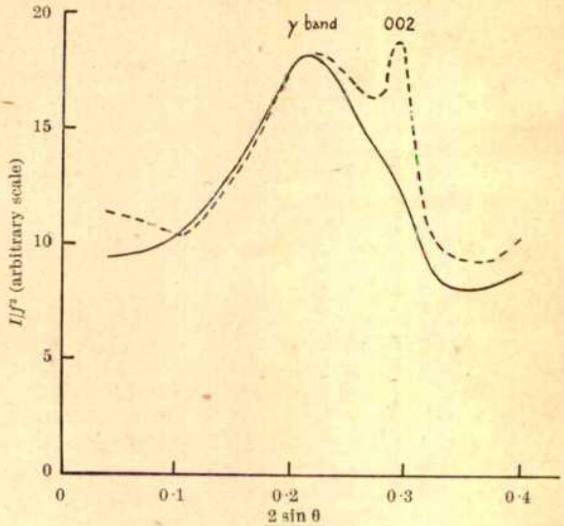

Fig. 2. Low-angle scattering from a black durain (dashes) and an exinite-rich concentrate (full-line). (f is atomic scattering factor, 2θ is angle of scatter, λ(A.) is the X-ray wave-length)

In order to decide whether the two parts of the patterns arise from different phases in the coal, an exinite-rich concentrate was prepared from one of the durains. Fig. 2 shows intensity curves as a function of $2 \sin \theta/\lambda$ (2θ is scattering angle, λ is wave-length) from the original durain and from the concentrate. It appears that in the exinite-rich concentrate both the band at about 20 A. and the 002 band are considerably reduced in intensity relative to that of the 'γ' band ; this indicates very strongly that the 'γ' band is associated with the spore material (exinite) whereas the rest of the pattern is due to another phase. Examination of slabs has shown that while the layers of the vitrain-like phase have a preferred orientation parallel to the bedding plane, this is not the case for the structure giving rise to the 'γ' band.

At high angles, only the two-dimensional diffraction bands (due to the structure within the layers) occur, and these are very similar to those obtained from vitrains.

These observations indicate in the first place that exinite, like vitrinite, consists mainly of condensed aromatic layers, although there may be small but important differences in the diameter and distortion of the layers. The 'γ' band is thought to arise from irregular packing of these layers, and the greater spacing of this band compared with that of the 002 band may perhaps be due to buckling of the layers or to the presence of more aliphatic material around

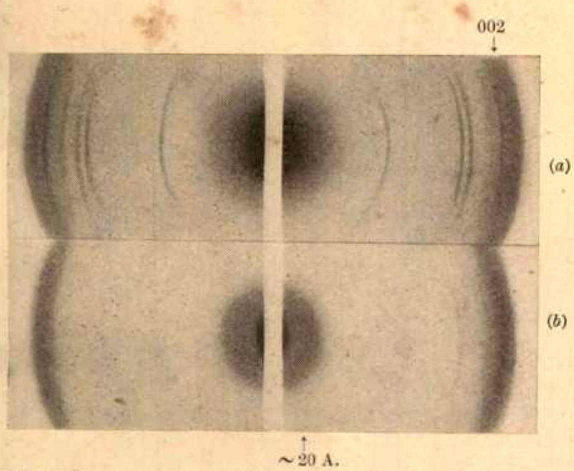

Fig. 3. Low-angle photographs of two grey durains (a) 82·3 per cent carbon, (b) 91·4 per cent carbon, showing the 002 band. In the case of the higher-rank durain, a band at about 20 A. is observed, there being only diffuse scattering for the lower-rank coal. The faint lines are due to traces of mineral impurities

he edges of the aromatic systems, which may prevent he layers from packing at a distance closer than hat possible for aliphatic chains (also about 4–5 A.). [This suggestion is in agreement with the fact that he spore material is relatively rich in aliphatic naterial (Brown, J. K., private communication).

(b) *Grey durains*. Fig. 3 shows low-angle patterns rom two grey durains of different rank. The patterns re similar to those of the black durains, except that he 'γ' band is relatively unimportant compared to he 'vitrain-type' pattern. As already mentioned for he black durains, their pattern differs mainly from hat of the vitrains in the greater sharpness of the 02 band, and in the decreased intensity of the iffuse scattering at very low angles for the low-rank oals. At high angles the pattern again consists of he usual two-dimensional bands, from which it ppears that the layers are probably of somewhat arger diameter, or more perfect, than those of the itrains. The consequent improved packing of the ayers would also account for the enhanced sharpness f the 002 band. Apart from these differences, the eries of patterns from grey durains of different rank ppear to change in a manner similar to that seen in itrains, that is, with increasing rank the diffuse ow-angle scattering decreases, and a band appears t about 20 A.

These experiments indicate that exinite and nicrinite really do represent structurally distinct hases; while the basic aromatic structure is similar, he packing of the layers in the micrinite of a grey urain is better, and in the exinite of a black durain vorse, than for the vitrains. This may be a function f the perfection of the layers or particularly of the on-aromatic edge groups. It appears that the reater the content of hydrogen and of aliphatic naterial, the more difficult it becomes for the layers o pack together.

Extracts and Residues

A series of ethylene diamine extracts from different oals has been examined. While the patterns at high angles are very similar to those of the vitrains, mportant differences occur at low angles. In the ase of the lowest-rank coal (Fig. 4a (80 per cent arbon)), a new band appears in the extract at about 12 A. (that is, $2 \sin \theta/\lambda \simeq 0\cdot08$), which is not present in the parent coal, and the low-angle scattering decreases. The same is observed with a parent coal of 78 per cent carbon. For a coal of 84 per cent carbon, a band appears in the extract at about 16 A., whereas for a coking coal of 89 per cent carbon (see Fig. 4b), which shows a strong band at about 20 A. in the original vitrain, the band moves to about 30 A. in the extract. The tentative interpretation of these results is that the extracted material is to some extent disentangled and can 'crystallize' to form the

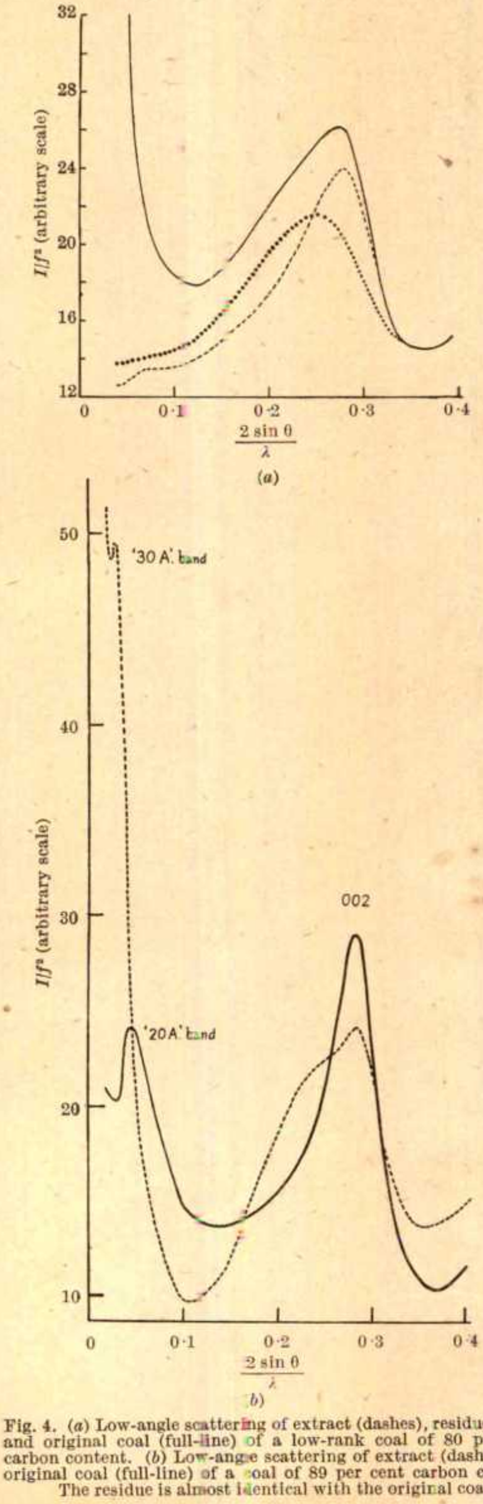

Fig. 4. (a) Low-angle scattering of extract (dashes), residue (dots) and original coal (full-line) of a low-rank coal of 80 per cent carbon content. (b) Low-angle scattering of extract (dashes) and original coal (full-line) of a coal of 89 per cent carbon content. The residue is almost identical with the original coal

same type of 'micro-pore' structure as occurs in the coking coals.

The residues left after extraction show, in the case of the low-rank coals, a marked increase in the broadening and a movement to lower angles of the 002 band and a decrease in the low-angle scattering (see Fig. 4*a*). These results indicate that, after extraction, the material left behind expands locally in the direction normal to the layers, at the same time closing some of the larger pores.

Carbonization of Coals

A caking and a coking coal have been carbonized at intervals of 100° C. from room temperature to 1,000° C. Fig. 5 shows a series of low-angle patterns obtained from the caking coal.

In the case of the caking coal, up to 400° C. the low-angle scattering decreases and the band at about 20 A. becomes more intense. Above 500° C. the 20-A. band again becomes more diffuse, until at about 700° C. it is almost completely replaced by diffuse low-angle scattering. The two-dimensional bands at high angles show that no growth of the layers occurs before about 500° C.; growth begins to be appreciable from about that temperature and probably accelerates at about 700° C. It appears, then, that up to about 500° C. the only directly observable changes are the closing of the larger pores and an improvement of the micro-pore structure; the latter, however, is at no stage as pronounced as in the coking coal. From about 300° C. these changes are accompanied by an evolution of volatile matter which proceeds at a maximum rate at about 450° C. The growth of the layers above about 500° C. is accompanied by increased diffuse low-angle scattering, suggesting a 'clustering' process leading to a wide distribution of layer diameters and a wide distribution of larger pores.

In the case of the coking coal, which shows a strong 20-A. band in the unheated state, very little change occurs up to about 500° C.; above that temperature the patterns are similar to those of the caking coal. The onset of growth also occurs at about 500° C., and detailed numerical analysis indicates that the true mean layer diameter is linear with temperature from 500° to 1,000° C., varying from 7 A. up to 14 A., with the high-temperature specimens showing some very small molecules and some larger than 20 A.

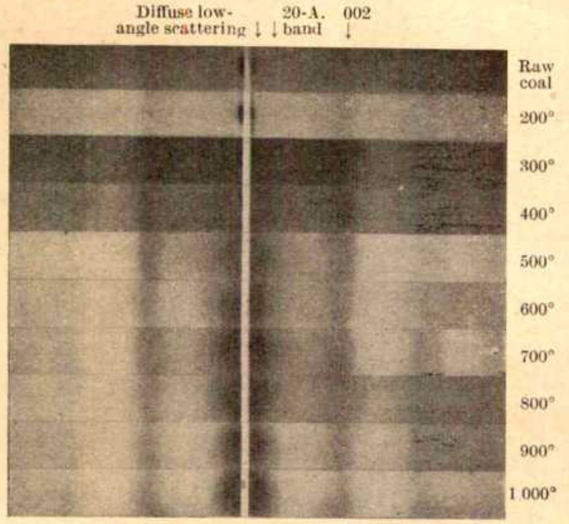

Fig. 5. Low-angle scattering from a carbonized caking coal initially of 84 per cent carbon content. Temperatures in degrees centigrade

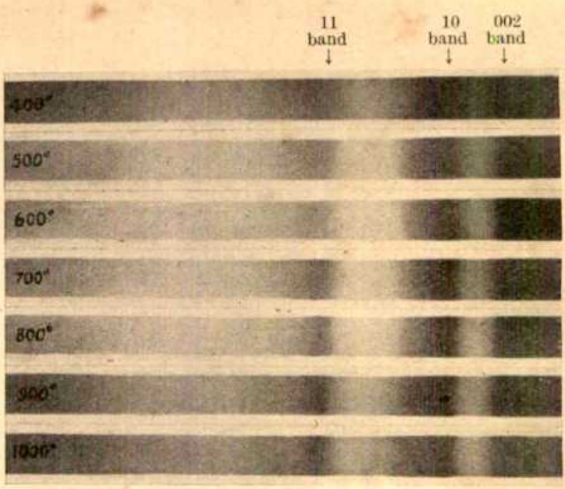

Fig. 6. High-angle photographs from a carbonized coking coal initially of 89 per cent carbon content. Temperatures in degrees centigrade

Fig. 6 shows the high-angle photographs from the coking coal, demonstrating the increase in sharpness of the 10 and 11 bands as the temperature rises beyond 500° C.

It would be premature at this stage to attempt to draw definite conclusions about the carbonization process. It is interesting to note, however, that the temperature at which growth becomes appreciable (500° C.) is in the same range as that in which a secondary reaction takes place; this reaction, on the evidence of infra-red spectroscopy[5], has been interpreted in terms of cross-linking, and is accompanied by the removal of aromatic hydrogen and hydroxyl groups. At this temperature also the concentration of 'free radicals' is a maximum[6]. The increase in layer size at higher temperatures is accompanied by a decrease of electrical resistance.

The diffraction pattern of the caking coal at 500° C. differs from that of the coking coal at 500° C. in that the band at 20 A. is not so pronounced in the former as it is in the latter. This may be correlated with the fact that the carbonized coking coal contains fewer hydroxyl groups than the caking coal[5]. The same correlation is found in the coalification series[7], where the band at 20 A. increases in intensity as the proportion of hydroxyl groups decreases.

One other feature of the low-angle photographs for the caking coal, which can be detected by eye and confirmed by photometry, is the reduction in intensity at high temperatures in the region midway between the 002 band and the direct beam. This can be interpreted as a reduction of the fraction of layers which occur singly.

A more detailed account of this work is to be published later, in which quantitative data and interpretations will be given and in which proper acknowledgment will be made of our indebtedness to a number of colleagues.

CHROMOSOMES, GENES AND MACROMOLECULAR SYSTEMS*

By Prof. FRANCIS O. SCHMITT
Biology Department, Massachusetts Institute of Technology, Cambridge, Mass.

Structure of Living Systems

It has long been supposed that organization is one of the most characteristic properties of living systems. This applies at all levels of complexity from the small metabolite molecules through the larger protein molecules, macromolecules and subcellular organelles to cells, organisms and groups of organisms. The temporally and spatially ordered coupling of energy upon the macromolecular lattices of protoplasm is at the core of most processes of cellular biology. Therefore it is most important that investigations be made of the structure and properties of this molecular machinery. Fortunately, such investigations are being actively pursued in many laboratories both from the more to the less complex (that is, studies of cellular ultra-structure by the electron microscope) and in the reverse direction (that is, crystallographic studies of the detailed structure of protein and nucleic acid macromolecules by X-ray diffraction, based upon detailed studies of the simpler single amino-acids and lower peptides).

From such studies and from physical-chemical investigations of extracted and purified materials it has been found in a number of cases (myosin, tropomyosin, paramyosin, collagen, fibrinogen, keratin) that the characteristic particle is a long thin macromolecule 15–20 A. in diameter and some hundreds or thousands of angstrom units in length. These macromolecules may be built up by adlineation of smaller units or precursors; but the full biological and chemical properties are manifested only by the larger macromolecular units. It is in these particles that the complementarity and specificity reside in so far as processes of building up and chemical interaction are concerned.

In few cases has it been possible thus far to observe the individual macromolecules directly with the electron microscope. However, under appropriate conditions, the macromolecules interact with each other to form fibrous aggregates which manifest in the electron microscope a very regular periodic cross-striated appearance. The axial period and the detailed intraperiod fine structure are characteristic of each protein. In a few cases the structure and modes of aggregation of the macromolecules have been deduced from the structure observed in the electron microscope. Collagen is one of these systems[1,2] and it will serve to illustrate what might prove to be typical of other fibrous proteins.

The macromolecular unit of collagen is a particle of dimensions about 14 × 2900 A.[3]. It is thought to be composed of three polypeptide chains in helical configuration[4-7]. The sequence of amino-acid residues in the macromolecular chains is presumably constant and specific. Therefore, the types of side-chains and their distribution along the chains are also specific. The individual tropocollagen macromolecules are themselves not banded; but when they aggregate with each other laterally to form a fibril the side-chain interaction produces regions of relative disorder or order (in the crystallographic sense) and this leads to the production of bands and interbands, respectively, in the resulting fibril, according to the suggestion of Bear[8]. Depending upon the pattern of side-chain interaction and the stability of the resulting aggregate a variety of geometrical forms might be possible. In the case of collagen at least five band patterns and several intermediate forms have been observed, and these are thought to arise by different aggregation forms of the tropocollagen macromolecules. Thus if the chains are polarized all in the same direction, 'segmental long-spacing' structures may be formed if the chain-ends are in register; if the chain-ends are staggered by a specific fraction of the macromolecular length the 640-A. type structure, characteristic of native collagen, is formed. If the macromolecular chains are running in opposite directions (antiparallel array) and chain-ends are approximately in register, the axially symmetrical 'fibrous long-spacing' structures are formed[1,2].

The very significant fact which emerges from the collagen experiments is that, although the types of aggregation possible depend upon the specific composition and molecular architecture of the tropocollagen particle, that which will occur under any particular conditions depends very sensitively upon the chemical environment (pH, ionic strength, presence of certain types of substances, etc.). The transitions from one structure to the other are freely reversible, and relatively subtle changes in the chemical environment may change the structural pattern formed on reconstitution.

Somewhat similar macromolecular interactions probably occur in the case of paramyosin reconstituted from acid[9] or near-neutral salt solutions[10].

Constitution and Properties of Chromosomes

From this background of experience regarding interaction properties of protein macromolecules certain possibilities concerning the constitution and properties of chromosomes and genes suggest themselves which, so far as I am aware, have not thus far been pointed out and which may have very far-reaching importance for genetics and for the study of differentiation and morphogenesis.

Although knowledge about the proteins and nucleic acids of chromosomes is still very limited[11,12]; it seems clear that the deoxyribonucleic acid (DNA) and possibly certain of the proteins exist as long thin macromolecules in the normal chromosome. When chromosomes (as in sperm heads) are extracted under the mildest conditions, the extracted macromolecules may be very long (30,000–40,000 A.) and thin (about 20–25 A.)[13,14]. How many species of deoxyribonucleic acid and protein macromolecules exist in the chromosome is unknown, and fractionated preparations obviously contain numerous constituents.

The giant salivary gland chromosomes of certain insects are characteristically banded when viewed in ultra-violet light or after appropriate staining. In contrast with the band patterns of fibrous proteins, those of the giant chromosomes are aperiodic rather than periodic; there is no true repeat over the extent of the chromosome (about 100μ). The positions of the various genes have been localized in the genetic (linkage) maps, with respect to these microscopically visible bands. The bands and interbands, which have highly characteristic positions, dimensions, density and staining characteristics, represent regions of relatively high or low deoxyribonucleic acid-to-protein ratios, respectively, and must be explicable in terms of a specific packing of the elongate macromolecules which compose the chromosomes.

---

* Based on a paper read before the American Philosophical Society on November 10, 1955 The detailed paper will be published in the *Proceedings of the American Philosophical Society*.

Aggregation of Macromolecules

As in the case of the submicroscopic band patterns of the fibrous proteins, the microscopically visible bands of the giant chromosomes may, for present purposes, be thought of as resulting from various types of aggregation of the constituent macromolecules, chiefly those of deoxyribonucleic acid and protein. At least five different band patterns (as well as various intermediate forms), representing as many different types of aggregation of the tropocollagen macromolecules, have been observed in systems containing only a single species of protein macromolecule, collagen. In chromosomes let it be supposed that a limited number of *species* of deoxyribonucleic acid and of protein macromolecules exist, together with histones and protamines. Various types of aggregation of the several species of deoxyribonucleic acid and protein macromolecules may occur. These include aggregation of individual species of deoxyribonucleic acid or of protein with themselves, with other species of deoxyribonucleic acid or protein (as well as with histones and protamines).

Each group of interacting macromolecules may aggregate in parallel or antiparallel array, with ends in register, out of register, or staggered according to some particular pattern of the reacting groups. In this way it would be possible, even with a relatively limited number of species of deoxyribonucleic acid and protein macromolecules, to produce specific aperiodic patterns of considerable length and having many bands, such as occur in the giant chromosomes.

Continuing the analogy, it may be suggested that, given a certain concentration of the various types of native deoxyribonucleic acid and protein macromolecules, the banded chromosomes may spontaneously form (be reconstituted) if all the factors of the chemical environment are appropriately adjusted. It would thus be unnecessary that the chromosome be reduplicated *as a whole*. Instead the constituent native macromolecules of deoxyribonucleic acid and of protein may be synthesized (presumably in the nucleus) and, assuming that their concentration has reached a certain minimal level, they will spontaneously aggregate in a manner characteristic of the native chromosome. This hypothesis would require that the cell be capable of maintaining a highly characteristic chemical environment, because only under such conditions would the various macromolecules spontaneously form the same characteristic, stable macromolecular pattern required by the cytological and genetic data.

Theory of the Gene

Still another, highly significant, possibility follows from the above view. This has to do with the gene itself. The now largely abandoned 'point determiner' theory of the gene considers that the genes occur as molecules or particles, arranged *seriatim* along the chromosome, like beads on a string. Quite possibly the inclination on the part of those examining chromosome structure in the electron microscope to pay especial attention to any particulate or bead-like structures which may be observed is another indication of the point determiner theory in modern guise. Recent experiments on the transforming factor and on bacterial viruses focus attention on the deoxyribonucleic acid macromolecule as such, and it is not incompatible with genetic data to regard highly localized regions of the deoxyribonucleic acid macromolecules, possibly even single turns of the double helix, as representing individual genes.

However, it is also possible that the chemical groupings which constitute the genes are not macromolecules or even small regions of *individual* macromolecules. Rather, the chemical groupings corresponding to genes may occur in juxtaposition on two or more adjacent macromolecules which may be the same or different species of deoxyribonucleic acid or of protein (a nucleoprotein may, in fact, be considered to be just such a lateral union between deoxyribonucleic acid and protein macromolecules linked by electrostatic or hydrogen bonds).

If this be the case, then with the same population of macromolecules of deoxyribonucleic acid and proteins, it may be possible to achieve or 'activate' a wide variety of biocatalysers depending on which species of macromolecules are in contact and on the way in which the constituent macromolecules are arrayed with respect to each other laterally, that is, in parallel or antiparallel array, with ends in register or in some kind of staggered array. Which arrays are stable under particular conditions will depend importantly on factors in the chemical environment. 'Activation' or 'inactivation' of genes might then occur merely by change in the relationship between particular macromolecules laterally without essential alteration of the constituent macromolecules themselves. Such changes might well result from changes in the chemical environment such as probably occur in processes of differentiation and morphogenesis. The resulting change in macromolecular relationship might bring into juxtaposition new chemical groupings which constitute different catalytic groups (genes); these in turn influence reactions which contribute to further steps in differentiation and development, thus constituting the feedback type of mechanism which must almost certainly be involved in the highly regulatory processes of development.

Phenomena such as position effect and pseudoalleles make the classical corpuscular picture of the gene obsolete in modern genetics. As suggested recently by Goldschmidt[15], the field of macromolecular chemistry must support and contribute to our revised notions of the gene. It is hoped that the suggestions put forward in this article will constitute a step toward bringing together biological observations and recent advances in macromolecular chemistry.

At the present time these suggestions must be regarded as purely speculative, based on properties observed experimentally in certain macromolecular systems. However, in collaboration with Dr. Herman W. Lewis, I have initiated attempts to obtain experimental evidence for at least one aspect, namely, the possibility of taking banded giant chromosomes apart into their constituent macromolecules in appropriate solutions and afterwards, by alteration of the chemical environment, to reconstitute banded structures (hopefully, though not necessarily, with a band pattern like that found in normal chromosomes). Progress in these experiments will be reported in due course.

OBITUARIES

Prof. Émile Borel

THE rapid progress of mathematical analysis in the early years of the present century was due in considerable measure to the influence of the great French school, of which Émile Borel, whose death occurred on February 3 at the age of eighty-four, was a leading figure. To high creative ability, he added expository skill and unusual powers of organization; his name is known throughout the mathematical world not only for the doctrines to which it is attached—the Heine–Borel theorem, the Borel summation process, Borel sets—but also for the vast co-operative enterprises which he directed.

The theory of sets was more warmly welcomed in France, so Cantor thought, than in its German home; certainly the volumes of Jordan's classic "Cours d'Analyse" suggested that irksome continuity restrictions could only be removed by some method more powerful than that author's theory of content. In 1898, Borel's "Leçons sur la théorie des fonctions" provided a new theory of measure, while Baire's thesis on discontinuous functions appeared in the same year; and thus the way was open for the remarkable advances of the next decade. The booklet of 1898, based on lectures given at the École Normale, was followed by similar volumes—on divergent series, integral functions, meromorphic functions—all of great value to the students of analysis. The success of the series caused its scope to be broadened, and other writers contributed, under Borel's direction, notably Baire, Lindelöf and Lebesgue. The latter's two brilliant tracts, on integration and on trigonometrical series, showed for the first time to a wide public the full precision and power of the new theory of measure and of the new integral of Lebesgue. Borel never lost interest in the series of monographs; he constantly revised his own earlier volumes and prepared new ones, the latest appearing in 1952. This bore on the constructive definition and effective calculation of numbers, a topic on which he had always held strong views—strong enough at one time to carry him into a heated controversy with Lebesgue. To-day a mathematical library without the Borel monographs is unthinkable.

Shortly after the First World War, Borel, whose chair in the Faculty of Sciences at Paris was that of probability and mathematical physics, undertook the direction of another large co-operative enterprise, the famous "Traité du calcul des probabilités", in four volumes, each of five or six parts; and this itself was supplemented by a further series of monographs on probability, one of which was Borel's own work on the mathematical theory of bridge.

Borel's considerable powers of exposition were not confined to these two famous undertakings; his writings range from school geometry to relativity, all with a sureness of touch and an almost deceptive ease of manner. His triple claim to high rank in the hierarchy of mathematicians, as creative thinker, illuminating writer and powerful organizer, will cause his name long to be remembered.

T. A. A. BROADBENT

Dr. W. L. H. Duckworth

THE death, on February 14, of Dr. W. L. H. Duckworth, at the age of eighty-five, has removed from the Cambridge scene a scholar and a teacher of great distinction. Born in Liverpool in 1870, he was educated in Birkenhead and in France before going to Jesus College, Cambridge, in 1889. His associations with this College, of which he was elected a Fellow in 1893, were to be most intimate for the remainder of his long life, and culminated in his election to the mastership in 1940. At the age of seventy-five he retired from the mastership but continued to live in Jesus College until his final illness. He was president of the Anatomical Society during 1943–45.

Duckworth had very wide interests in anatomy, teratology, primatology, anthropology, archæology and general natural history. He commenced work in the Anatomy School under Alexander Macalister shortly after obtaining a double first in the Natural Sciences Tripos. This connexion with anatomy he maintained during his clinical studies at St. Bartholomew's Hospital, London, and in 1899 a University lectureship in Cambridge in physical anthropology was established for him. In 1919 he was elected to a readership in human anatomy—a post which he held until 1940. After his retirement he maintained his interest in the collections in the Anatomy School and, in spite of physical disability, did some College and University teaching well into his ninth decade. In his maturity Duckworth's formal teaching was most impressive; complete command of the facts, great blackboard artistry, an almost pedantic accuracy in description ("it is not so much a whorl as a convolution") and an eighteenth-century aristocratic manner combined to give a character to his lectures which was much appreciated by students of all levels of ability and assiduity.

During the early years of the century, Duckworth travelled widely on archæological and anthropological expeditions, and on visits to departments of anatomy on the Continent. At the same time he pursued the study of human skulls and of recent primates with a complete devotion. Some of his many studies were summarized in his book "Morphology and Anthropology", published in 1904. This volume is still a mine of recorded facts on man and his closer relations, and it is a great pity that only the first volume of a second edition ever appeared. His work was highly individual in approach and presentation, and he inclined to put off publication in the hope that another specimen would turn up. As a result, much of his investigations was never published. His knowledge of the non-metrical features of the primate skull was unique, and his experience had given him a redoubtable sense of the appropriate in reconstructions. Consequently, he was always critical of the association of the Piltdown jaw with the cranium, and if he had been listened to in the earlier discussions on that material, several reputations in human palæontology might be a little less tarnished than they now are.

Duckworth was an insatiable collector with deep cultural and historical interests. A long life-time devoted to the gathering of material and the reading of all the related information in a number of languages gave him an impressive, almost an encyclopædic, knowledge. He was learned in half a dozen fields, and his long list of publications covers only a tithe of his life's work. He is already commemorated in Cambridge in the Laboratory of Physical Anthropology, which bears his name; this is most appropriate, for his prime interest was always the history of the human body. J. D. Boyd

Prof. S. F. Nadel

The Australian National University has suffered a great blow by the death in Canberra on January 14 of Prof. S. F. Nadel, professor of anthropology and dean of the Research School of Pacific Studies at the University. He leaves a widow and one daughter.

Siegfried Frederick Stephen Nadel was born in Vienna on April 24, 1903, the son of Dr. Maurice Nadel, a medical practitioner. Of Austrian nationality in his earlier years, he later became a naturalized British subject. He was educated first in Vienna, where he graduated D.Phil. in psychology. After a short period at Cambridge, he went with a Rockefeller fellowship to the University of London, where he took his Ph.D. in anthropology, studying under the late Prof. Bronislaw Malinowski at the London School of Economics. His first anthropological field-research was undertaken during the years 1934–37 in the Nupe Kingdom of Nigeria. From this work he published two books: "A Black Byzantium" (1942) and "Nupe Religion" (1954). The former has become a standard work in the West African field, and the latter is recognized as a very substantial contribution to the theory of primitive religion. As Government anthropologist in the Anglo-Egyptian Sudan during 1938–41, Nadel carried out research among the remote tribes of the Nuba Mountains. His book "The Nuba" (1947) is one of the most solid and extensive comparative studies in modern social anthropology; it examines the social institutions of ten different hill peoples.

During the Second World War, Nadel was appointed a political officer in Eritrea, and in 1945–46 he became deputy chief secretary in the British Military Administration in Tripolitania, with the rank of lieutenant-colonel. In 1946 he was awarded the Wellcome Medal for his anthropological writings based on his war-time experiences, and in 1950 he was given the Rivers Memorial Medal of the Royal Anthropological Institute for his field-research in Nigeria and the Sudan.

His rise in the academic field was rapid. He became lecturer in anthropology at the London School of Economics in 1946–47, reader in anthropology in the University of Durham 1948–50, and held the chair in anthropology at the Australian National University from 1950 until his death.

Nadel was one of the most significant figures in contemporary British social anthropology. His publications, which were numerous apart from his books, were noted for their theoretical stimulus as well as for the soundness of their ethnography. His general treatise, "The Foundations of Social Anthropology" (1951), was an attempt, on the whole successful, to explore the basic assumptions and methods of his science. It illustrated also his wide and informed interests in other social sciences and in philosophy. Only a week before his death he had completed a second general book, on the theory of social structure, based on lectures given in 1955 at the London School of Economics. This, too, is likely to become a standard work. Nadel was a fine scholar and a fine teacher. The Department of Anthropology and Sociology which he established and led at the Australian National University has already begun to make its mark through the quality of the work produced there. Raymond Firth

NEWS and VIEWS

Royal Society of Edinburgh: New Fellows

The following have been elected Fellows of the Royal Society of Edinburgh: Prof. D. H. R. Barton, regius professor of chemistry, University of Glasgow; Dr. J. Bell, senior lecturer in chemistry and assistant director of the chemical laboratories, University of Glasgow; the Hon. Lord Blades, senator of the College of Justice in Scotland and Lord of Session; Prof. J. H. F. Brotherston, professor of public health and social medicine, University of Edinburgh; Prof. G. M. Burnett, professor of chemistry, University of Aberdeen; Dr. J. G. Campbell, research officer (British Empire Cancer Campaign), Poultry Research Centre, Edinburgh; Dr. T. C. Carter, of the Institute of Animal Genetics, University of Edinburgh; Dr. C. B. Childs, senior lecturer in natural philosophy, University of Edinburgh; Prof. M. McG. Cooper, professor of agriculture, King's College, Newcastle upon Tyne, and dean of agriculture, University of Durham; Dr. H. K. Cowan, chief medical officer, Department of Health for Scotland; Prof. K. G. Denbigh, professor of chemical technology, University of Edinburgh; Dr. G. R. Evans, senior lecturer in natural philosophy, University of Edinburgh; Dr. D. T. Gibson, senior lecturer in charge of medical chemistry, University of Glasgow; Prof. W. G. Green, professor of mechanical engineering, Heriot-Watt College, Edinburgh; Prof. James Greig, professor of electrical engineering, King's College, University of London; Dr. D. C. Martin, assistant secretary, Royal Society of London; Dr. R. H. Millar, zoologist at the Marine Station, Millport, of the Scottish Marine Biological Association; Prof. R. Miller, professor of geography, University of Glasgow; H. N. Munro, senior lecturer in biochemistry, University of Glasgow; Dr. A. Oppenheim, professor of mathematics, University of Malaya, Singapore; Dr. Magnus Pyke, head of the Laboratory Section, Yeast Research Organization of the Distillers' Co., Ltd., Menstrie, Clackmannanshire; Dr. W. Reid, member of the National Coal Board; G. A. Stewart, formerly assistant secretary and librarian, Royal Society of Edinburgh; Prof. T. Symington, St. Mungo-Notman professor of pathology, University of Glasgow; Prof. J. W. Watson, professor of geography, University of Edinburgh.

Awards

THE following Prizes have been awarded by the Society: *Keith Prize* for 1953–55, to Prof. A. D. Peacock (Queen's College, Dundee), for his paper in the Society's *Proceedings* during the period of the award and for his contributions to entomology and cytology; *Neill Prize* for 1953–55, to Dr. Robert Osborne (Poultry Research Centre, Edinburgh), for his papers in the *Proceedings* during the period of the award and for his contributions to knowledge of the genetics of the domestic fowl.

Aeronautical Engineering at Belfast: Prof. A. V. Stephens

PROF. A. V. STEPHENS, who at present holds the chair of aeronautics in the University of Sydney, has been appointed to the newly established chair of aeronautical engineering in The Queen's University of Belfast. This chair was established in 1955 with the aid of a generous grant from Messrs. Short Brothers and Harland. The Department is situated in the new engineering and science building, and it will be operating in January 1957. Prof. Stephens graduated in 1930 from St. John's College, Cambridge. After experience with the Royal Aircraft Establishment and as research fellow and demonstrator at Cambridge, he was appointed in 1940 to the chair of aeronautics in Sydney, and he has been dean of the Faculty of Engineering there since 1949. He has built up a flourishing department in Sydney and has played a prominent part in aeronautical research in Australia. He brings to his new post a wealth of experience both in the supervision of research and in administration. His appointment will notably strengthen engineering studies in Belfast and will create another valuable link between the University and the industry of Northern Ireland.

Zoology at the Chicago Natural History Museum: Dr. K. P. Schmidt

AFTER completing thirty years on the staff of the Chicago Natural History Museum, Dr. Karl Patterson Schmidt has retired from the post of chief curator of the Department of Zoology which he has held since 1941, and the latest volume of *Fieldiana* (37 (1955), from the Museum, 10 dollars) is very fittingly offered as a tribute to him. Dr. Schmidt has led a most active life both in the Museum and in the field. A prolific but nevertheless sound writer, he is widely known in North America not only for a most imposing series of scientific papers and reports mainly on material in the Museum, but also for some popular books. In fact, to English-speaking people as a whole, he is well known for his contributions to the "Encyclopædia Britannica", as translator, with W. C. Allee, of Hesse's "Tiergeographie auf oekologische Grundlage" and as part author of the "Principles of Animal Ecology". The last two owe much to his own wide field experience in five continents. Primarily a systematist, he has rendered useful service as editor of sections of *Biological Abstracts* ("Reptiles" since its foundation in 1927 and "Amphibia" added since 1941). Vol. 37 of *Fieldiana*, in its 728 pages, illustrated by 31 plates and 144 text figures, contains twenty-six articles covering a wide range of subjects, from a comparison of Old and New World Permian Reptiles to three new species of fleas from rodents, one named after Dr. Schmidt; from beetles parasitic on mammals to bats of the genus *Vampyrops*; from a discussion on the origin of the land birds of Tristan da Cunha to the ecology of fish in North Borneo. A point of interest in this great variety lies in the fact that, in a special note, twenty-seven of the authors admit their debt to Dr. Schmidt. The production of the volume is of the excellence one has learned to expect from the series. Dr. Schmidt has much work still in hand, and we wish him a happy and fruitful time in his retirement.

Meldola Medal for 1955 of the Society of Maccabæans

THE Meldola Medal of the Society of Maccabæans has been awarded for 1955 to Dr. Peter Gray, until recently of the Department of Chemical Engineering of the University of Cambridge and now lecturer in physical chemistry in the University of Leeds. The Medal is awarded each year, on the recommendation of a committee of the Royal Institute of Chemistry, to the chemist who being a British subject and less than thirty years of age, is considered to have shown the greatest promise as indicated by his or her published work. After graduating in 1946 from the University of Cambridge, Dr. Gray began research in physical chemistry at Cambridge under Dr. F. P. Bowden, at first working on the growth and decay of the transient impulsive pressures developed during impact on liquids and the application of these results to the mechanical initiation of explosion. This was followed by a study of explosions in gaseous systems, in association with Dr. A. D. Yoffe, and led to the discovery in a number of simple decomposition reactions of cool flame phenomena, known previously only in combustion. In 1951 Dr. Gray joined the then recently established Department of Chemical Engineering in Cambridge, where his previous research on explosions developed into a study of flame propagation, particularly in chemically simple systems, which afforded crucial tests of theories of laminar flame propagation. Other fields investigated jointly in the Department were extensive work on the interpretation of the reactions of dinitrogen tetroxide; a study of the combustion of hydrazine; an investigation of the structure, reactivity and thermochemistry of the inorganic azides; and work on the thermochemistry and reactions of nitrites and nitrates.

Sir George Beilby Memorial Awards for 1955

THE administrators of the Sir George Beilby Memorial Fund, representing the Institute of Metals, the Royal Institute of Chemistry and the Society of Chemical Industry, have made awards from the Fund for 1955, each of one hundred and fifty guineas, to Dr. F. D. Richardson and Dr. F. Wormwell. The awards are made to British investigators for work in such fields as fuel economy, chemical engineering and metallurgy, in which Sir George Beilby's special interests lay, and in general they are given to relatively young scientists for work over a period of years.

Dr. Richardson's award is for his work on the thermodynamic properties of high-temperature systems, with special reference to iron-smelting and steelmaking. After graduating in 1933 from University College, London, he did research there and at Princeton University and then joined the Royal Navy at the beginning of the Second World War. On demobilization in 1946 with the rank of commander, he joined the British Iron and Steel Research Association and worked on the thermodynamics of iron and steelmaking, extending his interests to the pyro-metallurgy of non-ferrous metals when he joined, in 1950, the Imperial College of Science and Technology, London, as Nuffield Fellow to establish the Nuffield Research Group in Extraction Metallurgy. The work of Dr. Richardson and his colleagues has covered solutions in iron, copper and lead and molten salts and silicates, especially the chemistry of sulphur dissolved in molten silicates as sulphide and sulphate. New measurements have been made of the activities in the iron–carbon system and of the influence of chromium on the activity coefficients of carbon and silicon in molten iron. These and other studies have been particularly important in elucidating the reaction equilibria of the blast furnace, in deoxidation and during carbide formation in cooling metal.

Dr. Wormwell, whose award is for his work on surface reactions, with special reference to the mechanism of metallic corrosion, oxidation and passivation processes, graduated in 1926 from the University of Manchester and has spent his research career to date at the Chemical Research Laboratory, Teddington, where he is now senior principal scientific officer and head of the Corrosion of Metals Group. Much of his earlier published work dealt with studies of the mechanism of metallic corrosion in salt solutions and natural water, with special reference to the influence of oxygen supply, temperature, pressure and movement, by means of accurate rate-measurements over long periods in carefully controlled conditions. He worked jointly on oxide films formed on mild steel and stainless steel at ordinary and elevated temperatures, and the development of improved methods of stripping films from the metal substrate. This has involved corrosion studies of moving specimens, high-speed-rotor and electrochemical tests of painted steel, cathodic protection, corrosion inhibitors (particularly sodium benzoate) and underground corrosion and its prevention.

Meteorology and Geographical Features of the Antarctic

The discovery by the United States Antarctic Expedition of a great trough flanked by mountains 12,000–15,000 ft. high in the Antarctic ice-cap between Victoria Land and Wilkes Land, reported by Dr. Paul Siple, of the Expedition, in *The Times* of March 6, if confirmed, will arouse particular interest in meteorological circles in Great Britain. The trough was reported as lying between a range of mountains roughly along the 160° E. meridian and another high mountain wall about 200–300 miles to the west. The floor of the trough was at 7,000–9,000 ft. above sea-level. The probable existence of such a mountainous channel in the lofty ice-covered interior of Antarctica in the sector indicated was predicted last year by Mr. H. H. Lamb, of the Meteorological Office, and Commander G. P. Britton jointly in a paper (*Geog. J.*, 349; September 1955) quoting evidence of strong topographical effects on the atmospheric circulation in the Antarctic, and had previously been suggested in more general terms by Lamb (*Met. Mag.*, 111; 1948). Peculiarities of wind flow are often explicable from the geography of the regions in which they occur, but this is believed to be the first time that the argument has been successfully used in reverse and meteorological evidence used to predict the discovery of a major geographical feature.

The meteorological evidence is also thought by Lamb (*Geog. J.*, 59; 1948) to point to the existence of a mountain range or ice-cap crest of the order of 12,000–15,000 ft. or more in height in the heart of the hitherto unvisited region of 'East Antarctica'; the suggested approximate position and alignment were in the region about 80° S., 80° E., and parallel with the 140° E. meridian. There are indications also of low-lying regions in some parts of East Antarctica (W. Schmitt, *Notos*, 193; Pretoria, 1952) sufficiently extensive for the accumulation of deep cold air masses which acquire significance in the general circulation of the atmosphere over the Southern Ocean. Meteorologists thus have a strong interest in the discovery of the main geographical features of the still unexplored parts of Antarctica.

New Out-station for the Atomic Energy Research Establishment

The Atomic Energy Authority is acquiring two built-up areas on Grove Airfield, near Wantage, as a site for a small out-station of the Atomic Energy Research Establishment, Harwell. These two areas are part of the airfield which the Air Ministry had decided to relinquish. The new out-station is mainly to provide laboratories to allow the Technological Irradiation Group to develop more rapidly. This Group, a part of the Harwell Isotope Division, was formed in June 1955 in order to assist industry in making full use of the large amounts of radioactive material which will become available from the expanding atomic energy programme. The additional laboratories at Grove are seven miles from Harwell and less than two miles from Wantage. In the choice of the new out-station preference was given to sites which had existing buildings so that the work of the new group could be advanced as rapidly as possible. The location of the Technological Irradiation Group at Grove, rather than at Harwell, will reduce the formalities for those who wish to use the irradiation facilities, and so make it easier for industry to co-operate to the full. No radioactive waste will be discharged, as any small quantities which may arise will be transferred to the main plant at Harwell for treatment and disposal. A similar system has been used by the Radiochemical Centre at Amersham, and has proved to be satisfactory in practice. Later it is proposed to transfer the Isotope School from Harwell to the new site on Grove Airfield.

Course of Nuclear Engineering at the University of Glasgow

An undergraduate course in nuclear engineering, primarily for final-year students in the mechanical and electrical branches of the Engineering Faculty, has been in operation at the University of Glasgow since the beginning of the present session. The course provides a general background of nuclear and reactor physics for students who may later take up a specialized aspect of nuclear engineering; but as the subject becomes more firmly established further developments will be made, leading to the consideration in more detail of specialized topics. In addition to the university undergraduates, the course is being attended by a number of extra-mural students from local industry in Glasgow, and it is hoped and expected that this interest and participation will increase. Of the forty hours of lectures in the course, thirty are given by a member of the Natural Philosophy Department of the University, and the last ten by a member of the Engineering Department. The first few lectures are devoted to elementary atomic and nuclear physics, with emphasis on the energy bound in atoms, molecules and nuclei and on the possibilities of the release of this energy, and then the properties of neutrons and simple treatments of neutron thermalization are considered. This leads on to reactor physics, with calculation of the critical size of a homogeneous, graphite-moderated, pure uranium-235 reactor and simplified calculations for a heterogeneous reactor using natural uranium as fuel. A short account is given of the engineering problems caused by the fact that many materials have high cross-sections of thermal-neutron absorption. Further lectures deal with problems of irradiation, damage to reactor materials, health physics, radiation shielding, isotope separation, the breeding of nuclear fuel, and the uses of radioactive isotopes in industry. In the last ten lectures problems of heat transfer from the fuel elements to the coolants are discussed, together with the conversion of this heat energy into useful power. For the practical course, only ten two-hour periods are available, and the experiments are therefore simple, being designed either to demonstrate the orders of magnitudes of the relevant physical quantities or to illustrate points of nuclear engineering practice.

Technical College Libraries in Great Britain

A MEMORANDUM on libraries in colleges of technology and further education, which has been forwarded by the Council of the Library Association to the Scientific and Technical Information Committee of the Advisory Council on Scientific Policy, urges the need for a higher priority for college libraries in the expansion of technological and technical education and the allocation of more money for such libraries. Of the 555 institutions in Great Britain providing in some degree technical education, only 160 possess three hundred or more books housed in a room called a library, although this room is often used for other purposes and only is open as a library at specific times. 121 of these have some person other than a member of the teaching staff in charge, and altogether fifty-nine qualified librarians are employed in fifty-two libraries. The annual allowance for books, periodicals and equipment may vary from £50 to more than £2,000. Apart from meeting the needs of students and teaching staff for books and periodicals and providing an information service to assist students and staff in studies and research activities, a few of these libraries make useful contributions to the technical information service for industry; and the Library Association Council is convinced that the provision of adequate library services in technical colleges would make a valuable contribution to the dissemination of technical information and would also assist the training of qualified technologists.

For these reasons a statement of government policy regarding libraries for the various grades of technical colleges is urgently required to guide local education authorities and the Ministry of Education as to the development of existing libraries and the establishment of new ones. The Council also recommends that, in considering this development, due regard should be paid to co-ordinating the libraries with the services already provided by public, university and other libraries within the area served by the colleges, and all these libraries should be encouraged to co-operate in regional schemes for the provision of technical libraries, especially in subjects in which the college offers advanced courses. Special grants are needed to inaugurate and maintain libraries at a reasonable standard of efficiency, and the Council suggests that the 50 per cent subsidy on H.M. Stationery Office publications which is already enjoyed by public libraries and university colleges should be extended to all technical college libraries. National negotiation of salaries for qualified library staff by the appropriate Whitley Council is also recommended, as well as training in the use of libraries and books as part of the curriculum in all technical teacher-training colleges.

Ion-Exchange Resins for the Production of Pure Water

A LECTURE under the title "Will Ion Exchange replace the Laboratory Still?" was given to the Institute of Science Technology by Mr. W. F. Lorch (Elga Products, Ltd.) at King's College, London, on March 5. The considerable amount of power wastage in attempting to remove small amounts of impurities from large volumes of water was stressed. Ion-exchange resins, and the fact that most compounds ionize in water, gave the key to this problem. Three main methods of water treatment were outlined. The batch method, in which a quantity of mixed anion and cation resins is shaken with singly distilled water for one minute, is suitable for obtaining small amounts of very pure water. The two- or multi-column process requires flow through a cation and then an anion exchanger, or preferably a number of these in series since various equilibria are involved. Regeneration of the resins *in situ* necessitates the use of considerable quantities of rinse water. The single-column method uses a mixed bed of anion and cation resins, giving in effect a multi-stage process. With large-scale plants it is now possible to carry out regeneration *in situ*. The portable deionizer, which was demonstrated, is supplied with exchangeable cartridges of the mixed resins. Single-column exchangers can replace a distillation unit for most purposes. The cost of 'ion-exchange' water is in general much less than that of singly distilled water, while its conductivity is much lower. During the discussion it was mentioned that cartridges containing a dyed resin would soon be available, thereby enabling visual indication of exhaustion. The total solids obtained from an apparatus of this type is of the order of 2 p.p.m.

East African Agricultural and Fisheries Research Council: Report for 1954–55

THE East African Agricultural and Fisheries Research Council, which was established in 1954 as the governing body of the four East African Research Organizations, has issued its first annual report, covering the year 1954–55 (pp. 84; from the Librarian, Office of the Administrator, E.A. High

Commission, P.O. Box 601, Nairobi, Kenya; 1955; 3*s*.). Part 1 of the report gives a summarized account of the initial activities of the Council and the sequence of events leading to its formation. The details of its constitution and the Order approving its establishment are published as appendixes. Part 2 consists of reports from the four organizations themselves, namely, the East African Agriculture and Forestry, Veterinary, Fishery, and Marine Fisheries Research Organizations, respectively. They do not replace the annual scientific reports of these bodies, which will continue to be published separately. The aim is to give a general account in non-technical language of the individual problems, policies and achievements of the different organizations, and they certainly succeed in conveying the impression of well-planned research over a vast field. The agriculture and forestry report perhaps deserves special mention, for it reviews the work of the past seven and a half years, and in spite of the inevitable difficulties of a developmental phase, much has already been accomplished. The veterinary report provides an insight into the magnitude and variety of the problems confronting the livestock industry in East Africa, and the policy here will be to concentrate on relatively few, long-term and essentially East African problems. The establishment of the whole of this Organization at the new headquarters will simplify the necessary team-work. The fishery and marine fisheries reports are mainly concerned with fundamental investigations regarding the occurrence, life-cycles and feeding habits of freshwater and sea fish, together with complementary biological and hydrographic studies of their environment. Only on the basis of such knowledge can sound, economic fishery industries be built up.

Electronic Recording Machine for Financial Accounting

THE October issue (7, No. 9; 1955) of *Research for Industry*, the news bulletin of the Stanford Research Institute, Menlo Park, Calif., is devoted to a description of ERMA (Electronic Recording Machine, Accounting) which has been developed in the Institute's Computer and Control Systems Laboratories for the Bank of America. The machine credits individual accounts with deposits, debits withdrawals, remembers details of all transactions, maintains correct balances, prevents overdrawing of accounts, and sorts cheques. The electronic book-keeper has five input keyboards and two magnetic drums for recording up to thirty-two thousand accounts. Each cheque is identified by 'reading' information in coded-bars printed in magnetic ink on the back of the cheque. Detailed account information is stored on magnetic tapes, and monthly account statements are prepared from this information by a high-speed printer. ERMA contains 34,000 diodes and 8,000 other valves, weighs about 25 tons, uses 80 kW. of electricity and is cooled by an air-conditioning system. The first machine is to be moved to San Jose early this year to handle accounts in that area, and the Bank of America will need about thirty-seven machines to serve its branch banks in California.

New Permanent-Magnet Materials

THREE new commercial permanent-magnet materials, which are modified forms of 'Columax' and are known respectively as 'Alcomax II *S.C.*', 'III *S.C.*' and 'IV *S.D.*', are now being made by member firms of the Permanent Magnet Association (301 Glossop Road, Sheffield 10). The performances of these new materials are intermediate between those of 'Alcomax' and 'Columax', although precise specifications are not given; the development of the crystal structure is limited to certain shapes and sizes, plain solid cylinders of diameter greater than 19 mm., with length somewhat less than the diameter, being most effective. The *B*—*H* curves show considerable improvement in remanent induction, coercivity and fullness factor over those of normal 'Alcomax III'. The new materials are likely to be particularly useful to manufacturers of loud-speakers.

Auxin Transport in Woody Shoots

ALTHOUGH the polar transport of natural auxin has now been confirmed for many herbaceous and woody species of plants, the rate at which it takes place has so far only been examined directly in the coleoptile of *Avena* and in the gynophore of *Arachis hypogaea*. F. G. Gregory and C. R. Hancock (*Ann. Bot.*, N.S., 19, 76, 451; 1955) have now described a method for the estimation of the rate of movement and the quantity transported of the natural growth hormone in standard isolated segments of apple shoots. During controlled storage, diffusible auxin is collected, and later by dividing the standard length of stem into small sections the location of the auxin front is determined, from which the rate of transport is deduced. Temperature markedly affects both rate of transport and amount of auxin transported, a maximum occurring at 27–30° C., followed by a rapid fall to zero. The total diffusible auxin in a given length of stem is not affected by storage temperatures below 30° C., but falls to zero at 42° C. The rate of transport and amount transported are proportional to the oxygen tension over the range 0–5 per cent oxygen, and there is some evidence for destruction of auxin in tensions below 2 per cent.

International Association of Agricultural Librarians and Documentalists: *Quarterly Bulletin*

THE International Association of Agricultural Librarians and Documentalists was founded in 1955 to promote "internationally and nationally, agricultural library science and documentation, as well as the professional interests of agricultural librarians and documentalists". The interests of the members cover a wide field, as the term agriculture includes forestry, agricultural engineering, veterinary sciences, food and nutrition, etc. As a start, five working committees have been set up to deal, respectively, with the publication of a news bulletin, bibliography, professional problems, exchange of material and classification. The first number of the *Quarterly Bulletin* has now appeared, under the editorship of Mr. D. H. Boalch (Rothamsted Experimental Station, Harpenden), with the help of some twenty correspondents from various countries. It contains lists of new periodicals and reference books, and notices of forthcoming publications and congresses. Offers and requests for exchange and information regarding current professional literature naturally also find a place in a periodical of this type. The *Bulletin* is free to members of the Association only, the annual subscription for institutions, libraries, etc., being 50 Swiss francs or its equivalent, and for private individuals 10 francs. Inquiries regarding subscriptions should be addressed to the treasurer, Mr. T. P. Loosjes, Twentse Bank, Wageningen, Netherlands.

Low-Temperature Crystallography: Conference in Oxford

A CONFERENCE on low-temperature crystallography, organized jointly by the X-Ray Analysis Group of the Institute of Physics and the Low Temperature Group of the Physical Society, will be held in the Clarendon Laboratory, Oxford, during April 12–13. On the first day two sessions will be held on the following topics: physical problems in low-temperature crystallography (chairman, Dr. K. A. G. Mendelssohn), and X-ray methods and measurements at low temperatures (chairman, Prof. C. S. Barrett). The third, and last, session on April 13 will be devoted to a mixture of topics (chairman, H. P. Rooksby). On April 11, prior to the conference, the X-Ray Analysis Group will hold its annual general meeting, followed by a general discussion on the collection and classification of crystallographic data for determinative and reference purposes. The meetings are open to all interested, a fee of one guinea being charged to those who are not members of the Institute of Physics or the Physical Society. Registration forms and further information can be obtained from the Deputy Secretary, Institute of Physics, 47 Belgrave Square, London, S.W.1.

Discontinuance of the Physical Society's Reprint Scheme

DURING the past three years the Physical Society has run a reprint scheme whereby members and subscribers could purchase reprints of individual papers published in the Society's *Proceedings*. A survey conducted at the end of the three years has shown, however, that only about 5 per cent of the members have utilized the service and that the scheme has proved very costly, of the order of £600 a year compared with about £200 income from the sale of reprints. Accordingly, the Society has regretfully decided to discontinue the scheme as from the beginning of this year and the publication of Abstracts Bulletin No. 38.

Announcements

THE following elections have been made in the Paris Academy of Sciences: Prof. C. Bressou, director of the National Veterinary School of Alfort, to be a member of the Rural Economy Section in succession to the late Prof. M. Javillier; and Prof. F. van den Dungen, professor of analytical mechanics in the University of Brussels, to be *correspondant* for the Mechanics Section in succession to Prof. T. von Kármán, recently elected a foreign associate of the Academy.

THE Institution of British Agricultural Engineers is again offering two scholarships to candidates who are eligible for taking the final examination in 1957 for the National Diploma in Agricultural Engineering. The awards are the Farm Mechanization Scholarship (£100) of the Temple Press, Ltd., and the Dunlop Rubber Co., Ltd., Scholarship (£250), which is for a university graduate wishing to obtain the Diploma as a specialist qualification. Application forms, to be returned by May 1, and further information can be obtained from the Secretary of the Institution at 6 Buckingham Gate, London, S.W.1.

THE Society for Psychical Research is offering a prize of fifty pounds for an essay of less than 3,000 words on one of the following topics: (*a*) the best programme of research for the first one hundred hours of work with the next successful card-guessing subject discovered; the design should be supported by argument; (*b*) the best discussion of the logical and/or scientific implications of precognition, assuming this to be established statistically from the work of card-guessing subjects. Entries should be submitted under a pseudonym, and should be sent not later than October 1, 1956, to the Secretary, Society for Psychical Research, 31 Tavistock Square, London, W.C.1.

AWARDS are being offered from the Life Insurance Medical Research Fund of Australia and New Zealand, and as in previous years these will consist of grants-in-aid to non-profit institutions conducting medical research, fundamental or clinical, and research fellowships to medical graduates or those with equivalent scientific training for full-time research in problems broadly related to cardiovascular function and disease. The grants-in-aid are designed to cover all the financial requirements of a particular line of research and are usually £1,000–£3,000 a year for one to three years. The research fellowships may be taken up in Australia and New Zealand (£1,800–£2,000) for one year initially, or may be travelling fellowships for two years abroad and a third year in Australia or New Zealand (£2,000–£2,250 a year). Application forms for the awards, to be returned by July 1, and further information can be obtained from Dr. John H. Halliday, Medical Director, Life Insurance Medical Research Fund of Australia and New Zealand, 87 Pitt Street, Sydney, N.S.W.

THE Royal Society of Medicine, Section of Experimental Medicine and Therapeutics, is arranging a symposium on "Anti-tumour Agents", to be held in the rooms of the Society on May 7. Two groups of anti-tumour drugs will be discussed, namely, cytostatic agents (such as the nitrogen mustards) and antimetabolites, from the point of view of their physico-chemical properties, metabolic reactions and anti-tumour activity for both experimental and human cancers. Further information can be obtained from Dr. T. M. Chalmers, The Middlesex Hospital, London, W.1.

A SYMPOSIUM on "Corrosion Prevention in Packaging and Storage", organized by the Corrosion Group and the Birmingham and Midland Section of the Society of Chemical Industry, will be held during April 11–12 in the Chemistry Lecture Theatre of the University of Birmingham. Owing to the printing-trade dispute, it will be impossible to provide preprints of the papers; but summaries of all the papers and, where possible, complete copies of some of them will be sent to those registering for the symposium. Non-members of the Society can participate on payment of a fee of one guinea. Registration forms, to be returned by April 3, and further information can be obtained from the Assistant Secretary, Society of Chemical Industry, 56 Victoria Street, London, S.W.1.

BEGINNING this year, the *Physical Review* will no longer reprint the programmes and abstracts of papers contained in the *Bulletin of the American Physical Society*. The *Bulletin* will be published as a separate journal eight times a year and will appear previous to each meeting of the Society, so as to contain the detailed programme and abstracts of all papers to be presented at the meeting. Abstracts that appear in the *Bulletin* will not necessarily be published in the *Physical Review* or in the Society's other publications.

SOUTH AFRICAN COUNCIL FOR SCIENTIFIC AND INDUSTRIAL RESEARCH

REPORT FOR 1954

THE ninth annual report of the South African Council for Scientific and Industrial Research, covering the year ended October 4, 1954*, is, as usual, bilingual but now printed in double column. The research unit set up last year within the National Chemical Research Laboratory to deal with the needs of the Department of Nutrition has now been given independent status, and the number of major national laboratories directly controlled by the Council is now six. The Council's staff exceeds seven hundred, including 158 research scientists; but reference is made to the acute shortage of experienced scientists and engineers, particularly at the management-level, both in government technical departments and in industry. Postgraduate bursaries were awarded to sixty men and women during the year to enable them to extend their research experience, and also sixteen senior bursaries to research workers in universities and scientific institutions. An increasing proportion of the Council's operating expenses is now being met from funds other than Parliamentary appropriations, while, of the £90,000 now available annually to the five industrial research institutes subsidized by the Council, more than half is received from the industries concerned. Two new medical research units were formed during the year—for dental and for heart research, respectively, the latter being chiefly on investigation of myocardial infarction and coronary arteries. At the end of the report are a list of research bursaries and assistantships awarded during the year and also a list of publications by the Council and its staff or bursars.

In the National Chemical Research Laboratory, where a shortage of technical assistants in relation to research staff severely handicaps most divisions of the work and more experienced staff for process development is also needed, studies of South African clays have continued and further fundamental data were obtained on the electrode potentials of chromium and iron in acid solution in the presence of a mercury electrode. A fundamental study of the mechanism of autoxidation of branched-chain hydrocarbons has been initiated, and the conditions established under which pure 5-methylnonane autoxidizes without extensive gross degradation. The Laboratory is also examining the catalysts to be used in the Fischer–Tropsch process reactors and the products obtained with them. Considerable progress has been made in the desalting of brackish waters containing up to 10,000 p.p.m. of dissolved salts by electro-dialysis through ion-exchange membranes, and a pilot plant with a capacity of about 250 gallons per hour when desalting from 3,000 to 1,000 p.p.m. of sodium chloride has been operated day and night for several months to obtain design data for large-scale apparatus for gold mines in the Orange Free State to deal with brackish water. Problems involved in the purification of sewage effluents for re-use have again received priority, and operation of an experimental solar distillation unit has indicated that a unit of only 32 sq. ft. pan area is sufficient to supply drinking water for a normal household in places where only saline water is available.

Work on wool and marine oils has continued vigorously, and the optical configuration of wool wax and brain α-hydroxy acids was established by the synthesis of a series of Ls-α-hydroxy acids from Ls-malic acid. Continued study of sugar-cane cuticle wax has indicated that the main constituents are long-chain alcohols, and in view of the growing production of sisal in the Union the cuticular and wax coatings of the leaves of an *Agave* species have been studied. Fundamental structural studies are being made on the agar from *Gracilaria confervoides*; the mechanism of polymerization of certain natural fats has been further studied and the structure of methyl linoleate dimer investigated by a dehydrogenation–oxidation procedure. In the field of nutrition much attention is being given to the production of fish flour in a form suitable for enriching bread, and to its nutritional evaluation. Investigation of pentachlorophenol and other substances as inhibitors of corrosion of concrete by sulphuric acid - producing bacteria indicated that use of bactericidal cements is unlikely to prevent corrosion of concrete sewers in warm climates and that the solution must be sought in designing the sewer so as to prevent the build-up of hydrogen sulphide concentrations. The surface diffusion of adsorbed molecules has been further investigated and also the uptake of the systemic insecticide, OO′-diethyl *o*-ethylmercaptoethyl thiophosphate, from the point of view of its possible toxicity for human consumption.

The National Physical Laboratory is also experiencing difficulties in recruiting staff, particularly nuclear physicists and biophysicists, from abroad. Satisfactory progress is reported, however, with the erection of the cyclotron, which should have been complete by December 1955. Assistance is being rendered on an increasing scale to the Geological Unit of the Atomic Energy Board. A new method, based on an exchange reaction using radioactive iodine as tracer element, is being investigated for determining thyroid hormone in the blood, and the first phase of a study of hookworm infestation with iron-59 as tracer has been concluded. Progress is reported in the construction of a highly sensitive mass-spectrometer for the analysis of age of minerals with low uranium content, and electron-microscope observations on grain boundaries, sub-grain boundaries and slip traces on aluminium–copper alloys have provided direct evidence of the presence of dislocations. X-ray diffraction studies show that nickel, cobalt and zinc acetates have normal structures unrelated to those determined for cupric and chromous acetates. A curved crystal monochromator has been designed and built for the study of plastic deformation in metals, and a photometric method has been developed for the determination of sodium, potassium and calcium and also methods for determining the trace elements cobalt, molybdenum, zinc, lead, vanadium, chromium, nickel and sulphur. Further work has been done towards the establishment of primary temperature standards, and a new building for acoustic research completed and occupied. Electronic circuits for a direct-reading spectrograph have been designed so as to eliminate the photographic plate and thus speed up spectrochemical analysis.

* South African Council for Scientific and Industrial Research, Ninth Annual Report, 1953–54. Pp. x+142. (From the Council, Pretoria, 1955.)

Considerable progress has been made in establishing facilities for research in mechanical engineering. An investigation on the influence of pre-deformation on the plastic properties of metals continued, and a fundamental investigation was commenced into the effect of interrupted loading and periodic overloading on the fatigue of metals. Considerable progress was made with the construction of apparatus for examining the use of South African coal as gas-turbine fuel and for the study of heat transfer between solid boundaries and fluids, while equipment has been designed for the study of heat transfer under condensing conditions. Facilities are also being developed for testing and calibrating instruments to measure accurately the low air-speeds which often prevail in ventilated spaces, and a study of fan design in relation to noise has been started.

The work of the Telecommunications Research Laboratory has included the measurement of radio noise-levels at 100 kc./s. with the view of assessing the effect of atmospheric radio noise on navigational aids, the study of the occurrence of precipitation static and corona effects in aircraft in flight, a survey of the effect of soil and terrain on the propagation of low-frequency radio waves in South Africa, and the study by radar of lightning discharges, while for the Department of Defence radar equipment specially suited to South African conditions is being developed. The National Building Research Institute has occupied its new Building Research Laboratory; although the move considerably interrupted laboratory work, fundamental work was carried out on foundations on expansive clay soils and on the behaviour of the hydration products of cement minerals in aggressive solutions; a brochure of house plans for the urban Bantu was prepared as well as a guide to the planning of Bantu primary schools and a paper of climatic data for use in the design of buildings in the Union.

The work of the National Institute for Personnel Research has been handicapped by a shortage of graduate staff and a labour turnover as high as 27 per cent. Considerable work continues to be done on personnel selection, although the work generally is now directed to the efficient use of personnel, including aptitude tests for native labour, field studies of the mentality of indigenous African peoples, and studies on the nature and measurement of personality and of the forensic and sociological implications of electroencephalography. Defence research included a study of methods of assessing flying proficiency and a new general screening and classification test for the Union Defence Forces. Besides collecting data on road accidents in a large passenger transport corporation, the Institute is investigating the causes of motor-cycle accidents.

The Leather Industries Research Institute records progress in its studies on the structure and molecular weight of wattle tannin fractions, the structure of the chromium complex, the theories of vegetable and chrome tannage, the physical properties of the globular proteins of hides and the shape characteristics of various South African groups of feet. Much of the work of the Fishing Industry Research Institute was again on a short-term basis, but it included attempts to discover a satisfactory objective test for freshness and to determine nutritional values and trace elements in marine products. The Sugar Milling Research Institute continued to study methods of juice clarification, and much attention was paid to the occurrence of starch in cane juice and in sugars. The Paint Industries Research Institute's examination of paint performance has indicated that the climate in Durban is exceptionally severe, and that the simpler kinds of finish do not give good results. The most notable achievement of the South African Wool Textile Research Institute has been the development of a theory of the origin of medium- and long-term irregularity in worsted yarn which permits detection of a machine that is not drawing properly and also forecasts the minimum number of drawing operations required to draw and spin a given wool top. The Bituminous Binder Research Unit has completed a preliminary investigation of photo-oxidation in the weathering of binders on the road and is attempting to establish the physical mechanism of binder failure under traffic. Medical research has included further work on the culture of amœba, the pathology of bilharziasis in experimental animals, the serological diagnosis of cercariæ, the use of the ballistocardiogram in assessing the functioning of the heart, studies in the nutrition of Bantu infants and young children, the macromolecular syndrome and the experimental physiology and metabolism of the baboon, physico-chemical studies on animal viruses, and studies on bacteriophage inhibitors and the isolation of viruses.

TECHNICAL CO-OPERATION SCHEME OF THE COLOMBO PLAN

IN June 1955 the Technical Co-operation Scheme of the Colombo Plan, the main purpose of which is to help member countries to raise the level of technical skills among agricultural, industrial and other workers, in co-operation with the technical assistance programmes of the United States and of the United Nations and its Specialized Agencies, completed its fifth year, and the report for 1954–55*, issued by the Council for Technical Co-operation in South and South-East Asia, records that all four main developments noted last year gathered momentum.

There was an increased flow of technical aid experts, trainees and equipment: 1,023 training places were provided in 1954–55, compared with 508 in 1953–54, bringing the total to 2,676, of which 440 were for training in agriculture, 428 in administration, 331 in engineering, 305 in education, 293 in medicine and health, 219 in industry and trade, 195 in transport and communications and 146 in power and fuel. Australia took 916 trainees, Great Britain 853, India 340, Canada 311 and New Zealand 226. The demand for experts, 129 of whom were provided in 1954–55 (compared with 86 in 1953–54), making a total of 392 against applications for 672, was heaviest in medicine and health (117), with transport and communications (54), engineering (51), food, agriculture and forestry (47), education (42) and industry and trade (27) following. Great Britain provided 157 experts, of whom 65 went to Ceylon, 64 to India and 23 to Pakistan; Australia 115 (35 to Malaya, 28 to Ceylon, 28 to Pakistan), Canada 59 (26 to Ceylon, 11 to Pakistan); New

Zealand 44 (14 to Pakistan, 10 to Ceylon) and India 14 (10 to Ceylon, 4 to Indonesia). Posts of professors at universities and technical institutes remain hard to fill, and recruitment of some types of engineers and technicians is difficult. More inquiries are being made about the availability of firms of consultants. As regards equipment, the trend is towards equipment for establishing or expanding training and research facilities in the region with the object of training instructors. Equipment has already been supplied, ordered or offered to the value of £1·5 million against requests for more than £2 million, including £344,000 worth of laboratory equipment for research, £927,000 of training equipment and £97,000 of equipment for food and agriculture, most of this coming from Great Britain.

The movement to create or expand and improve training centres in South and South-East Asia continued. Among many examples given in the report are the assignment by Great Britain of four medical scientists to help the new medical colleges established by the Government of India by lecturing and demonstrating for ten weeks in India new techniques in diagnosis and treatment; the library facilities given by Australia and New Zealand to the University of Malaya, Singapore; the supply to Pakistan by Britain of equipment, an engineer and three demonstrator instructors to assist the change-over from manual control to automatic telecommunications; and the training of twenty-two teachers to help organize and administer technical high schools being established by the Pakistan Government.

Mutual aid in the region also made some further progress, and greater use continues to be made of technical assistance to promote economic development and raise the standard of living. Among new projects in this field the emphasis has now shifted from measures to avoid loss from pests, weeds and disease to measures to preserve food. Australia is giving equipment to the Dairy Research Institute, Bangalore, and is also arranging a tour for milk commissioners from Bombay and West Bengal and the head of the Dairy Technology Division of the Indian Dairy Research Institute to observe the large-scale handling and manufacture of milk and milk products. The Ceylon Government is taking steps to establish a rice research organization to help the drive towards self-sufficiency in rice, and Japan is sending two leading rice physiologists to study conditions in the main rice-growing areas and submit a detailed scheme for the proposed research organization. Britain has assigned an expert to the Indian Central Cotton Committee to review cotton research at the Institute of Plant Industry, Indore, and is supplying equipment to the newly established Pakistani Institute of Cotton Research and Technology at Karachi. Under the Colombo Plan agriculture is being promoted, along with industry, by irrigation and power projects, while output is being increased by the improvement of transport and communications. Britain, for example, is training the assistant director of soils for the Central Road Research Institute, Delhi, and has sent the Deputy Chief Engineer of the B.B.C. to review installation work already carried out by Radio Pakistan and to advise on the technical aspects of the future development plans; it has also assisted the Indian Central Glass and Ceramic Institute and the Central Leather Research Institute with technical facilities. Australia is providing research equipment for the brick and tile industry of Ceylon and is training a Pakistani officer who is to be employed on wool research testing, as well as five sugar technologists for Pakistan's new sugar factories.

While more trainees were sent abroad under the Scheme in 1954–55 than in any previous year, the training was also more closely fitted to the needs of the development projects. Under the Colombo Plan, including United States assistance, the countries of the area have now sent abroad 5,701 trainees and received 1,341 experts, mostly from outside the region; with the United Nations figures, the totals are 7,159 trainees and 3,741 experts. A large measure of co-operation has now been achieved, and the co-operating governments have a better idea of what forms of assistance the respective agencies can best provide.

MAN-POWER IN THE BRITISH COAL INDUSTRY

In a lecture to the Royal Institution of Public Administration on November 28, 1955, Mr. A. H. A. Wynn, scientific member of the National Coal Board, discussed the momentum of decline of the coal industry, which continued in spite of any increase in demand. Behind a fall in production from 287 million tons in 1913 to 174 million tons in 1945, the industry's ability to produce has also fallen. Mr. Wynn did not discuss many of the factors contributing to this momentum of decline, but pointed out that because of the gradual exhaustion of reserves in each individual mine, the productive capacity of the coal industry must decline by two or three per cent each year, if there is no large-scale reconstruction and no new collieries are opened. This decline affects adversely the standards of the industry's technology, its staff structure, its world reputation and its ability to recruit staff. Mr. Wynn did not discuss these imponderable psychological and educational problems, however, but rather the creation and growth of special administrative structures, some of which would be the responsibility of scientists and engineers. These organizations, he thought, are the most hopeful means of reversing the decline. He suggested that they fall under four headings: exploration, or the survey of natural resources; capital investment; the improvement of methods of production, primarily by promoting technological progress; and research and development, directed to increasing the commercial value of the industry's products. All are closely related; but only the first is peculiar to an extractive industry, and the inadequacy of our knowledge of coal resources is a factor in the momentum of decline that has delayed the reconstruction of the industry. The Board has also had to establish from slender resources the Planning Branch of the Production Department responsible for the large-scale reconstruction of old mines and the development of new ones, and its task has been made more difficult by the scarcity of suitable staff and the urgent demands for more coal.

Before 1947, the resources of the industry of Britain for promoting technological development were few; but the industry was profoundly dependent on heavy labour. A Mechanization Branch of the Production Department was established in 1947, supported by an Engineering Branch, and recently the Board has established a Central Engineering Establishment, near Burton-upon-Trent, for pursuing the development of new machines and providing guidance to manufacturers; and a Mining Research Establishment was set up at Isleworth in 1952. The Safety in Mines Research Establishment of the Ministry of Fuel and Power is still the largest mining research establishment in Britain, and the National Coal Board has inherited very few men experienced in mining research. In the post-war man-power situation, the Board has found difficulty in recruiting the scientific and technical staff it needs, and this is the main limit on the Board's expansion plans. Mr. Wynn emphasized that production depends on the outcome of a race between increased mechanization and falling man-power in the mines. Two other organizations, however, have also been established which can do much to improve productivity. The Scientific Department has established a Field Investigation Group, analogous to the operational research teams of the Service departments, and the Production Department has set up a Method Study Branch. These establishments are in close touch and will play a big part in reducing man-power requirements.

SOCIAL PROBLEMS OF INDUSTRIAL DEMOCRACY

THE Department of Social Science, University of Liverpool, has published, as Occasional Papers No. 2, "Industrial Democracy: a Revaluation", by W. H. Scott (pp. 40. Liverpool: University Press, 1955; 3*s*. 6*d*.). This essay is intended to meet the needs of industrialists, trade unionists and others who wish to acquaint themselves rapidly with some of the broad conclusions resulting from systematic research and current thought on this topic. It is limited, however, primarily to problems arising at the factory- or plant-level and is essentially a stock-taking. Industrial democracy is regarded as implying the participation, to a greater or lesser extent, of those who work in industry in determining the conditions of their working lives. The review answers the question, "Is industrial democracy desirable ?" with an emphatic affirmative, and Mr. Scott also believes that industrial development has justified our faith in the efficacy of democracy to check the arbitrary use of power.

While an extension of the democratic principle at the formal policy-making level of a firm is important, its application in day-to-day executive leadership is equally vital, and these two processes are interdependent. Mr. Scott makes some constructive comments here, and on the position of the trade unions, which are of especial interest at the moment. He notes the need to develop "consultative leadership" as part of the administrative routines of a firm at every level, as an essential concomitant to more effective formal procedures at the policy-making level, pointing out that higher management must take and maintain the initiative in both these respects. He also directs attention to the presupposed attitudes of leadership and administrative ability and to the implications in respect of selection and training for such posts. Similar considerations apply to the trade unions, and if the excessively bureaucratic tendencies of some unions are to be checked, and a balance achieved between the need for a measure of centralized administration and the desirability of developing local initiative and responsibility, then similar criteria must be applied to the selection and training of full-time trade-union officials.

Just as the effective working of any new procedures within the firm calls for a capacity for consultative leadership on the part of managers, so the delegation of greater responsibility to lay-representatives by the unions, which is so essential to industrial democracy, requires appropriate attitudes on the part of officials if it is to be used creatively. Moreover, industry does not exist *in vacuo*, and Mr. Scott points out that to achieve stable and enduring changes in industry, we must also concern ourselves with developments in other institutions of our society and particularly those which are basic and most formative of personality.

FIBRE MICROSCOPY

A WELL-ATTENDED symposium and exhibition organized by the Industrial Section of the Royal Microscopical Society was held at the British Pharmaceutical Society in London on November 16, three sessions of papers being given in the lecture theatre, while an exhibition was staged in the hall. Opening the first session of papers, Dr. R. C. Faust discussed the use of the interference microscope in the examination of fibres. The degree of molecular orientation and closeness of molecular packing at different regions of an anisotropic fibre have been studied by means of multiple-beam interference with the conventional microscope and by means of two-beam interference with the Baker interference microscope. Mr. D. S. Gowers then described the study, by interferometric methods, of the adhesion between fibres. When an artificial point of contact between a fibre and a quartz plate is examined by incident illumination, Fizeau fringes give a contour map of the fibre surface. The area of contact can be determined by the intensity distribution across the central dark spot. The effect of humidity, temperature and contaminants in the fibre was discussed.

The first two papers in the second session were devoted to the methods of producing replicas for use in the electron microscope. With textile fibres it is the surface that is of main interest, and this may be studied by means of replicas of the fibres, examined under the reflexion electron microscope. The curvature of the fibre presents an added difficulty in obtaining a successful replica, and Dr. J. Dlugosz described the various methods of replication investigated to obtain a successful routine method.

A method of producing solid metal replicas of fibres, for use in the reflexion electron microscope, was then described by D. E. Bradley, who discussed the advantages of this method over that of direct examination, and Dr. K. Little considered the use of the electron microscope in conjunction with other techniques, such as X-ray diffraction, histology and chemical investigations, in the study of fibres in human connective tissues. Each method of microscopy has its advantages and its limitations. H. W. Emerton's paper, read by D. H. Page, described how, by using three methods—namely, light microscopy, reflexion electron microscopy and transmission electron microscopy—in the study of natural fibres, a more complete picture can be obtained. By means of a plastic metal replica, the same fibre can be examined by all three methods.

The third session was opened by Dr. A. E. J. Vickers with a short historical survey of the production of quartz fibres, accompanied by a demonstration. Their physical properties, and their recent use in optics for the rapid transmission of images, were discussed. H. M. Appleyard described how the causes of faults in textiles, many of which are not obvious until the fabric has been dyed and finished, can be ascertained by microscopical examination. Faults may be due to adulterant fibre in the blend or to solid matter attached to the fibres, such as pieces of skin. Identification tests include normal histological techniques or microchemical tests followed by examination under the conventional or phase-contrast microscope. The systematic study of the removal, from a variety of textile fibres, of compounds of the same type as those found in fatty dirt from worn garments was described by R. E. Wagg. He discussed the action of several different classes of detergent, builders and other additives.

The measurement of the diameter of glass fibres, either mechanically drawn or steam-blown fibres, can be carried out by means of a projection microscope, and A. Pimblett described this method, together with the techniques required to prepare mounts of cross-sections of fibres. By this method of viewing, variations in diameter and cross-sectional shape, and the bonding together of steam-blown fibres to form insulation products, are revealed. The appearance and handle of acetate fabrics are profoundly affected by the cross-sectional shape and surface of the filament. These characteristics require to remain constant in a given spinning run, and L. Krause described how, as a method of control, yarns are examined microscopically for lustre and cross-sectional shape.

At the exhibition held in conjunction with the symposium, D. E. Bradley showed electron-micrographs of various fibres examined under the reflexion microscope by means of replicas. Faults causing electrical failure in thin oriented polystyrene-film capacitors have been identified microscopically as particles of dandruff introduced by the machine operators, and H. F. Church exhibited several of these faults, together with photomicrographs illustrating their structure. Dr. M. Dempsey and Miss B. M. Haines demonstrated a melting-point apparatus, adapted for measuring microscopically the shrinkage temperature of isolated leather fibres, and H. W. Emerton, J. Watts and D. H. Page showed photo- and electron-micrographs of various paper-making fibres.

The penetration and distribution of stain in a damaged rayon fibre can determine the type of damage, and Dr. D. G. Drummond and J. E. Ford exhibited photomicrographs illustrating the different types of fibre damage. Electron-micrographs of the surface of textile fibres made by the replica technique in the transmission electron microscope were also shown. Photographs of apparatus and of Fizeau fringes around points of contact between fibres and a quartz plate were shown by D. B. Gowers, while C. F. Griffiths exhibited specimens and photomicrographs of glass fibres containing crystalline inclusions; the inclusions may originate from the raw materials, or the refractories of the furnace or devitrification of the glass itself, and they can be identified by means of the polarizing microscope or by the X-ray diffraction method.

Photomicrographs illustrating the differences between textile fibres of vegetable origin were contributed by C. J. Jarman; from the size of the cell and the number of cells to a fibre it is possible to identify the fibre. Photo- and electron-micrographs of the fibres in human connective tissues were shown by Dr. K. Little, and J. A. Mason displayed samples of 'Perspex' and polythene that had been used for insulations and were exhibiting erosion and breakdown in the form of dendritic channels formed by local stress and heating by electrical discharges. T. S. Millen and R. S. Page demonstrated the use of the electron microscope for the examination of the surface of fibres by the reflexion method.

Slides and photomicrographs were used by A. Pimblett for demonstrating the method of measuring the diameter of glass fibres, and Dr. F. Stern showed photomicrographs and X-ray diffraction patterns of coir fibre, demonstrating the special fibrillar orientation of the cellulose microfibrils. Quartz fibres and photographs illustrating the methods for producing the fibres were exhibited by Dr. A. E. J. Vickers, and R. E. Wagg and Miss Gayner Stephens showed by means of photomicrographs the effect of various detergents on fatty dirt contaminating textile fibres. C. R. Watts contributed photomicrographs illustrating various yarns and fabrics, including modern developments in bonded and coated fibres; some common faults and their causes were also shown.

Electron micrographs and stereomicrographs showing the surface characteristics and microfibrillar texture of keratin fibres were exhibited by Mr. H. J. Woods and Dr. J. Sikorski. Miss E. Frei and Prof. R. D. Preston exhibited longitudinal and transverse sections of coniferous woods 300 A. thick for study in the electron microscope; the electron-micrographs showed the fine spiral structure of the various layers of the wall.

RHEOLOGY OF PROTEINS

A SYMPOSIUM on the "Rheology of Proteins" was held in London on January 20 by the British Society of Rheology. Four papers were presented, each of which aroused considerable discussion. The chairman, Mr. A. G. Ward (British Gelatine and Glue Research Association), in his opening remarks, outlined the wide scope covered by the title of the symposium. Proteins, the mechanical properties of which play a vital part in their functioning in living organisms, include serum proteins, epidermal and connective tissue proteins, muscle proteins, many cellular proteins, mucoproteins, and mucopolysaccharides, etc. The rheological properties of certain of these also contribute to their subsequent use in meat, egg and other protein foods, in protein fibres, in gelatin and animal glue, and in other products. In the background, for all these substances, rest the two common problems of the covalently bonded structure of the protein molecules and the secondary forces—ionic, hydrogen bonding, and van der Waals interactions—which link the molecules together to form macroscopic aggregates. Only by isolating the simplest systems will it be possible to solve the many complex problems.

Dr. E. J. Ambrose (Chester Beatty Research Institute), in his paper on the formation of structure in protein solutions, was concerned with the conditions in which a two-phase system can be formed, the protein or related component being organized or ordered in the concentrated phase. The properties of a macromolecule determining its tendency to form such structures are particle size and flexibility, the latter influencing the disturbance by Brownian movement, shape, the interaction forces, and the degree of reversibility of the changes. If the interaction forces are strong, there is a greater tendency to a disordered separation of the second phase, whereas weak forces suffice to make the necessary links only when a degree of order is attained. These considerations were illustrated by the structures obtainable with *poly*-γ-benzyl-L-glutamate in chloroform solution, and with insulin. Birefringent structures show orientation to be occurring when phase separation occurs.

Primary interest is on the behaviour of the cell nucleus and its component nucleo-proteins. Whereas nucleic acid alone fails to give phase separation, nucleoprotein forms fibrous structures, showing birefringence and dichroism. The existence of different structures at different concentrations for nucleo-proteins is shown by a discontinuity in the relation between concentration and diffusion constants. No discontinuity is observed for the nucleic acid alone. The techniques and theories have been applied to the structure of chromosomes and also to the formation of the tail of the sperm during meiotic division.

In the second paper, Dr. A. Wassermann (University College, London) described his work on a viscosimetric investigation into the influence of *p*H and ionic strength on molecular shape of a structural muscle protein. Two views have been put forward concerning the actomyosin molecule, the first regarding it as a stiff rod or elongated ellipsoid of revolution and the second treating it as a flexible random coil. Use of the mixed-bed ion-exchange resin column enables actomyosin solution of very low salt content to be prepared. Alkali additions give solutions, the 'intrinsic viscosities' of which extrapolated to zero rate of shear, and to zero concentration, are a maximum in the region of *p*H 8–9. At higher *p*H, lower values are obtained. No peak is observed on the acid side. The absence of change below *p*H 4 is assumed to arise from anion binding neutralizing the charges developed. The peak is considered to arise from the stretching out of the molecule by the repulsion of negative charges present at the *p*H's concerned. Beyond a certain *p*H the concentration of counter ions becomes sufficient to reduce the forces between the charges, so that a reduction in 'intrinsic viscosity' occurs; similarly, the addition of neutral salt in sufficient amount reduces the changes in intrinsic viscosity to zero. All these observations are fully compatible with the random coil hypothesis but are inconsistent with the stiff rod theory.

In the third paper at the symposium, on some rubber-like and relaxation properties of gelatin, Mr. D. W. Jopling (Kodak, Ltd.) demonstrated that gelatin films maintained at a water content of 25–30 per cent by immersion in 85/15 alcohol/water or by exposure to high humidity show rubber-like extensibilities of up to several hundred per cent. This is best shown when the ordered arrangement, brought about by drying, has been destroyed by immersion in boiling methanol.

By cross-linking gelatin molecules with formaldehyde, measurements on the resultant film can be carried out at temperatures at which normal gelling forces are absent, for example, 60° C. Stress relaxation then follows the Maxwell relation log (stress) $= A - B$ (time), whereas at room temperature stress is proportional to log (time). It is assumed that at 25° C. the mechanism is primarily the release of secondary bonds, with a wide spectrum of relaxation times, whereas at 60° C. only primary bonds are broken. At 40° C. both processes can be observed to occur in succession. The form of the extension–tensile stress relation for gelatin cross-linked with formaldehyde at 60° C. follows the theoretical curve for an ideal rubber-like system up to extension ratios of 4 : 1. The values for the chain molecular weight between cross-links deduced from the theory appear high; the reasons for this are not clear.

The final paper, by Dr. J. Brooks and Mr. H. P. Hale (Low Temperature Research Station), on the mechanical properties of the ovomucin gel of the egg, was given by Dr. Brooks. The thick white fraction of the hen's egg consists of a gel in which a transparent phase is separated by a series of parallel bands of microscopic fibres. After the egg is laid, the volume of thick white decreases at a rate depending on the temperature. The mechanical properties of the gel have been investigated by a method originally devised by Freundlich, in which the displacement of a minute nickel particle inserted in the gel is measured microscopically. The force is applied by means of a magnetic field. For stresses of short duration, the displacements are elastic in character in both the transparent phase and the bands. The bands are anisotropic. The relative values of the rigidities are converted into absolute units by means of a series of measurements on gelatin gels. Measurements have been made on fresh eggs and on eggs stored at 25° and 0° C., and it has been found that there is a close relation between the rigidity of the thick white fraction and its volume, irrespective of the reason for the volume difference.

A. G. WARD

SOME RECENT DEVELOPMENTS IN MAGNETISM

THE Electronics Group of the Institute of Physics held an informal symposium in London during September 23–24 on "Some Recent Developments in Magnetism", at which seven papers were read and discussed. The first speaker, Dr. E. W. Gorter (Philips Laboratories Eindhoven), outlined the theory of the magnetic properties of the ferrite group of materials. They have the spinel type of structure, in which the metal ions occupy two different types of site, and the interactions between the ions are such that the total magnetic moment is roughly equal to the difference between those for the ions in the two types of site. Dr. Gorter showed why this relation might not be exact, and how various anomalous shapes of saturation/temperature curve can occur; he demonstrated a striking example, namely, a material the spontaneous magnetization of which is reversed as the temperature rises. The properties of ferrites can be used to infer the relative strengths of the interactions between ions in various configurations, and the evidence so obtained supports the theory of super-exchange.

Ferrites are insulators, some of them having resistivities of the order of 10^6 ohms, and can therefore be studied in fields alternating even at microwave frequencies, whereas any similar experiments with metals are largely prevented by the effects of eddy currents. J. Watkins (G.E.C. Research Laboratories, Wembley) described the Faraday rotation and the transverse phase-shift, two effects observed in such experiments. The latter effect is a variation in phase and attenuation for the two directions of propagation, observed when a magnetic material in a waveguide is subjected to a transverse magnetic field. The Faraday effect, observed when there is a static magnetic field along the direction of propagation, is non-reciprocal—that is, waves travelling either with or against the direction of the static field have their planes of polarization rotated in the same direction in space.

B. G. Parkin (Post Office Research Station, Dollis Hill) discussed the properties required in the magnetic cores used for the 'memory' circuits of computers and similar apparatus. These cores should have nearly rectangular hysteresis loops and must be capable of reversing their magnetization in a few microseconds in a field of about 1 oersted. The time required for reversal is governed not only by the decay of eddy currents but also by the damping of changes of alignment of electron spins. The operating conditions can be met both with ferrites and with metal tapes a few microns thick. A rectangular loop in metals may be produced by grain orientation as the result of severe cold-rolling, or by annealing in a magnetic field. In the discussion, Dr. Gorter explained the rectangular loops of ferrites as the result of one source of anisotropy outweighing all others.

Dr. R. Street described the experimental methods developed at the University of Sheffield for the measurement of spontaneous magnetization. In the interesting range near the Curie point, the magnetization is markedly dependent on field, and the problem is to find methods which allow extrapolation to zero field. There are two main techniques available: the measurement of mechanical force in a non-uniform field, and the measurement of temperature rise on the removal of an applied field. The use of photo-electric amplifiers with galvanometers has so increased the sensitivity attainable by the second method that results obtained by the two methods can now be compared. The approximations made in deducing Curie temperatures are such that the methods lead to values differing by, for example, 4 deg. C., but the existence of anomalous shapes of saturation/temperature curves has been established beyond question.

Particles of iron, if small enough, are known to be magnetized as single domains and therefore to have very high values of coercivity. This coercivity depends on the shape of the particles, being high if they are acicular, and is also high if the anisotropy of the material is large, as in manganese bismuthide or in cobalt. Dr. E. P. Wohlfarth (Imperial College of Science and Technology, London) indicated the types of formula that have been calculated for the effect of interactions between particles in an aggregate, and for several possible distributions of particle shapes. This work has applications not only to the manufacture of permanent magnets and magnetic recording tapes, but also to the study of rock magnetism. He is now extending the theory to the properties of particles which are large enough to contain a single domain-wall.

Dr. N. C. Tombs (G.E.C. Research Laboratories, Wembley) described experiments to produce iron powders showing the properties of a permanent magnet. For practical purposes, a coercivity of about 200 oersteds is needed, which cannot be obtained with spherical particles. Particles of hydrated alpha-ferric oxide are known to have acicular shapes, and with the help of a series of electron micrographs Dr. Tombs was able to demonstrate this property on a number of these powders prepared under laboratory conditions. X-ray analysis confirmed that the particles seen in the electron micrographs were in fact single crystals. If such powders could be reduced in a stream of dry hydrogen under carefully controlled conditions, without their shape and size being altered, then the resulting iron powder should exhibit useful magnetic properties. A further series of electron micrographs showed that during the reduction much of the acicularity of the particles was lost. Sufficient remained, however, to give a useful coercivity even after compacting. Although the $(BH)_{\text{max.}}$ product was much lower than the corresponding figure for barium ferrite, the ratio of B to H is so different in the two materials that each may be useful in particular applications.

Dr. G. E. Bacon (Atomic Energy Research Establishment) reviewed the rapidly expanding field of neutron-diffraction studies of magnetism. Elastic scattering of neutrons from either ferromagnetic or antiferromagnetic substances gives regular diffracted beams which are superposed on the ordinary scattering, and from which the order of the atomic magnetic moments can be inferred (though not without ambiguity unless the specimen is a single crystal). The evidence so obtained supports Néel's theory of ferrimagnetism in ferrites, and neutron diffraction is the main source of evidence for antiferromagnetism. Ordered forms of alloys such as Ni_3Fe have been detected. Inelastic scattering also occurs; in magnetic materials it disturbs the atomic magnetic moments and causes further inelastic scattering by which the disturbance can be detected. The most serious experimental difficulty is the weakness of the available 'monochromatic' beams of neutrons, the intensity of the beams used for X-ray diffraction being about 10^5 times as great. There is great scope for further experimental work, but much of it must necessarily wait until powerful sources of neutrons are more widely available in research establishments.

Each of these seven papers was followed by questions and discussion, and Dr. Gorter's contributions should be mentioned as being particularly helpful.

DAILY MAPS OF THE SUN

IN the study of solar-terrestrial relationships, obtaining solar data of a homogeneous nature over a period of years or of decades is one of the principal difficulties. Where daily observations of the Sun are required, co-operation between a number of observatories is essential if there are to be only a small number of unrepresented days. The difficulty then arises of obtaining uniform quality of original material from the different contributing observatories. Although suitable means of doing this have been available for many years in the case of solar photographs in integrated light, similar co-operation with instruments showing the features only visible in monochromatic light has in the past been hindered by difficulties in reaching agreement on the precise instrumental requirements, in maintaining the observing routine and standard of quality; and in providing suitable means for reduction and publication of material. A fresh attempt at co-operation between a number of observatories has now been started by the Fraunhofer Institut, of Freiburg-im-Breisgau, Germany, for the purpose of producing daily maps of the Sun showing photospheric and chromospheric details and coronal intensities for λ 5303.

Among the observatories contributing chromospheric data are those of Freiburg, Kodaikanal, Wendelstein, Tokyo and Sydney. The coronal data are provided from the observatories of Climax, Sacramento Peak, Pic du Midi, Kanzelhöhe and Wendelstein. Istanbul, Potsdam, Arcetri and the German and Swedish stations on Capri also contribute material. The reduction of data and production of the daily maps are carried out at Freiburg and the printing is by a half-tone process to a scale of 15 cm. to the solar diameter. Conventions are used to show the areas occupied by calcium *plages* of low, intermediate and high intensity, and the shapes of dark filaments and limb prominences are shown, all against a background of lines giving heliographic co-ordinates. Limb coronal intensities and the positions and Zurich types of the sunspot groups are shown schematically. The aim is to produce these maps at intervals of two weeks with a delay of two weeks from the date of the latest map. Only a small number of gaps are expected to occur throughout the year.

These maps will provide a series for reference which with regard to the chromosphere should be more valuable than all other similar information published elsewhere. It remains to be seen how well the standards of indicating the various phenomena fluctuate from day to day and deviate from the initial standards over long periods of time. The possibility of such variations must be kept in mind when investigating solar – terrestrial relations, and it would be interesting to know if any special safeguards have been adopted in the present instance, where quantitative assessment apparently takes no part in the stages prior to publication. It certainly seems possible to draw quantitative information from these maps in a satisfactory manner; but it is the responsibility of the person who uses the information to make sure that it is inherently suitable for his purpose. Only the considerable task of collecting the raw material and making it available has been taken for him.

P. A. WAYMAN

B.B.C. ENGINEERING MONOGRAPHS

THE *B.B.C. Quarterly*, which has been issued since April 1946, ceased publication in the autumn of 1954, and in order to provide a vehicle for the publication of technical papers of the type hitherto included in this journal, the British Broadcasting Corporation has recently issued the first four of a series of "B.B.C. Engineering Monographs", about six of which will be produced every year (annual subscription £1); each monograph will deal with a technical subject within the field of television and sound broadcasting and will describe work that has been done by the Engineering Division of the Corporation, including, where appropriate, a survey of earlier work on the same subject. The series will also contain, from time to time, selected reprints of articles by B.B.C. authors that have been published in technical journals.

The first monograph, "The Suppressed Frame System of Telerecording", by C. B. B. Wood, A. V. Lord, E. R. Rout and R. F. Vigurs, summarizes the fundamental and practical aspects of a telerecording system using standard 35 mm. film. The recording cycle consists of exposure during one whole television frame while the film is stationary in the gate, followed by pulldown of the film during the next, or suppressed, television frame. Thus the picture photographed on the film corresponds to a 202½ line structure; but with the use of spot-wobble to broaden the lines, the recording is found to give an acceptable picture when the film is re-scanned by the standard 405 lines in the telecine machine. Three photographs accompany the description of the equipment; and the results of tests have shown that the construction of an apparatus of this type using standard film-transport mechanism has been fully justified.

No. 2 in the series is a paper on "Absolute Measurements in Magnetic Recording" by E. D. Daniel and P. E. Axon, and describes work carried out in the B.B.C. Research Department to establish methods of measuring the absolute sensitivity of the component parts of the recording–reproducing system. Another contribution from the Research Department is the third monograph, that on "The Visibility of Noise in Television", by R. D. A. Maurice, M. Gilbert, G. F. Newell and J. G. Spencer. This describes a comprehensive investigation of the effect of random noise on a television picture, its dependence on the non-linearity in the relevant portions of the transmission channels and the visibility of the noise as a function of frequency. The third part of this monograph comprises four photographs illustrating the effect of noise on a television picture for four values of the signal-to-noise ratio.

The fourth monograph is entitled "The Design of a Ribbon Type Pressure-Gradient Microphone for Broadcast Transmission", by D. E. L. Shorter and H. D. Harwood. This describes work leading to the development of an improved studio microphone for both sound and vision broadcasting, with a greatly reduced weight and volume and an extension in the range of uniform frequency-response.

Summaries of recent patent applications by the B.B.C. are also included in two of the monographs, each of which is issued in a distinctive two-tone blue cover. It is likely that the series will be of interest and value to engineers engaged in broadcasting and telecommunications generally both in Great Britain and overseas.

THE METEOROLOGICAL OFFICE

ANNUAL REPORT FOR 1954–55

THE annual report for 1954–55 of the Director of the Meteorological Office* records another year of steady progress and of honest endeavour by the Office to meet the ever-increasing demands for its services. There appears to be little need for special comment regarding two of its main functions: the provision of meteorological services for civil and military aviation, for shipping, for the general public by television, radio, telephone and through the Press, for special customers such as the railways, electricity and gas undertakings, farmers, river and road engineers; and the collection, distribution and publication of meteorological data. These routine duties, which do not often reach the headlines (except when a forecast goes badly wrong on a Bank Holiday!), but which assume an ever-increasing importance in modern society, bear heavily on the Meteorological Office, which is under-staffed, poorly housed and under-financed. The total annual budget of the Office is less than £3 million—little more than the cost of a modern bomber. This is not a large sum on which to carry out its multifarious activities at home, to meet its overseas and international commitments, to develop new instruments and improved techniques and to undertake an extensive programme of research in meteorology and geophysics.

---

* Annual Report of the Director of the Meteorological Office, presented by the Meteorological Committee to the Secretary of State for Air, for the Year April 1, 1954, to March 31, 1955 (M.O. 594.) Pp. 68. (London: H.M.S.O., 1955.) 2*s.* 6*d.* net.

It is, of course, largely by the quality and scope of its research that the vitality and scientific reputation of such an organization must be judged. Considerable progress has been made during the past few years, and the present report shows that this has been maintained. There have been encouraging developments in the study of numerical forecasting with the aid of electronic computers, and it has recently been announced that the Office is to have a machine of its own. The Meteorological Research Flight has continued its investigations on the distribution of water vapour and ozone and the occurrence of clear-air turbulence at high altitudes, and into the structure and constitution of clouds. Progress was made in the measurement of solar radiation and in the development of the new radar-sonde. Some attention has also been given to the possibility of increasing rainfall by cloud-seeding, and preliminary field-trials have been started on Salisbury Plain.

The pace of all this work has necessarily been limited by the availability of personnel, and the Director stresses that the continued shortage of scientific staff and the high turnover-rate (about 20 per cent per year) of assistants are matters of some concern. The total number of scientific officers on the staff of the Office is only 155, not all of whom are actively or mainly engaged on research. More serious still, only four new officers were recruited during the year—barely enough to compensate for losses through retirement and resignation. How to attract sufficient numbers of high-quality physicists and mathematicians into a field which, after all, has great opportunities for research, is perhaps the main problem facing the Meteorological Office at the present time. One welcomes, therefore, the continued and extended co-operation between the Office and the universities, both of which have a responsibility for ensuring that Britain is not left behind in the great expansion now taking place in atmospheric physics.

B. J. Mason

PHYTOPLANKTON OF LAKE TANGANYIKA

FOR one who is not conversant with all the recent work in the biological study of lakes, there is much of interest in the volume by L. van Meel, entitled "Le Phytoplancton", one of a series of reports of the Belgian Expedition (1946–47) for the "Exploration Hydrobiologique du Lac Tanganika" (Institut Royal des Sciences Naturelles de Belgique. Bruxelles, 1954. 4, Fasc. 1. *A*, Texte (pp. 681); *B*, Atlas (pls. 76)). Likewise it will be particularly interesting to all those whose experience is limited to small temperate lakes. On the other hand, the title does not prepare the reader for the table of contents, which shows that geobotany, geochemistry and geophysics of all the central and eastern African lakes (and of nineteen in particular) fill pp. 7–250. The next two hundred and twenty-five pages are devoted to a list of the algae of these lakes, and the third section dealing with the ecology of the plankton occupies one hundred and seventeen pages, the phytoplankton of Lake Tanganyika being covered in thirty-four. This indicates that a more suitable title should have been chosen for a volume which is mainly a compilation of the available information of certain aspects of these African lakes, with the additional information collected by the Expedition about the phytoplankton of Lake Tanganyika. As a compilation, it will be a most useful book of reference to many, and the information gathered together here about any one lake will provide the basis for a fuller and more searching investigation of it. The contribution by British workers to our knowledge of these lakes is clearly brought out.

The size of Lake Tanganyika is one of its most striking characters. It is the second largest of the African lakes, with a volume approximately half that of the North Sea. It is also very deep (1,470 metres in the deepest trough), being exceeded only by Lake Baikal. These facts, together with its situation near the equator and the protection given by high land from the full force of the south winds, are some of the factors combining to preserve the stratification of the water and to reduce mixing to a minimum. It is stated to have greater thermal stability than any other lake, the variation in temperature at two hundred metres being less than 5/100 deg. throughout the year. The water is clear and well-oxygenated down to a depth of 40–100 m., depending on the place and season, but from 100–225 m. to the bottom (the equivalent of three-quarters of the volume of the lake) there is no oxygen but an abundance of sulphuretted hydrogen. This is the result of the stratification (scarcely ever disturbed at these depths) and the reason for the statement that a total 'turn-over' would have disastrous consequences. It is supposed that even a partial 'turn-over' may not take place annually.

Tanganyika is a diatom lake, and in his investigations van Meel found no new species in the phytoplankton. The new information concerns rather the geographical distribution of the algæ, chiefly at the surface. The plankton of the bays is much richer than the pelagic plankton, which is poor in species (*Oocystis*, *Nitzschia*, *Anabaena*, *Anabaenopsis* being the common genera) rather than in individuals. During the Expedition's stay, the volume of plankton, however, was poor throughout most of the year, but an increase occurred in October 1946, at the end of the dry season. The permanent stratification of the deepest layers of water would appear to be an obvious reason for the poverty of the plankton, as the author suggests; but van Meel considers the inhibiting effect of light on chlorophyll to be an added reason. This would seem to control its position in depth in the Lake rather than its quantity. A certain amount of sampling at different depths leads to no obvious conclusions. With a small amount of plankton in such a large body of water, it is possible that its distribution is uneven due to currents and micro-stratifications. One set of readings appears to show a correlation with the diurnal movement of the zooplankton; but as a result of the general consideration of the food-supply of the latter, van Meel puts forward a hypothesis that it may be provided by a bacterial flora rather than by the phytoplankton.

It is concluded that Lake Tanganyika should be classed as pseudo-eutrophic since it shows characters of both oligotrophic and eutrophic lakes. On the other hand, this unusual combination of characters might suggest the need for a revision of the classification of lakes.

This is a very lavish production, information being well displayed with the aid of a liberal supply of maps, tables and diagrams. A separate volume of seventy-six plates illustrates many species of the phytoplankton of these African lakes.

KATHLEEN M. DREW

THE PRODUCT OF THE HUMAN BLOOD GROUP *A* AND *B* GENES IN INDIVIDUALS BELONGING TO GROUP *AB*

By PROF. W. T. J. MORGAN, F.R.S., and DR. WINIFRED M. WATKINS
Lister Institute of Preventive Medicine, London, S.W.1

INTEREST in the chemical nature and serological relationships of the substances which are responsible for the differentiation of human red blood cells into well-defined groups arises from two sources: these materials are of importance in the field of immunochemistry because each possesses a distinct serological specificity, and in the field of biochemical genetics because each characteristic specificity is believed to be the result of the action of a single gene.

The only human blood-group substances for which the chemical nature is known with any degree of certainty are those which characterize the *ABO* and *Lewis* systems, since these specific materials occur in the tissue fluids and secretions in a water-soluble form. The *A* and *B* substances have been isolated in an essentially homogeneous condition and a thorough study has been made of the chemical, physical and serological properties of these materials[1]. Comparatively little work has been carried out, however, on the material showing both *A* and *B* properties which is secreted by individuals belonging to group *AB*. The question arises whether the secretions in these heterozygous individuals contain molecules which carry both *A* and *B* specific groupings, or whether they contain a mixture of molecules some of which carry *A*, and others *B*, specificity. Wiener and Karowe[2], in their development of a diagrammatic representation of human blood-group reactions, assumed that in group *AB* individuals the molecules possess dual specificity; but chemical or serological evidence for the association of both specificities with one molecular species, or for the presence of molecules with single specificity only, has been lacking.

The close chemical and physical similarity of the *A* and *B* substances means that they are not separable by the usual fractionation procedures, including electrophoresis and ultracentrifugation, and therefore an attempt has been made to obtain evidence on this question by means of serological precipitation tests. The methods employed involved the precipitation of the specific group substance in (i) an artificial mixture of *A* and *B* substances, and (ii) the material obtained from *AB* individuals, with anti-*A* or anti-*B* precipitating sera; the specific activity of the original materials, the solutions remaining after removal of the precipitates and the redissolved precipitates was determined by means of agglutination inhibition tests. It was hoped thus to separate the specific materials contained in an artificial mixture of *A* and *B* substances and to determine the behaviour of the *A*- and *B*-specific activities present in the secretions of an *AB* person.

The blood-group materials used were preparations derived from human ovarian cyst fluids[3] which had been subjected to the phenol-extraction procedure[4], or fresh saliva samples which had received no treatment other than heating in a boiling water-bath, followed by centrifugation to remove insoluble material. Anti-*A* and anti-*B* sera prepared in the rabbit were used as precipitating reagents, and some additional experiments were carried out with a purified extract of Sieva Lima beans[5], which contains powerful anti-*A* precipitins. The precipitating reagents were freed from heterologous agglutinins or precipitins before use. The concentration of *A*, *B* or *AB* substance giving suitable precipitation with the appropriate reagent was determined and 1 ml. of a solution containing this concentration of material was then mixed with 1 ml. of the precipitating reagent. The mixtures were incubated 1 hr. at 37°, followed by standing over night at 0–4°, and the precipitates were then spun down at 0°, redispersed by high-speed stirring, washed three times with ice-cold saline, and dissolved in 0·2 ml. of $N/10$ sodium hydroxide. The solution was neutralized and the volume made up to 1 ml. with saline; finally, when rabbit precipitating sera were used, the solutions were heated 10 min. in a boiling water-bath to destroy the activity of any remaining antibody. This step was unnecessary when Sieva protein was used because its specific anti-*A* properties are rapidly destroyed by treatment with dilute alkali.

The results of an experiment using a rabbit anti-*A* serum as precipitant with a mixture of *A* and *B* cyst materials and with a substance obtained from a group *AB* cyst are shown in Table 1. The agglutination inhibition tests were carried out using a twofold dilution series of the test substance and a constant amount of antibody. The inhibition is expressed as the number of tubes which failed to show agglutination. When one considers the results obtained with the artificial mixture of *A* and *B* substances, it is evident that the supernatant solution remaining after removal of the specific precipitate has lost its capacity to neutralize the agglutinating action of anti-*A* serum on *A* cells, but retains, unimpaired, its capacity to inhibit the action of anti-*B* serum on *B* cells. The results given by the redissolved precipitate from the *A* and *B* mixture support these observations; the precipitate shows *A*-inhibiting activity but is without *B*-activity. These findings demonstrate, therefore, that it is possible to separate an artificial mixture of *A* and *B* substances by the precipitation technique.

Examination of the results obtained with the *AB* cyst material, on the other hand, reveals that after removal of the precipitate the supernatant solution shows an almost complete loss of *B* activity in addition to loss of *A* activity, and the precipitate

		,, *AB* substance	6
Rabbit anti-*B* serum + *B* cells	(*a*)	Untreated	
		A + *B* mixture	5
		,, *AB* substance	5
	(*b*)	Supernatant from	
		A + *B* mixture	5
		,, *AB* substance	1
	(*c*)	Precipitate from	
		A + *B* mixture	0
		,, *AB* substance	5

possesses both *A* and *B* activities in the same ratio as in the original solution. These results are typical of those obtained with three purified *AB* cyst materials which had originated from different individuals, one native cyst substance, five different A_1B saliva samples and two A_2B saliva samples. Substitution of the Sieva Lima bean precipitant for the rabbit antibody gave essentially similar results. When rabbit anti-*B* serum was used as the precipitating reagent, the reverse picture was obtained with the *A* and *B* mixture; that is, *B* substance only was precipitated and removed from the mixture, whereas both the *A* and *B* activities were carried down in the precipitate from the *AB* cyst substance.

The evidence obtained from these experiments strongly indicates, therefore, that in the tissue fluids and secretions of secretors belonging to group *AB*, a large proportion, if not all, of the macromolecules showing blood group specificity possess both *A* and *B* properties. The fact that it has been possible to separate artificial mixtures of native *A* and *B* salivas into their serologically specific components indicates that the failure to separate the group factors in the saliva of an *AB* person is not due to the simple formation of complex aggregates when both specific substances are present. As an additional control, fresh native *A* and *B* saliva samples were incubated together at 37° for 1 hr., then heated at 100°, and examined as described above; complete separation of the specific activities was again accomplished. The implications of these findings are of importance from the point of view of any biochemical approach to the nature of the materials secreted by *AB* individuals, and also must be considered in the application of quantitative precipitation tests to these substances.

It appears, therefore, that in heterozygous *AB* individuals the *A* and *B* genes give rise to a molecular species which differs from that produced by either gene in the homozygous state, and this fact is of considerable interest in human biochemical genetics. The interaction of genes in the heterozygote has received much attention in relation to hybrid vigour in plants and animals. In man, however, only two examples of the interaction of genes at a single locus have hitherto been worked out in biochemical terms. Haldane[6] quotes the findings of Filliti-Wurmser, Aubel-Lesure and Wurmser[7], on the molecular size of β-agglutinins, as an example where the heterozygote produces a product which differs from that produced by either of the genes in the homozygous condition. These authors found that the molecular weights of the β-agglutinins in *OO*, A_1A_1 and A_1O individuals were 170,000, 300,000 and 500,000, respectively. However, there is some difference of opinion as to whether the formation of the naturally occurring isoagglutinins is under direct genetical control[8]. The second example relates to the hæmoglobins produced in individuals carrying the sickle-cell trait. Neel[9] and Beet[10] put forward the hypothesis that the sickle-cell trait and sickle-cell anæmia occur respectively in individuals heterozygous and homozygous for the same abnormal gene. This gene was afterwards shown to be responsible for the production in the homozygote of a hæmoglobin which differs in its electrophoretic mobility and solubility from that present in normal individuals, and the sickle-cell gene is believed to be an allele of that which produces normal hæmoglobin[11]. In the cells of individuals heterozygous for this condition, that is, those carrying the sickle-cell trait, both the abnormal and normal types of hæmoglobin are found to be present and to migrate independently on electrophoresis.

It is evident, therefore, that no general rule as to the influence in man of genes heterozygous at a single locus can be drawn from the examples known at present. When one considers the results of Filliti-Wurmser *et al.*[7] on the molecular weight of β-agglutinins, and the behaviour of the *AB* blood-group substance reported here, the product in the heterozygote would appear to differ in molecular nature, although not in general specificity, from the product produced by either of the genes when present in the homozygous condition; in the example of the hæmoglobin genes, on the other hand, the allele giving rise to the sickle-cell type of hæmoglobin and that producing normal hæmoglobin each gives rise to its own characteristic product in the heterozygote.

The method of approach outlined here involving the use of serological precipitation tests to determine whether more than one specificity is associated with a single molecular species is now being applied to preparations of *A*, *B* and *Lewis* substances showing *H* specificity[12]. It is hoped thus to obtain information which will help in the elucidation of the genetical relationships of the *H* character to the products of the *A*, *B* and *Lewis* genes.

We wish to thank Prof. W. C. Boyd for a gift of purified Sieva bean protein, and Drs. Glynn and Holborow for some of the anti-*A* and anti-*B* rabbit sera used in this investigation. These studies were aided by a grant from the Nuffield Trust. [Jan. 19

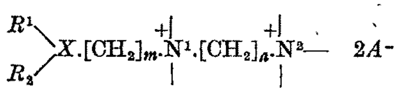
New Series of Ganglion-blocking Agents

Powerful ganglion-blocking properties have been found in the diquaternary-amino-carbinols (I), alkenes (II), -alkanes (III), -nitriles (IV), -ethers (V) and -esters (VI) :



$$\begin{matrix}R^1\\R_2\end{matrix}\!\!>X.[CH_2]_m.\overset{+|}{N}{}^1.[CH_2]_n.\overset{+|}{N}{}^2— \quad 2A^-$$

$I ; X = C(OH)CH_2$ $\quad IV ; X = C(CN)CH_2$

$II ; X = C:CH$ $\quad V ; X = CH.O$

$III ; X = CH.CH_2$ $\quad VI ; X = CH.CO.O$

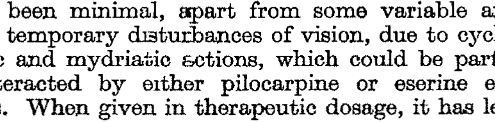
R^1 and R^2 are phenyl or *cyclo*hexyl groups in the compounds described in this communication, but preliminary results show that ganglion-blocking action also occurs when R^1 and R^2 are pyridyl or thienyl groups. $\overset{+}{N}{}^1$ and $\overset{+}{N}{}^2$ are fully substituted quaternary nitrogen atoms.

These compounds are structurally related to the large group of tertiary and quaternary amines of the benzhydrylalkyl type which has already yielded a number of clinically useful drugs. Thus, the new compounds I–III are related to the series of spasmolytics, antihistamines and analgesics which we have previously studied, for example, tricyclamol, procyclidine, triprolidine and the thiambutenes ; while series IV, V and VI are related to the methadone series of analgesics, the antihistamine diphenhydramine, and the spasmolytic 'Trasentin' respectively. The introduction of the group consisting of two quaternary nitrogen atoms linked by a short polymethylene chain, in place of the tertiary or quaternary amino-group of the known compounds, has conferred ganglion-blocking activity on all these classes of drugs and divested them of their previous types of activity. The new compounds have a structural feature in common with the methonium type of hypotensive agent, namely, two quaternary amino-centres, which in our compounds should preferably be separated by two or three methylene groups.

The pharmacological actions of a large number of these compounds have been examined in several species. The most prominent actions include lowering of blood pressure, antagonism of the hypertensive effect of intravenous doses of the ganglion-stimulating compound, N^1 : N^1-dimethyl-N^2-phenylpiperazinium iodide (DMPP), inhibition of vagal bradycardia and augmentation of the hypertensive effects of intravenous adrenaline and *l*-noradrenaline in anæsthetized cats and dogs. It is of interest that somewhat larger doses than those producing these effects have generally been required to block the effect of short periods of preganglionic stimulation on the nictitating membrane, which preparation is the one most commonly employed in the laboratory for the assessment of experimental ganglion block. However, the compounds have so far invariably prevented contractions of the nictitating membrane caused by preganglionic stimulation, but not those due to postganglionic stimulation or intravenous adrenaline. Some are powerful inhibitors of gastric secretion in pyloric-ligated rats ; in contrast to atropine-like compounds, they have been effective at doses considerably lower than those dilating the pupil. Mydriasis occurs after parenteral but not after local administration of the compounds ; their activity in this respect has so far been relatively greater in some species, for example, mice and cats, than in others, such as rats, dogs and man. They inhibit powerfully the peristaltic reflex of isolated guinea pig ileum, but not the peripheral muscarinic effects of acetylcholine on the isolated ileum or on the blood pressure of the cat. These findings indicate that the main pharmacological effects of the compounds are due to block of autonomic ganglia. The main toxic action is closely associated with neuromuscular block, which with many of the compounds has not occurred until after at least a hundred times the dose causing some ganglion blockade.

A number of relationships between structure and activity have emerged, based mainly on mydriatic action in mice but supported by other findings. As *m* has been increased from 1 to 7, activity has reached a maximum at $m = 3$ or 4 and then has declined, while duration of action has progressively increased. Toxicity in mice has slightly increased with the value of *m*, and when *n* has been increased from 2 to 6 toxicity has often increased as much as threefold. Activities have been greatest when the substituents on $\overset{+}{N}{}^1$ and $\overset{+}{N}{}^2$ have been no larger than ethyl, this also applying when $\overset{+}{N}{}^2$ formed part of a pyrrolidinium, piperidinium or morpholinium ring.

Some of these compounds are considerably more active in many laboratory tests than hexamethonium and pentolinium, and their effects last very much longer. A few have been successfully used clinically in the treatment of hypertension. These are highly effective in lowering blood pressure and relieving certain hypertensive symptoms, when given subcutaneously in doses of up to 40 mgm. or intravenously in smaller dosage ; the effects are slow in onset and persist for several hours. Like other quaternary ammonium salts, they are poorly absorbed after oral administration, the minimal effective dose by this route being about ten times the subcutaneous.



356*C*54

In these clinical trials the compound 356*C*54 has so far been one of the most promising. Subcutaneous injection of an effective dose of this drug has usually lowered the blood pressure for 7–12 hr. Side-effects have been minimal, apart from some variable and often temporary disturbances of vision, due to cycloplegic and mydriatic actions, which could be partly counteracted by either pilocarpine or eserine eye drops. When given in therapeutic dosage, it has less frequently caused recurrent postural syncope than have hexamethonium and pentolinium.

Another outstanding feature is that these drugs have not caused paralytic ileus or severe constipation, and apparently have only a slight effect on propulsion in the small intestine. However, they have powerfully inhibited gastric acid secretion and motility. This and the animal pharmacology suggest that another possible use of these compounds might be in the treatment of peptic ulceration.

Full investigation into the chemistry, pharmacology, clinical activity and use of these and related compounds is being actively pursued, and the results of these researches will be published in detail elsewhere.

Effect of Cortisone on the Blood

Nicol and Snell[1] showed that the phagocytic activity of the reticulo-endothelial system becomes depressed during the first two weeks of cortisone treatment and recovers to about the normal level during the third and fourth weeks if the cortisone injections are continued. The present communication shows that cortisone also produces changes in the blood.

Twelve male guinea pigs were given a daily intramuscular injection of 10 mgm. of cortisone acetate (Roussel) for a period of five weeks. Blood was removed by heart puncture on the day prior to the commencement of the cortisone injections and thereafter at the end of each week. The blood films were stained with Giemsa's stain.

Erythrocytes. During the first two weeks of cortisone treatment, the degree of polychromasia and anisocytosis seen in the normal blood picture[2] became increased, and at the end of the second week immature red cells were present in greater numbers. No significant change was noted in the red-cell count; but there was a drop in the hæmoglobin-level from 81 to 70 per cent when tested by the Sahli method.

Leucocytes. The changes in the leucocytes are shown in Table 1.

Table 1. Leucocyte Counts from 12 Guinea Pigs each of which received 10 mgm. of Cortisone Daily for 5 Weeks

No. per cu.mm.	Control	Experimental results No. of weeks of cortisone treatment				
		1	2	3	4	5
Total number of leucocytes	8,700	6,950	4,200	5,100	10,200	9,300
Lymphocytes	5,600	4,800	1,300	1,700	2,700	1,500
Pseudo-eosinophils	2,800	1,900	2,900	3,400	7,200	7,600
Monocytes	300	250	—	—	300	200

The control results in Table 1 show the average number of leucocytes in the twelve animals on the day before the commencement of the cortisone injections; the experimental results give the average number of leucocytes in the animals at the end of each week of cortisone treatment.

It can be seen that the total leucocyte count dropped below normal during the first three weeks of the cortisone injections, then rose above normal during the fourth and fifth weeks of treatment. These changes were accounted for by a sustained fall in the number of lymphocytes and a gradual rise, after the first week, in the number of pseudoeosinophils. Moreover, when the pseudoeosinophil count dropped at the end of the first week, a high proportion of the cells showed multiple nuclear lobes, whereas from the second to the fifth week, as the pseudoeosinophils increased in number, a greater proportion showed a single nuclear lobe indicating increased production of polymorphs.

Yoffey[3] has shown that the administration of compound *E* (cortisone) in doses of 5 mgm. per day for seven days appears to stimulate the formation of red cells in the normal male guinea pig, together with a possible increase in the myeloid cells of the bone marrow. Antopol[4], working on the mouse, reported that a single dose of 2·5 mgm. of cortisone subcutaneously produced depression of the circulating lymphocytes and also an initial granulocytopœnia followed by granulocytosis. He also found that the erythrocyte count showed no significant difference between control and treated animals.

The above results show that the depression of the reticulo-endothelial system which occurs during the early stages of cortisone treatment[1] is accompanied by a fall of the total leucocyte count in the blood. The recovery of the phagocytic activity of the reticulo-endothelial system during the third and fourth weeks of cortisone administration is, however, not associated with a return to normal of the differential leucocyte counts, since the lymphocytes remain reduced in number and the pseudoeosinophils become markedly increased.

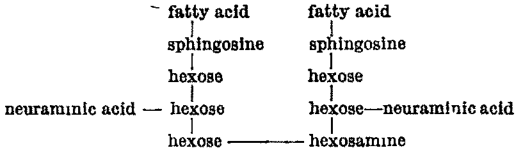
Composition of Gangliosides from Human Brain

Gangliosides are lipids closely allied to the cerebrosides. They were so named because of their occurrence mainly in the ganglion cells of the nervous system, although gangliosides seem to exist in most parenchymatous organs. Klenk *et al.*[1], for example, have isolated gangliosides from brain, spleen and red cells. The composition of ganglioside from brain as given by Klenk had to be modified after the isolation of chondrosamine from brain ganglioside by us[2], and in a recent paper Klenk *et al.* suggested its composition as follows:



In the same paper they also assert the existence of only one type of ganglioside from brain.

The value given for hexosamine by Klenk (7 per cent) is rather low when compared with the value earlier given by Blix[3] and later by Yamakawa and Suzuki[4].

Klenk *et al.* have also investigated the amount of ganglioside in human brain by determining the content of neuraminic acid. On testing the result with another extraction method, I found values 2–3 times higher than those reported by Klenk.

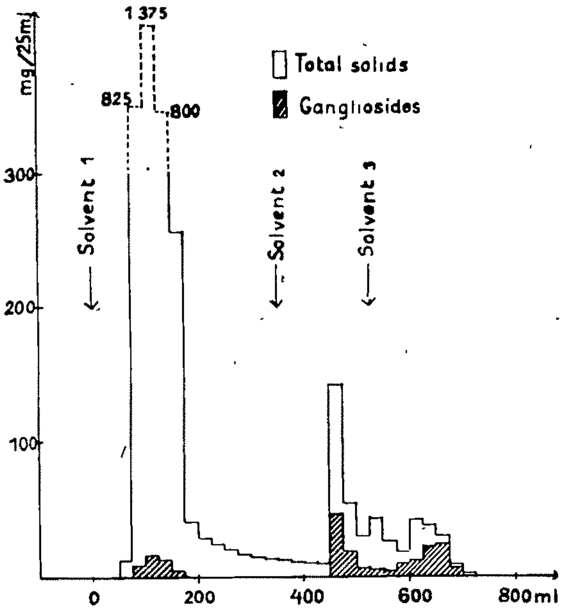


Fig. 1. Chromatogram of 4 gm. of brain lipids on a cellulose column 30 × 400 mm. Solvent 1, chloroform : ethanol : water = 16 : 4 : 1; solvent 2, chloroform : methanol : water = 5 15 : 1; solvent 3, methanol : water = 9 : 1

By the use of an improved method for the separation and the purification[5] of the gangliosides, these discrepancies have been found to be due to the existence of more than one type of ganglioside in human brain.

Grey matter from human brains was homogenized and dried with acetone. The dry substance was extracted with methanol : chloroform (2 : 1 v/v) in a Soxhlet apparatus and the extract evaporated *in vacuo* to dryness. The lipids were dissolved to make a 5 per cent solution in the solvent phase of a mixture of chloroform : ethanol : water (16 : 4 : 1) and placed on the top of a column of cellulose. The column was run with the same solvent until fractions with negligible amounts of solids appeared. The solvent was then changed to chloroform : methanol : water (5 : 15 : 1) and finally to methanol : water (9 : 1). As is seen in Fig. 1, two fractions of gangliosides were separated.

The ratio sialic acid : hexosamine was in the first fraction 3 : 1 and in the second one 12 : 1. (Sialic acid has been isolated from brain gangliosides[6] and is supposed to be the naturally occurring acid in gangliosides.) The gangliosides from the first fraction were contaminated with a large amount of low-molecular substances and formed strands just as the so-called strandin of Folch[7].

The chloroform : methanol eluates from several runs were taken together, dialysed against distilled water at 4° C. and rechromatographed. A main fraction of fairly pure ganglioside was obtained and crystallized from ethanol : water. The crystals, small birefringent rods, were found to be the potassium salt of ganglioside.

Analytical data (calculated on the free ganglioside acid): P, 0 per cent, total-N, 2·97 per cent, hexose (calculated as galactose), 24·6 per cent, chondrosamine (free), 11·6 per cent, sialic acid, 24·1 per cent.

With regard to these data it is likely that the summary formula is as follows:

Fatty acid—sphingosine—hexose—hexose—chondrosamine—sialic acid

I have not yet succeeded in crystallizing the second fraction.

In some pathological conditions, especially in Tay-Sach's disease, the nerve cells are distended by gangliosides. In the brain of an individual suffering from the infantile type of this disease I found mainly gangliosides of the type described above.

A detailed report of this work will be given elsewhere.

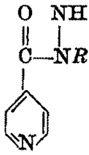
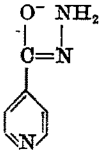
Mode of Action of Isoniazid

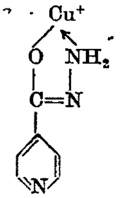
ISONIAZID (*iso*nicotinylhydrazide), which has proved remarkably successful in the treatment of human tuberculosis, has an affinity for the ions of heavy metals. This affinity is only slightly less than those of the common amino-acids[1]. It has been claimed that the action of isoniazid (I, *R*=H) against the tubercule bacillus *in vitro* is increased in the presence of copper[2]. Hence it was suggested that chelation (formation of cyclic metallic complexes) played a part in the therapeutic action of this drug.



(I)



(II)



(III)

In order to form metal complexes, for example, (III), isoniazid must first form the anion (II), which is the chelating species. No anion can be formed by 1-*iso*nicotinyl-1-methylhydrazine (I, *R* = CH_3). This substance has recently been synthesized and found to be virtually inactive[3], thus giving strong support to the hypothesis of chelation.

In the present communication, the determination of the avidity of other hydrazides for heavy metals is recorded. It is seen from Table 1 that of the two isomers of isoniazid, nicotinic hydrazide (which is biologically inert) has approximately the same affinity for metals as isoniazid, whereas picolinic hydrazide, which is about eight times less effective biologically, has 10^3–10^5 times the affinity for metals. Table 1 also includes an aromatic, and an aliphatic, hydrazide which have much the same avidity for metals as isoniazid but have far less biological activity. Thus, although the ability to form chelate compounds seems to be essential for the functioning of isoniazid, it now becomes clear that some other factor is of over-

riding importance. The incorporation, by the living cell, of isoniazid into diphosphopyridine nucleotide[4] (in the place of nicotinamide) does not explain its antitubercular action, because cyanacetic hydrazide is not a structural analogue of nicotinamide. Yet cyanacetic hydrazide, although weak, has been used successfully in human tuberculosis[5], and is apparently acting in the same way as isoniazid, because organisms resistant to one are resistant to the other[6].

The specificity of these hydrazides for *M. tuberculosis* has yet to be explained: none of the substances in Table 1 was bacteriostatic to *Staph. aureus* or *Strept. haemolyticus* in broth at pH 7·3 (37° for 24 hr.) even at 10^{-2} *M*, whereas 8-hydroxyquinoline (control) inhibited both organisms at 10^{-5} *M* (Marshall, J. H., unpublished work).

The ionization constants were determined by potentiometric titration at 20°, the two basic functions being separated by the method of Noyes[7]. The stability constants (K' for the 1 : 1 complex, for example, III, K'' for the complex formed by adding one more ion of ligand, and K_s, which is the product of K' and K'') were obtained by potentiometric titration in the presence of one equivalent of the metal ion[8].

Prof. R. Knox and Dr. J. H. Marshall are thanked for permission to quote from their unpublished biological results; and Mr. E. P. Serjeant for skilled technical assistance; also Mr. D. E. Seymour, of Herts Pharmaceuticals, Ltd., for gifts of nicotinic and picolinic hydrazides, and Dr. Maxwell Savage, of S. Maw, Son and Sons, Ltd., for the cyanacetic hydrazide.

Formation of Iron-binding Compounds by Micro-organisms

THE metabolic activity of certain micro-organisms is well known to be dependent on the iron concentration of the culture medium. For example, where cultured at controlled levels of iron, *Corynebacterium diphtheriae*[1] and *Aspergillus niger*[2] produce large amounts of toxin and citric acid respectively. Recently we have reported[3] the production of ferrichrome A by *Ustilago sphaerogena* when this fungus is grown under conditions of controlled iron supply.

In the present investigation a study has been made of the tendency of various microbial species to form iron-binding compounds under conditions similar to those used[3] for the production of ferrichrome A. The results demonstrate that at least three species (*Bacillus subtilis, Aspergillus niger* and *Bacillus megaterium*) can be induced to form such compounds. Several strains of *Bacillus subtilis* and *Bacillus megaterium* were examined and found to give essentially similar results.

The analytical measure employed to follow the formation of the iron-binding substances consisted in the addition to 4 ml. of the cell-free medium of 1 ml. of a solution containing 1 mgm. per ml. of ferric ion or, alternatively, ferrous ion followed by aeration. The optical density of such solutions was then measured at the wave-length of maximum absorption of the principal coloured iron complex present. These wave-lengths, as established on the extracted and purified substances, were 510, 440 and 440 mµ for the *Bacillus subtilis, Aspergillus niger* and *Bacillus megaterium* cultures, respectively.

In a series of experiments designed to show that only intermediate levels of iron are effective, the basal medium[3] was treated with 8-hydroxyquinoline and extracted with chloroform prior to sterilization and inoculation. The formation of the ferric-ion binding agent by *Bacillus subtilis* as a function of time and initial iron concentration is shown in Fig. 1. The product of this fermentation, the ferric derivative of which exhibits a deep purple colour at neutral pH, has been purified by solvent-extraction procedures and appears to have the general properties of a polyhydric phenol. The chemical nature of the compounds formed by *Aspergillus niger* and *Bacillus megaterium* (Table 1) is unknown, although judging from their spectra they may be more closely related

Table 1. FORMATION OF FERRIC ION-BINDING COMPOUNDS BY *Aspergillus niger* AND *Bacillus megaterium*

22	0·14	0·12	0·15	0·20	0·34	0·13
32·5	0·09	0·07	0·09	0·42	0·62	0·24
46	0·20	0·34	0·08	0·41	1·20	0·29
57	0·52	0·56	0·27	0·27	0·90	0·21
79·5	1·50	0·95	0·39	0·17	0·60	0·14

* No detectable iron-binding compounds were observed with initial iron concentration of 500 μgm./l. or greater.

to ferrichrome[4] or ferrichrome A [3]. The ferric chelate of citric acid, although yellow in colour, does not have an absorption maximum in the higher wavelength region employed in the present work.

Escherichia coli and a *Pseudomonas* species, when grown in the unpurified medium, gave no visual evidence of the formation of iron-binding agents. It is, of course, conceivable that some of these compounds might provide colourless derivatives with ferric ion; in that event they would be more difficult to detect. Our success in finding the substances with the three species described above may be connected with the more vigorous growth and higher iron requirement of the bacilli and fungi.

From our results (Fig. 1 and Table 1) it is clear that the extracellular appearance of the iron-binding substances is strongly dependent on the initial iron-level of the medium. This suggests that these compounds are involved in an iron sequestering and transferring system, the latter either initiated or magnified by the organism during iron deficiency. The substances mentioned here form very stable ferric derivatives, probably chelate compounds, since the bound iron cannot be precipitated even at pH values of 10–11. We have repeatedly observed that, when the test organisms are grown in stainless steel fermentation equipment, no trace of iron-binding substances can be found.

An alternative explanation for the mode of action of the new compounds would be that they act as a by-pass around the normal terminal electron transport chain. It is of interest that all of these ferric chelates can be reduced with hydrosulphite and are very rapidly autoxidizable.

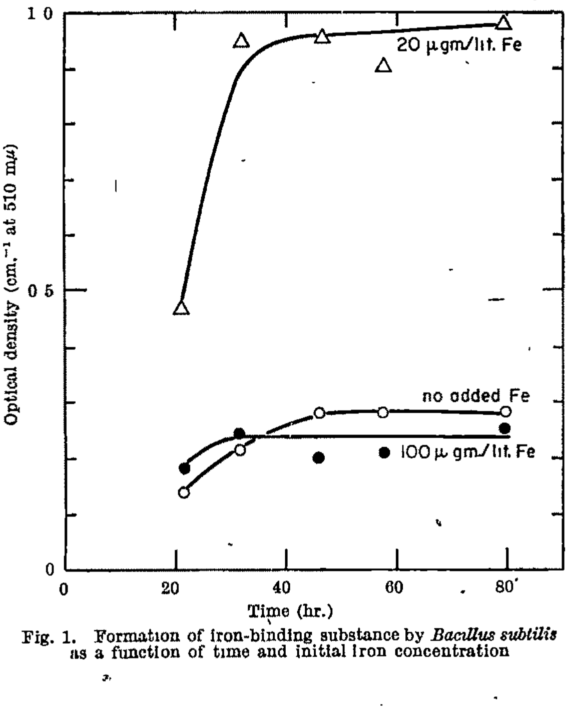

Fig. 1. Formation of iron-binding substance by *Bacillus subtilis* as a function of time and initial iron concentration

Bacillus subtilis, but not *Bacillus megaterium* or *Aspergillus niger*, excretes large amounts of porphyrin in addition to the ferric ion-binding agent described above. This porphyrin has been shown by P. M. Townsley in this laboratory to be mainly coproporphyrin III.

Further experiments are in progress with the iron-binding substances produced by micro-organisms. Of particular interest is the study of their structure, specificity for metal ion (stability) and biological activity.

This work was supported in part by a grant from the Eli Lilly Company.

Amino-Acid Secuence in a Hypertensin

THE isolation and purification of a hypertensin peptide, resulting from the action of rabbit renin on ox serum, have been described recently by one of us. Its amino-acid composition was consistent with a decapeptide structure containing the following eight amino-acids: leucine (1), phenylalanine (1), tyrosine (1), proline (1), aspartic acid (1), arginine (1), valine (2) and histidine (2). Application of the fluorodinitrobenzene technique of Sanger showed that the N-terminal residue was aspartic acid[1]. The amino-acid sequence in this peptide has been determined by the following methods:

(1) Treatment with carboxypeptidase in the presence of di*iso*propyl phosphorofluoridate revealed leucine as the C-terminal amino-acid. The two adjacent amino-acids were shown to be phenylalanine and histidine; but their sequence could not be determined by the technique used.

(2) Partial acid hydrolysis with concentrated hydrochloric acid (36 per cent w/w) at 37° for three days, followed by paper chromatography to separate the products, yielded histidyl leucine. The remaining peptides could not be purified. It follows that the C-terminal sequence is · · · ·Phe·His·Leu.

(3) Stepwise degradation by the Edman method[2] indicated the N-terminal sequence Asp·Arg·Val·Tyr· · · ·.

(4) Trypsin digestion split off the peptide Asp·Arg which was isolated by paper chromatography. Application of the fluorodinitrobenzene technique to the whole digest showed that valine was the N-terminal residue of the other peptide. This confirmed the N-terminal sequence Asp·Arg·Val · · · · in hypertensin.

(5) Chymotrypsin digestion gave three products which were separated by paper electrophoresis; two tetrapeptides, (*a*) and (*b*), containing Asp, Arg, Val, Tyr, and His, Pro, Val, Phe, respectively, and the dipeptide His·Leu. Treatment of the digest with fluorodinitrobenzene revealed Asp, Val and His as the N-terminal residues of these peptides. Valine was therefore the N-terminal residue of peptide (*b*).

The C-terminal sequence · · · ·Val·Tyr was confirmed in peptide (*a*) by means of carboxypeptidase. Peptide (*b*) gave only phenylalanine even after digestion for 18 hr. at 37° with the enzyme at an enzyme : substrate molar ratio of approximately 1 : 40. This indicated the sequence · · · ·Pro·Phe, and this was supported by the results of the Edman degradation on peptide (*b*), which showed that the sequence of the first three residues was Val·His·Pro· · · ·.

(6) The action of aminopeptidase[3]: although not useful in our hands for elucidation of the sequence in hypertensin on account of the very rapid liberation of all the amino-acids present, aminopeptidase liberated free aspartic acid and not asparagine. In view of the optical specificity of this enzyme, the amino-acids in hypertensin must have the L-configuration.

The sequence of residues in this hypertensin is therefore Asp·Arg·Val·Tyr·Val·His·Pro·Phe·His·Leu. Confirmation of this structure is being attempted by synthesis.

The Pigment, Trichosiderin, from Human Red Hair

Sorby[1] first described the pink pigment extractable from human red hair by hot acids, and its properties were further investigated by Flesch and Rothman[2]. In strongly acid solutions, the absorption curve shows a hump above 475 mμ with a maximum at 535 mμ (Fig. 1, curve 4), but this disappears at alkaline *p*H. Complete extraction of trichosiderin does not appreciably change the hair colour, and the contribution of this substance to the total pigmentation is uncertain.

In the present work bright red hair from a single subject, chosen because of its very high yield of trichosiderin, was studied. The washed hair was suspended in *N*/10 sodium hydroxide (100 mgm./10 ml.) at room temperature for 12 hr.; the hair swelled but did not disintegrate. The resulting orange-yellow extract (curve 1) was carefully neutralized and a further amount of concentrated hydrochloric acid (specific gravity, 1·18) was added to give a final concentration of 6 per cent. A white precipitate was centrifuged off, leaving a pale yellow supernatant (curve 2). Since the *p*H of the acidified extracts was in the region of 0·2, it is clear from the absorption curve that trichosiderin could not have been present. On heating the extract in a water-bath at 100° C., however, a pink colour developed within five minutes, and the solution also showed a reversible change to yellow at alkaline *p*H and pink pigment could be precipitated out at *p*H 7·0 as described by Flesch and Rothman[2]. It seems, therefore, that weak alkali extracts a precursor whi is readily converted to trichosiderin on heating acid. Approximately the same amount of trich siderin is obtained either by direct acid extracti or by alkali extraction followed by acidification a heating (curves 3 and 4).

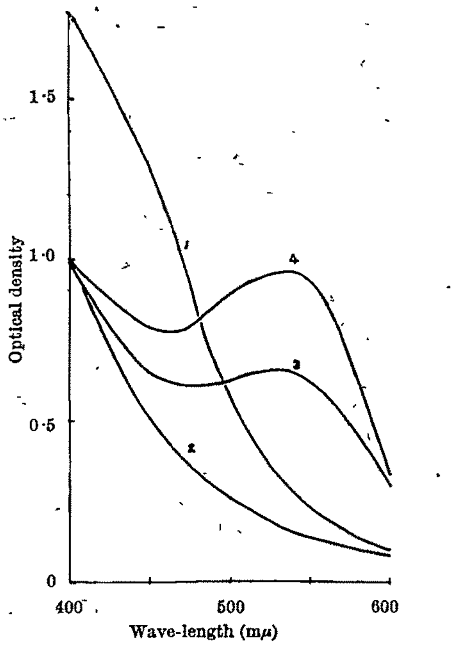

Fig 1. Absorption curves of hair pigment extracts from strong red hair of a single subject. Cell length, 1·0 cm.; 100 mgm. hair/ 5·0 ml. solvent. (1) Extract in N/10 sodium hydroxide for 12 hr. at room temperature. (2) Curve 1 acidified to 6 per cent with conc. hydrochloric acid. (3) Curve 2, after holding at 100° C for 30 min. (4) Direct acid extract with 6 per cent hydrochlori acid for 2 hr. in a sealed tube

The use of *N*/1 sodium hydroxide results in parti destruction of the trichosiderin precursor and al extracts other red pigments which are insoluble acid and may be the main pigmentary component

If acidified but unheated alkali extracts (*N*/ sodium hydroxide) are chromatographed on a tal 'Celite' column[3], the orange-yellow pigment remai at the top and the colourless eluate yields no tra of trichosiderin on acidification and heating. If t pigment is then run off the column by addition dilute ammonia, the yield of trichosiderin from t fractions is clearly related to the intensity of the initial yellow colour. The pigment from alk extracts can also be adsorbed at the top of a ma nesium carbonate column[4], forming a strongly re brown layer which is not shifted by a variety of s vents, including aqueous solutions of ethylene chlo hydrin or of urea. If the pigment is removed l extrusion, a strong pink colour develops on heati it in acid solution. It is likely, therefore, that t trichosiderin precursor is an acid-soluble yellow orange pigment.

Some twenty specimens covering a wide range non-red hair colours and including albino hair yield pale yellow alkali extracts which became paler acidification but did not yield trichosiderin wh heated. The absorption curves of these yellow alk extracts have a simple concave form, whereas t alkali extract of strongly red hair (curve 1) distinctly sigmoid.

I wish to thank Dr. S. P. Datta for making *p* measurements with the glass-electrode, and t

Determination of Arginine

The orange-red colour produced by arginine and other mono-alkyl guanidines in the presence of α-naphthol and hypochlorites or hypobromites[1] would probably be more widely used in analysis, were existng methods capable of a stable calibration or more reproducible.

In 1948, Sakaguchi[2] introduced oxine in place of α-naphthol with some improvement; but his adaptation used the rather inferior analytical procedure of Weber[3]. The substitution of oxine for α-naphthol in Macpherson's method[4] brings about a most striking all-round improvement. Sensitivity is increased, the blank colour in the absence of arginine is reduced, a inear and stable calibration can be obtained and the tandard error of a single measurement is reduced o rather less than 1 per cent compared with 4 per ent for the original Macpherson procedure. The ntensity of colour varies with temperature; thereore, the reagents prior to mixing, and the solution up to the time of measurement, should be kept in a hermostat. The calibration of a Spekker absorptiometer (using Kodak Non-Photographic Filter No. 549) has not varied over two years.

7-Chloro-oxine gives yet higher sensitivity and ower blanks than oxine. The concentration of the ypobromite solution should, however, be only 60 per ent of that used for oxine and α-naphthol. When rginine is determined in whole protein hydrolysates, ome density is always contributed by other aminocids[5]. The absorption spectrum due to the other mino-acids differs from that of the Sakaguchi olour, but overlaps it and cannot be eliminated by hoice of filter. The density due to other amino-acids produced with 7-chloro-oxine amounts to only about alf that obtained with oxine or α-naphthol. 5 : 7-Dihloro- and 5 : 7-dibromo-oxine show still lower blank ensities; but the lower solubility of these two compounds makes it difficult to employ a sufficient oncentration to get the highest sensitivity. They eplace oxine with advantage in the detection of lkyl-guanidines on paper chromatograms by methods nalogous to that of Jepson and Smith[6].

A number of other derivatives of oxine α-naphthol nd related compounds are being examined.

Electrical Activity in the Cockroach Cerebrum

Information concerning electrical activity within the central nervous system of the higher invertebrate phyla is unusually meagre. This has been partially due to the inadequacy of recording techniques. It has proved possible, however, using capillary microelectrodes of less than 0·5μ tip diameter, to make recordings from the cockroach (*Periplaneta americana*) proto- and deutero-cerebrum, and to correlate particular types of activity with specific structures within the brain. In the central nervous system of insects, as in most other invertebrates but unlike the vertebrates, the neuron somata are separated from the synaptic (neuropile) regions.

The cockroach was fixed with pins and 'Plasticene' so that the thoracic and abdominal spiracles remained open for respiration while the head was bathed with a perfusion fluid[1] made isotonic with 0·1 *M* sucrose. The brain was exposed by removing the ocelli and frontal surface of the head capsule. After desheathing the protocerebrum and antennal lobes, microelectrodes filled with 3 *M* potassium chloride could be inserted at will. Electrode positions were roughly determined by measurement from the surface contours and later verified in the fixed and sectioned brain. Electrical stimulation was applied to the antennal nerve 1–2 cm. from the head.

Characteristic responses to stimulation were found in the antennal glomeruli, where sensory fibres join up with association neurons, and in most structures of the homolateral protocerebrum. The most prominent response, however, came from the homolateral corpora pedunculata. This was a large, extracellularly recorded, negative spike (often more than 30 mV. in the calices and peduncle) which apparently resulted from synchronized activity in the processes of the globular cells of the corpora pedunculata. It rapidly became fatigued at stimulation frequencies of more than 1 per sec., and had a rather variable latency (40–70 m.sec.). Occasionally the spike was repeated once or twice at approximately 10-m.sec. intervals; but in most preparations it was single. The form of the spike in the different regions of the corpora pedunculata suggests that it originated in the calices and passed down the peduncle to the α- and β-lobes, where it terminated (Fig. 1). This was substantiated by latency differences between the calyx and the α- and β-lobes. Pre-spike activity was most prominent in the calices, and was presumed to result from activity in association fibres coming from the antennal glomeruli. In addition to the large synchronized spike, repetitive discharges in single units and slow potential changes were recorded from various regions of the corpora pedunculata. In some of the cases, slow potentials seemed to be associated with an inhibition of small amplitude, spontaneous activity.

Cockroaches usually jump suddenly when an antenna is pinched or otherwise strongly stimulated. It was first thought that the large corpora pedunculata spike described above might be associated with this generalized response. Recordings from the thoracic nerve cord eliminated such a possibility, however, for the latency of the giant fibre responses in the thorax which mediated the jump response was less than 10 m.sec. These thoracic responses also remained when the major portion of the homolateral corpora pedunculata was removed, indicating a direct connexion between the antennal nerve and giant fibres

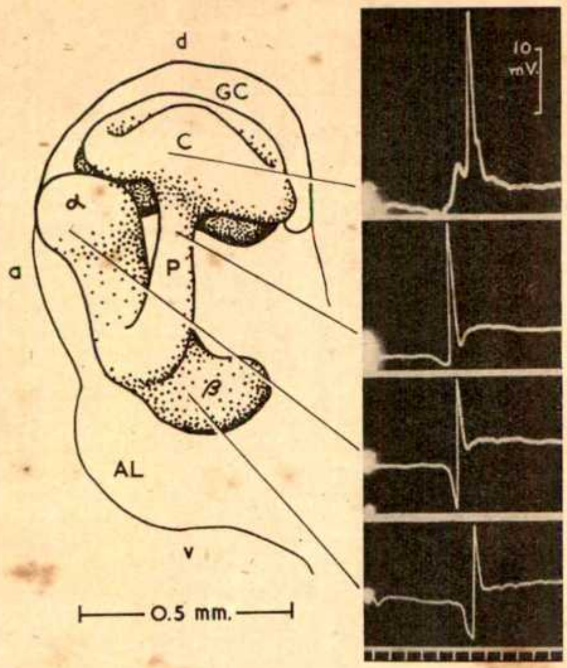

Fig. 1. Diagram of cockroach brain (lateral view) showing responses to antennal stimulation obtained in varying portions of corpora pedunculata; *C*, calyx; *P*, peduncle; *α*, *α*-lobe; *β*, *β*-lobe; *GC* globular cell bodies the processes of which form most of the corpora pedunculata; *AL*, antennal lobe; *d*, dorsal; *a*, anterior; *v*, ventral. Upwards on records is negative; 10-m.sec. time marker; stimulus artefact triggered sweep

leaving the lower portion of the deutero-cerebrum. Although further ablation studies suggested that the corpora pedunculata are important in antennal function and locomotion, the role of the large spike remains unknown. If tracts connect the α-lobe of the corpora pedunculata with the antennal lobe, as recently described in the Hymenoptera[2], the large spike could be a link in a circular pathway: antennal glomeruli – corpora pedunculata (calyx to α-lobe) – antennal lobe.

More complete analyses of the corpora pedunculata responses and other activity in the cockroach brain are in progress and will be reported elsewhere.

A New Quantitative Method for Antigen–Antibody Titrations in Gels

VARIOUS methods have been devised for the quantitative analysis of precipitating antigen–antibody systems in gels[1-4]. Because they each involve intricate and time-consuming measurements there still exists the need for a simple assay technique in which conditions are readily stabilized and duplicated, and in which the end-point does not depend on the precise measurement of precipitation band distances. Such a method is now reported.

It is a modification of the Ouchterlony[5] punch-plate double diffusion technique. A stainless steel punch was designed to cut simultaneously a large central well and six smaller equidistant peripheral wells in poured agar plates. The body of the punch and central cutter were machined from a solid billet of stainless steel, the cutter being bored to $\frac{15}{32}$ in. inner diameter and turned to $\frac{1}{2}$ in. outer diameter. The peripheral cutters were made from $\frac{1}{8}$ in. bore stainless steel hypodermic tubing and set into holes drilled in the punch body. All cutters were chamfered on the inside to provide a razor-fine cutting edge. Distances between opposing edges of central and peripheral cutters, as measured with a travelling microscope, are 5·78 ± 0·06 mm., an accuracy of ± 1 per cent.

In practice, 1 per cent clarified New Zealand agar in saline, with 1 per cent sodium azide as preservative, is poured into 2½ in. Petri dishes, 8 ml. per dish. After the gel has set in the refrigerator, the punch is placed centrally on the gel and pressed down with a firm, quick thrust. A capillary tube attached to a water vacuum pump is inserted down the shaft of each cutter in turn and the agar plug removed by suction. On withdrawal of the punch a pattern of clean-walled, uniformly placed wells is left in the agar. Dozens of identical plates can be prepared quickly in this way.

Into the large centre well 3–4 drops of antiserum are deposited and a glass or aluminium plug, about three-fourths the diameter of the well, placed centrally. The latter serves merely as a space-filler to spare antiserum. The Petri dish is closed and stored at 37° C. over saline in a canister, to prevent drying. 48–72 hr. later, depending on predetermined conditions for each antigen–antibody system, accumulated saline is removed from the peripheral wells and suitable dilutions of antigen added in clockwise direction, the starting well being noted by a pencil mark on the Petri dish. Each well is filled flush with its rim. After further incubation for 24 hr. the precipitation lines have formed and remain constant indefinitely thereafter.

At those wells where antigen concentration is relatively high the precipitation bands develop as an arc or parabola. Around wells of lower antigen concentrations a circle of precipitate is formed, completely surrounding the well. The first well which is completely encircled is taken as the end-point.

This end-point is objective and unequivocal. It seems capable of distinguishing between differences in concentration of the order of 10 per cent. Plates set up in duplicate and triplicate have uniformly given identical end-points. Though the end-point seems constant from one time to another if conditions are carefully controlled, for routine assays it is probably preferable to include a reference antigen as a standard.

So far this study has been based mostly on a system of anti-golden rod pollen rabbit serum versus a commercial golden rod pollen extract. As the extract came as a 50 per cent glycerine–saline solution, 50 per cent glycerine–saline was used as the diluent. Dilutions used began at 1 : 10 and rose by steps of 2 through the next five wells to 1 : 20.

Other systems have also been briefly examined and the technique described seems to be generally applicable. It has been noted that where two major antigens are present in a system it is possible to titrate for each independently, each antigen presenting a well-circling precipitation band at its own distinctive dilution. When conditions are suitably chosen the two end-points may appear on a single plate.

I am indebted to Mr. C. G. Green and Mr. R. D. Peters of the Instrument Section for construction of the punch.

Irradiation of Thiourea: Effect of Dose-rate upon the Chain Reaction

THIOUREA in aqueous solution is known to exert a highly protective power in radiation experiments[1]. When thiourea is irradiated with X-rays, gamma-rays or electrons, free sulphur is liberated[2].

A quantitative investigation of this reaction reveals interesting and unusual features. Apart from dependence upon *p*H and concentration and certain shifts of the *p*H in unbuffered solutions, oxygen has a greater effect than in other oxygen-dependent reactions. The yields, which are very low in absence of oxygen, are increased about four times in air-saturated solution and increase further to twelve times for oxygen saturation at dose-rates between 400 and 1,000 r./min. The most important characteristic, however, is that this reaction is a chain reaction with a very marked dependence upon dose-rate.

When the logarithm of G_s (number of sulphur atoms per 100 eV. of energy absorbed) for various dose-rates is plotted against the radiation dose, a family of curves results which have the following characteristics: there is an induction period during which the G_s values increase to a maximum and then remain constant when the radiation dose is further increased. Each dose-rate has its own maximum G_s value, which is the greater the slower the dose-rate (for example, 17,000 for 0·71 r./min.). The attainment of the maxima is shifted towards bigger doses with decreasing dose-rates. It is in practice scarcely possible to reach the maximum experimentally at very low dose-rates, because the radiation times required would be inconveniently long. The value of the maxima can, however, be satisfactorily extrapolated since the results for medium and higher dose-rates establish that G_s is nearly inversely proportional to the dose-rate (see Fig. 1).

The presence of oxygen is necessary for the chain reaction to occur. Lowering the oxygen tension from 100 per cent oxygen in the gaseous phase to 20 per cent causes a decrease of the G_s values but does not abolish the dose-rate effect. No after-effect of the irradiation has been observed.

The importance of this reaction, if other similar examples can be found, would appear to lie in the fact that the efficiency of ionizing radiations at very low dose-rates, as may occur with radioactive fall-outs, may be much greater than they are thought to be at present. A short summary of part of the results of this investigation is in the course of publication in the proceedings of the International Conference on Radiobiology held in Cambridge (August 14–17, 1955), and a full account with experimental details will be published elsewhere.

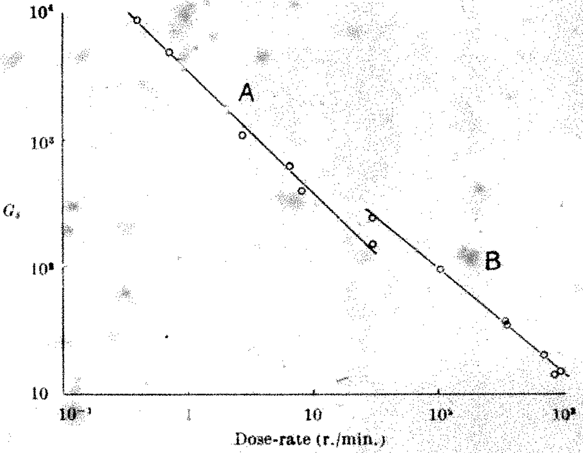

Fig. 1. Curves plotted for: (*A*) Total dose 10^4 r. before maximum G_s; (*B*) total dose 3×10^5 r. at maximum G_s

Rhythmic Biting Activity of Certain East African Mosquitoes

IN a recent communication in *Nature*, Corbet and Tjønneland[1] have described bimodal flight activity in East African Trichoptera, with peaks of activity just after sunset and before sunrise. A similar pattern is apparent in the biting cycle of various forest mosquitoes, and some years ago I introduced the term 'eo-crepuscular' to describe this type of activity[2].

In most of the more specialized mosquitoes the pattern of biting activity is repetitive from day to day and in addition many show a marked preference for a particular level, such as the forest canopy[3]. Though the biting cycles of most common species have now been studied in some detail, the reasons for these activity patterns are still, in many cases, not fully explained. It is therefore a matter of considerable interest to find a close correspondence between the biting cycle of a common mosquito, *Taeniorhynchus* (*Coquillettidia*) *fuscopennatus* Theo., and the flight rhythm of *Cheumatopsyche* sp. nov. as shown by Corbet, more particularly as the methods of capture were entirely different and as the cycle shown by the mosquito is related to biting activity, whereas the caddis fly probably feeds little if at all in adult life.

The results shown here for *T. fuscopennatus* (Fig. 1) are taken from a long series of 24-hr. catches now in progress in a patch of forest near Entebbe, Uganda, about sixty-five miles south-west of Corbet's catching station at Jinja. These catches of biting females are being carried out 65 ft. above ground, in the forest

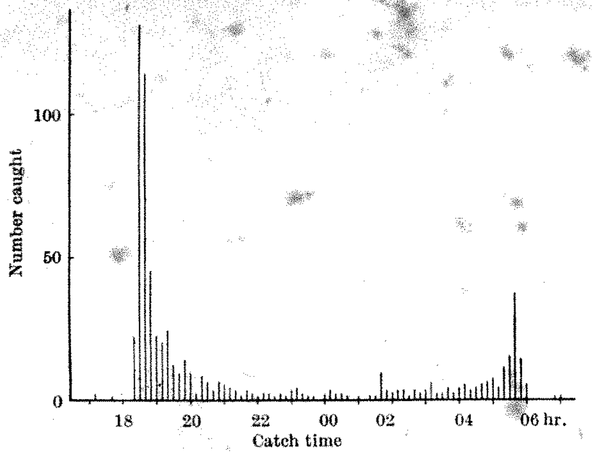

Fig. 1. Sunset at 18.00 hr.

canopy, with human bait, by methods described elsewhere[4]. The time of capture of each specimen is recorded to the nearest minute but, to permit comparison with Corbet's results, the figures have here been grouped by 10-min. periods. The sample under discussion was obtained in the twenty-five catches so far carried out, the number of *T. fuscopennatus* being 668. As the sunset period is most important in mosquito work and as the annual variation in sunset time is more than half an hour at Entebbe, Local Mean Time and East African Standard Time are not adequate for the work in hand. Instead, a special 'Catch Time' is used, this being accurately adjusted to the time of sunset, which is always recorded as 18.00 hr.[5]. In Corbet's communication East African Standard Time is given. It is found that on the evening of the catch he discusses (January 5, 1955) sunset occurred at Jinja at 18.56 ± 2, E.A.S.T. It is now seen that the first wave of activity in *T. fuscopennatus* reaches its peak in the third 10-min. period after sunset and in *Cheumatopsyche* in the fourth period. The sunrise peaks are similarly related to the period before sunrise. In both cases there is only ten minutes difference between the maximum for the mosquito and that for the caddis.

Corbet mentions that his study was concerned with the cyclical emergence of insects from Lake Victoria. It is not felt, however, that emergence cycles can have much effect on the biting-cycles of mosquitoes, as the females do not bite on the day of emergence, and many of them not until the third day of adult life. He also mentions that more intense reproductive activity at sunset may be the reason why the sunset peak is much larger than that at dawn. Elsewhere, Lumsden[5] has advanced the view that in mosquitoes with a double activity peak different age-grades may fly at different times, while Harker[6] has shown that, in the cockroach, activity rhythms may have a neurosecretory basis. I believe that in insects showing abrupt eo-crepuscular activity the control of this activity is mainly microclimatic.

The sudden nature of such activity peaks is well shown by the figures for *T. fuscopennatus*, where 37 per cent of the entire night catch was taken in the 20-min. period during 18.21–18.40 hr. The abruptness and short duration of the wave of activity suggest that a particular level of low light intensity may be important—it will be remembered that near the equator, as at Entebbe and Jinja, light intensity changes very rapidly indeed at dawn and sunset. Such an explanation is supported by current work on another mosquito, *Aedes* (*Finlaya*) *ingrami* Edw. This species reaches its peak of biting activity before sunset, and in this case the small peak at dawn occurs after, not before, sunrise. Under forest conditions in East Africa, the main climatic difference between dawn and sunset is in temperature. In both periods low light intensities prevail and in both saturation-deficiency is very low. While, however, sunset is a relatively warm period, dawn is the coldest period of the twenty-four hours[2,3]. This may be the main reason for the difference between the numbers taken biting at these times, as it is well known that in many species biting activity is reduced by low temperatures.

The complexity of mosquito biting cycles is not, however, fully indicated by catches confined to one level. Where catching goes on simultaneously at various levels, marked qualitative differences in the respective cycles may be found, as has been shown in *Anopheles* (*Myzomyia*) *gambiae* Giles[4]. Current work reveals a similar state of affairs in *T. fuscopennatus*. Broadly speaking, peaks of activity are shorter but more intense in the canopy than in the under-story, and in the under-story than at ground-level.

As Corbet was dealing with a very wide range of numbers, the scale of his histogram is of necessity logarithmic. Convenient though this scale may be, it does not bring out clearly the very abrupt nature of the peaks—nor the enormous quantitative difference between them. Deducing the arithmetical totals from his figure, it is found that the highest 10-min. period after sunset yielded more than twenty times as many insects as the highest dawn period. For this reason an arithmetical scale has been used in the present communication.

Insecticide Resistance in *Anopheles gambiae* Giles

Although authenticated cases of physiological resistance to insecticides on the part of anopheline mosquitoes have been reported from Europe[1], North America[2] and the Far East[3], no such occurrence has so far been reported from Africa. The following preliminary observations appear to constitute a *prima facie* case of such resistance and it has therefore been considered desirable to place them on record.

In connexion with the Western Sokoto (Northern Nigeria) Malaria Control Pilot Project, an area of about 300 square miles has been set aside for treatment with dieldrin. In this zone are two large communities in which all houses have been treated as follows: Birnin Kebbi—two sprayings with dieldrin 50 per cent wettable powder at 25 mgm. dieldrin per sq. ft. followed by one at 50 mgm. per sq. ft.; Gwandu—three sprayings with the same insecticide at 25 mgm. per sq. ft.; all sprayings were at intervals of six months, commencing in June 1954.

Table 1

Place	Mosquito material	Toxicant	Concentration per cent	No. of mosquitoes exposed	Per cent mortality
Birnin Kebbi (dieldrin zone)	Bred from wild larvæ	Dieldrin	4·0 2·0 1·0 0·5	64 62 70 61	83 45 16 5
Gwandu (dieldrin zone)	Wild-caught	Dieldrin	4·0 2·0 1·0 0·5	15 15 15 15	93 60 33 20
Birnin Kebbi (dieldrin zone)	Bred from wild larvæ	DDT	4·0 2·0 1·6 1·3 1·0 0·5	15 25 16 16 20 11	100 92 31 6 5 0
Argungu (unsprayed zone)	Wild-caught	Dieldrin	4·0 2·0 1·0 0·5	35 35 36 14	100* 100* 100* 100†

* 100 per cent knocked down during 1 hr. exposure period.
† 57 per cent knocked down during 1 hr. exposure period.

The test for susceptibility to insecticides devised by Busvine and Nash[4] was applied to *A. gambiae* from these two towns in the dieldrin zone and from an unsprayed town about fifteen miles outside the sprayed area. These tests consisted of exposing fed *A. gambiae* females (eight wild-caught or bred from wild-caught larvæ) for 1 hr. to filter papers impregnated with a mixture of one part of toxicant solution in Risella oil and two parts of trichlorethylene, followed by a recovery period of 24 hr. Controls were run using Risella oil diluted as before but without dissolved toxicant, control mortalities being low. Results are given in Table 1.

The median lethal concentrations, estimated graphically, for the Birnin Kebbi material were: dieldrin, 2·0 per cent; DDT, 1·6 per cent. Comparable figures for the mosquitoes from the unsprayed Argungu area cannot be given, because all were killed by the lowest concentration used (0·5 per cent). However, in the following communication, Busvine gives median lethal concentrations for susceptible colonies of *A. gambiae*, as follows: dieldrin, 0·25 per cent; DDT, 0·95 per cent.

The difference in DDT-tolerance indicated by the figures 1·6 per cent and 0·95 per cent may not be significant, but the eight-fold difference in tolerance of dieldrin, while by no means as striking as some reported cases of insecticide resistance, is probably sufficient to enable the species to survive the control measures at present in force. It may be mentioned that houseflies from the same two towns, which returned to normal numbers in the sprayed zone after the first year of treatment, have shown a seven-fold increase in their tolerance of dieldrin.

Normal Resistance-levels of *Anopheles gambiae* to Various Insecticides

In several areas where large-scale residual spraying programmes have been undertaken against mosquitoes, some increase in their resistance to insecticides has been suspected after a year or two. Unless the increase is very great, it is not easy to establish from field-observations, which may be influenced by seasonal variations and, possibly, the inefficiency of operators. Laboratory comparisons of specimens from sprayed and unsprayed areas are desirable; but very little is known of natural variations in resistance of any species in different localities. There is much to be said, therefore, for preliminary determination of resistance-levels before undertaking large spraying campaigns.

This communication records some preliminary results on the normal resistance of the African mosquito *Anopheles gambiae*. The method of measurement was introduced by Busvine and Nash[1], but is more fully described in an annex to the Fifth Report of the World Health Organization Expert Committee on Malaria[2]. Two strains of *A. gambiae* were used, both of which had been reared for a number of generations in the laboratories of the Ross Institute in London, as mentioned by Wall[3]. One was a West African colony from Lagos, Nigeria, which had been reared for about twenty generations in captivity. The other had been obtained from Tengeni, Tanganyika, and reared in London for about five generations. The mosquitoes were reared at 27° C. and tested at the same temperature, a few hours after a blood meal.

Tests were carried out with each insecticide on four different days, over a period covering about three generations of the mosquitoes. On each occasion, about three replicates of five mosquitoes were exposed at each concentration tested. When the results were carefully examined, it was evident that there was no appreciable difference between the two strains in resistance to DDT or gamma BHC, so the results were combined. Only the West African strain was used in the tests with dieldrin. The results, corrected for the overall control mortality (8 per cent), were as follow:

Per cent DDT	2	1	0·75	0·5
Per cent kill	91	53	34	13
Per cent gamma BHC	0·06	0·03	0·02	0·01
Per cent kill	100	96	74	24
Per cent dieldrin	0·45	0·40	0·30	0·20
Per cent kill	100	95	59	29

Logarithms of concentration/probit mortality regression lines were drawn to these results, and the following median lethal concentrations were estimated visually: DDT, 0·95 per cent; gamma BHC, 0·015 per cent; dieldrin, 0·25 per cent.

Mr. J. G. Halcrow kindly allows me to quote some comparable results which he obtained in unsprayed areas of Mauritius in 1954, using the same method, with adults which emerged from larvæ collected in the field:

Per cent DDT	2	1	0·5
Per cent kill	100	75	41
Per cent dieldrin	0·5	0·3	0·2
Per cent kill	100	64	28

These figures indicate a slightly greater susceptibility to DDT (median lethal concentration, 0·7 per cent), but the resistance to dieldrin was identical with that of the laboratory colonies in London.

So-called 'Glacier-Worms' in New Zealand

Some years ago, during an expedition to the St. Elias Mountains on the Alaska–Yukon boundary, I found some oligochaetous annelids, which are known to occur throughout the western coastal ranges of North America, and are usually referred to as 'glacier-worms' or 'ice-worms'[1]. In my report of this find I asked for any information that might be available upon the occurrence and distribution in general of species of the particular genus, *Mesenchytraeus*, to which these worms belong. However, not a single reply has since been received in answer to that inquiry.

Soon after coming to New Zealand in 1950, I heard that on the Franz Josef Glacier, Westland, small insects, which simulated worms, had been seen in the ice. Indeed, these creatures, and also spiders, had been reported by the pioneer surveyors, C. Douglas and A. P. Harper, in the early 1890's[2,3]. Having failed to find any of these insects myself during one or two visits to this glacier, I was very gratified recently to receive from Mr. R. J. Warburton of Waiho, Westland, several specimens which he had collected and preserved in spirit. Through the kindness of Dr. G. H. Satchell, of the Department of Zoology, University of Otago, these have now been identified, not as worms, but as larvæ, pupæ and one adult, of some species of chironomid fly. Moreover, as Dr. Satchell has remarked, it was only the presence together of larvæ and adult that made identification possible. The family Chironomidae has scarcely been studied at all in New Zealand, only a fraction of the species having as yet been described. Known colloquially as the 'Harlequin fly', they are, it seems, almost ubiquitous, chironomid larvæ being taken from such varied environments as hot springs, from the bottoms of deep lakes, from soil, from dung and from many other moist habitats. Yet here is one which selects glacier ice and melt-water for its temporary home. Douglas[2] had described the "small, worm-like things" as from a sixteenth to an eighth of an inch in length, very active, and when chased tending to dive into the almost invisible holes in the honeycombed ice. In considering them probably to be larvæ he anticipated modern determination.

The specimens kindly sent me by Mr. Warburton were found in small streams of melt-water in the centre of the glacier, either in the water itself or in the actual ice forming the bed and banks of the streams; but the majority of the larvæ were dug out of the ice, while the adult stage, the fly, was found crawling on the ice in the vicinity of the 'worms'. Most specimens seem to be more prevalent in streams which flow through comparatively clean ice. The largest 'colony' which Mr. Warburton came across was at the foot of the main ice fall of the Franz Josef Glacier at about 3,400 ft. Here there were literally hundreds of them in the ice in the bed of melt-water streams, although at the time (9 a.m.) the latter were scarcely flowing owing to the frost. Later, when the volume of water had increased, the 'colony' was found to be greatly reduced in numbers. In fact, it would seem that these creatures must have quite a precarious existence, for increase in volume of water, either from melting or rain (in a district of very high precipitation), must wash away the majority of them. They have not so far been discovered on the neighbouring Fox Glacier, nor on other glaciers of the Southern Alps; and their altitudinal range, on the Franz Josef Glacier, seems to be between about 1,400 ft. and 3,400 ft. The larvæ have been found active in dull weather and in sunshine, and at various hours between 9 a.m. and 3 p.m., from summer through autumn to winter, namely, January to June.

There would certainly seem to be ample scope for further study of this interesting species, and stage of development, of this chironomid fly; not even a name is as yet available for it.

Since I am about to return to England, any correspondence arising out of the above subject should be addressed to me, c/o Clare College, Cambridge.

Maintenance of Adult Mosquito Tissue in a Tissue-Culture Medium

A series of experiments to be reported elsewhere has been performed to discover the nature of egg development in adult female mosquitoes. In the course of the work, a tissue-culture medium was used for suspending extirpated ovaries in various stages of development. This was done to see if development of the isolated ovaries could be induced or continued.

The anautogenous species used were *Aedes hexodontus* Dyar and *Aedes aegypti* (Linnaeus). *Aedes communis* (De Geer), a species of mosquito autogenous in the Churchill, Manitoba, region[1], was also used.

The ovaries were removed from the insects using a sterile technique in the following manner. The adult female mosquito was surface-sterilized by immersion for 2 min. in a 0·5 per cent solution of mercuric chloride in 50 per cent ethyl alcohol. The surface-sterilized insect was transferred to insect Ringer solution[2] and the last abdominal segment grasped with a pair of fine jeweller's forceps, while the thorax and upper abdomen were held with another pair of forceps. The genitalia, spermathecæ, ovaries and gut of the mosquito were stretched from the rest of the abdomen by steadily pulling on the last segment. The ovaries were then broken away from the vagina and separated from the insect. They were placed in a drop of tissue-culture medium on a polished, sterile, cover glass, and this cover glass was inverted over a deep depression slide. Finally, the cover glass was fastened to the slide with hot melted paraffin.

The chemically defined tissue-culture medium was the improved *M*199, now called *M*150, developed by Morgan[3]. This medium is similar to that used for growing monkey kidney for polio vaccine research. In *M*150 the muscle tissue of the ovaries of *Aedes hexodontus* and *Aedes communis* showed contraction for as long as seven days, but no egg development was noted. The muscle tissue of *Aedes aegypti* showed contraction for as long as sixty days in *M*150, but again no development of the ovaries took place. Controls of insect Ringer solution and of *Polyphemus* (Lepidoptera), and *Cynthia* (Lepidoptera) blood permitted muscle movement only for from two to three days; there was no development of the ovaries. No sign of mitosis was noted in any of the tissue-culture preparations, but some migration of the strands of tissue attached to the ovaries was noted along the polished glass surface.

Dr. J. F. Morgan, National Health and Welfare Laboratory, Ottawa, Canada, supplied the tissue-culture medium; Dr. H. A. Schneideman, Department of Zoology, Cornell University, supplied the Lepidoptera blood. The interest and advice of both these colleagues were most helpful.

Polymorphism of Alkyl Sulphate Soaps

ALKYL sulphate soaps $NaSO_4C_nH_{2n+1}$, like the fatty acids and alcohols, may be expected to have a tendency to join together the hydrophylic groups of neighbouring molecules. In the crystalline state, this tendency will lead to sheets of double molecules with stretched chains more or less perpendicular to the sheets. We have measured the corresponding long spacing, using the classical method of copper $K\alpha$ reflexion, at a thin layer of soap on a glass slide, the distance plate to axis in the Muller camera being 10 cm. During the investigation, we saw a paper by Rawlings and Lingafelter[1], who made a complete determination of the unit cells. They found different modifications, the α-form with the smallest water content being the most stable. We have also found this α-modification. Moreover, we succeeded in making all our substances crystallize completely in this modification. This proves the chemical homogeneity (within some per cent) of our substances and their identity with Rawlings and Lingafelter's substances. As we have, however, also found a number of rather stable modifications not mentioned by them, we give here a short account of our procedure.

All our preparations were handled at room temperature in one of the following ways: (*a*) Taking the flaky crystals from the bulk material and pressing or smearing them on the glass slide. In Table 1 the solvent used at the last purification of the bulk material, usually not at room temperature, is given, except for the material from Du Pont, which we did not know. (*b*) Dissolving the crystals in various solvents and evaporating the clear solutions on a glass slide at room temperature. (*c*) Soaking crushed crystals for about an hour in more or less saturated solutions, finally smearing them on the slide. (*d*) Putting the crystals on a slide and wetting them with a drop of solvent in such a way that a superposition of the preceding two cases occurs. (*e*) A subsequent heat treatment was sometimes given by putting the slide in a simple thermostat for some time as indicated in the table.

The X-ray exposure took 5–50 min., the angle of incidence varying continuously from 0° to 12° (or 2° to 6°). Fig. 1 gives an idea of the photographs on which the table is based. The first three orders were always by far the strongest. Of the succeeding orders, either the fourth and fifth or the sixth (and eighth) were the strongest; this is indicated in the table by the signs * and † respectively against the spacing. It is rather difficult to make the surface of the soap and not that of the glass slide coincide with the axis of rotation. A correction was sometimes applied for this.

The columns of Table 1 indicate twelve modifications not given by Rawlings and Lingafelter. With C_8- and C_9-soaps we have found only the α-modification (28·5 and 31·0 A.). In the case of C_{12}-soaps, in

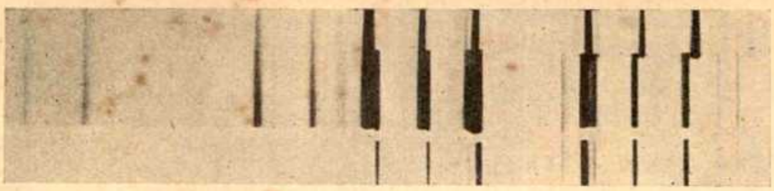

Fig. 1. Reflexion spectra of three layers of C_{16}-soap, marked (1), (3) and (4) in the table. All spectra have been taken on the same plate to allow a better comparison. In the centre left-hand part, the spectra of (1) and (4) have been superposed. The complete correspondence is:

	Left-hand	Right-hand
Upper part	(1)	(1)
Middle part	(1)+(4)	(4)
Lower part	(3)	(3)

Notice the strength of the first three orders and the blurred appearance of the lines of a smeared preparation (1) compared with preparations (3) and (4) crystallized on the slide

addition to the α-modification (38·5 A.) we got a new modification with $d = 32·8$ A. The search in these three cases has, however, not been as exhaustive as with C_{10}-, C_{14}- and C_{16}-soaps.

The different modifications are most probably connected with differences in tilt of the chains and number of water molecules added to the hydrophilic groups. It is less probable that an appreciable number of other solvent molecules were bound, as the same modifications arose from different solvents, which on the other hand always contained some water. It is curious that at room temperature all the modifications found are (meta)stable, as is proved by the constancy of their X-ray diffraction pattern after many days. Another curious fact (see Table 1) is that soaking sometimes has as much effect as recrystallizing: (11), (14), (17) and (21), (25). This may have useful applications.

Low Audio-frequency Electromagnetic Signals of Natural Origin

NATURAL electromagnetic signals of very low frequency have been studied by several investigators during the past few years. In 1948 Willis[1] reported a series of measurements of 'magnetic noise' in the frequency-range 5–800 cycles/sec. but did not discuss the problem of the physical origin of the observed signals. That some of the signals reported by Willis are due to lightning is strongly indicated by observations of other investigators[2]. Aarons and Henissart[3], working in the frequency-range 1–20 cycles/sec., have reported correlations between low-frequency magnetic fluctuations and geomagnetic disturbance and solar phenomena. Therefore it appears that in the frequency-range 1–100 cycles/sec. there is a transition in the dominant physical cause of natural electromagnetic signals.

More than a year ago, we undertook a programme of measurement of natural electromagnetic signals in the audio-frequency range 25–130 cycles/sec. with the view of gathering evidence concerning their physical origin. In March and April of 1954, measurements in the frequency range 10,000–25 cycles/sec., conducted jointly with L. Liebermann of the University of California at La Jolla, established that a large number of signals at less than 130 cycles/sec. were accompanied by a high-frequency component with characteristic atmospheric wave-form, and presumably were produced by lightning discharges.

Subsequent to the joint tests, equipment for measuring low-frequency signals has been maintained by one of us (O. E. D.) in the Borrego Valley of Southern California at lat. 33° 25′ N. and long. 116° 20′ W. At this remote desert location, interference due to artificial signals from electromagnetic devices and power-lines was negligible. Both air-core coils and a vertical antenna have been used for detecting the signals. In both cases the half-power points of the overall system (detecting element and amplifier) were at 25 and 130 cycles/sec. While oscillographic recording has been used for examining signal wave-form, it was expedient to employ a rectifier, smoothing circuit, and pen recorder in the study of the temporal variation of the mean signal amplitude over long intervals, of the order of months.

The mean signal amplitude in the months of March and April exhibited a fairly regular diurnal oscillation which was strikingly similar in amplitude and phase to the diurnal variation of the atmospheric electrical potential gradient measured at sea. Fig. 1 presents the mean diurnal oscillation of the electromagnetic signal amplitude during 14 days in March and April and the mean diurnal oscillation of the potential gradient measured during the months of February, March and April on Cruise VII of the *Carnegie*[4]. Similar correspondence between the two diurnal oscillations was found during the fall months. The maximum ordinates of each curve lie between 14 and 21 hr. universal time. In precisely this interval it is mid-afternoon successively in Central Africa and in the Amazon Valley when these principal world thunderstorm centres reach their peak activity.

The diurnal oscillation of the low-frequency signal amplitude is quite different during the summer

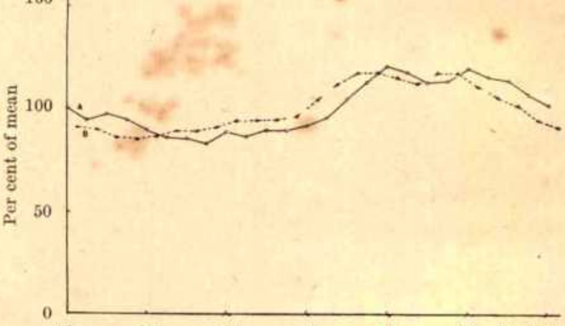

Fig. 1. Mean diurnal variation of (*A*) low-frequency signal amplitude, Borrego Valley, March and April 1954. and (*B*) potential gradient at sea, February, March and April 1929

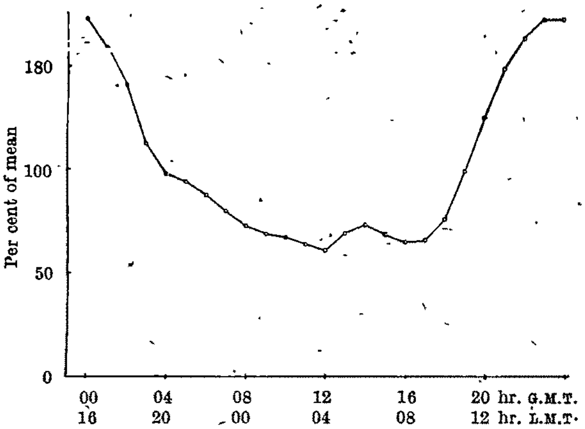

Fig. 2. Mean diurnal variation of low-frequency signal amplitude, Borrego Valley, August 1954

months, as shown in Fig. 2. Between 10 and 24 hr. local (120th meridian) time the amplitude is much larger than during the corresponding hours in spring and autumn, reaching a value about three times as great at 16 hr. local time. The interval of large signal amplitude corresponds to the time of greatest thunderstorm activity on the North American continent, within 35° of the observing station.

It is well known that the electrical potential gradient at sea executes a regular diurnal oscillation on universal time. The observation is usually interpreted as an indication of world-wide thunderstorm activity, on the hypothesis that thunderstorms supply an upward current to the ionosphere which leaks back to the earth in all regions away from the immediate vicinity of the storms. Over the oceans where the atmospheric conductivity varies only a few per cent during an undisturbed day, the potential gradient is nearly proportional to the leakage current density and, hence, approximately proportional to the number of thunderstorms in progress over the world. The implication of the correlation shown in Fig. 1 is that the mean amplitude of the low-frequency electromagnetic signal is also an approximate measure of world thunderstorm activity.

The most surprising feature of the implication lies in the fact that the two principal thunderstorm centres in South America and Africa are respectively 65° and 135° from Borrego Valley; hence, the amplitude of the signals from these centres might be expected to differ significantly. The apparent anomaly finds a plausible explanation if one assumes that the signal power is confined by the spherical wave-guide formed by the earth and ionosphere, and that to a first approximation at very low frequencies one may neglect the differences between signal attenuation over daylight and dark paths. In these circumstances the signal power would vary with angular distance, θ, from the source as $\exp(-\alpha\theta)/\sin\theta$. Assuming the attenuation constant, α, to be of the order of 1/60 deg.$^{-1}$ and taking account of the signal propagation over both the long and short great-circle paths, one finds that the mean signal power from similar sources between 70° and 150° from the observing station varies by less than a factor of 2. Thus, if there is no extensive thunderstorm activity close to the observing station, the mean signal amplitude should be roughly proportional to the number of storms in progress.

While the results presented here are not in themselves conclusive evidence, they strongly suggest that the majority of the electromagnetic signals between 25 and 130 cycles/sec. are atmospherics. Further, the signals in this frequency-range appear to have a sufficiently low attenuation to suggest that they are received from lightning in all parts of the world. In the case of properly selected observing sites, remote from large thunderstorm centres, the mean signal amplitude is roughly proportional to the number of storms in progress. Thus, it appears possible that an index of world thunderstorm activity may be obtained from one or a very small number of carefully selected low-frequency stations.

The measurements reported here have been continued and supplemented by additional measurements. A more complete account will be published elsewhere.

Trinuclear Molecules in the Crystal Structure of Bisacetylacetonenickel(II)

The stereochemistry of four-covalent nickel(II) complexes has been a subject of great interest to chemists for the past two decades. Following the enunciation of Pauling's theories relating stereochemistry, bonding orbitals and magnetic moment, it has been shown that, in all cases where structural studies have been carried out, the diamagnetic four-covalent complexes of nickel(II) are square planar[1]. However, little work has been done to investigate the structure of the paramagnetic (presumably) four-covalent complexes such as bissalicylaldehydenickel(II) and bisacetylacetonenickel(II). These complexes have a magnetic moment indicating two unpaired electrons[2] and usually this has been assumed, without proof, to indicate that $4s4p^3$ tetrahedral bonding occurs. It has been shown by Curtiss, Lyle and Lingafelter[3] that the X-ray powder patterns of bissalicylaldehydenickel(II) and of its zinc analogue are identical. This has been taken as evidence in support of a tetrahedral arrangement of the four oxygen atoms around the nickel(II) atom because zinc(II) is known to display tetrahedral co-ordination. However, in the absence of definite proof that the zinc(II) atom has tetrahedral co-ordination in this instance, the case is not proved. It was decided, therefore, to carry out an X-ray investigation of bisacetylacetonenickel(II) and the preliminary results are summarized here.

Crystals of bisacetylacetonenickel(II), prepared by sublimation under reduced pressure, were found to be orthorhombic with $a = 15{\cdot}65 \pm 0{\cdot}02$ A., $b = 23{\cdot}23 \pm 0{\cdot}04$ A., $c = 9{\cdot}64 \pm 0{\cdot}02$ A. Absent spectra are: $(h0l)$ when h is odd and $(hk0)$ when k is odd. These absences show the space group to be either $Pmab$ or $P2_1ab$. Tests for pyroelectricity and piezoelectricity were negative, and a statistical survey of the intensities of the $(h0l)$ and $(hk0)$ zones by the procedure of Howells, Phillips and Rogers[4] did not give a conclusive result which would enable a choice between the two space groups to be made. The density of the crystals is 1·455 ± 0·001 gm./ml. and the number of formula units $Ni(C_6H_7O_2)_2$ in the unit cell is 12 (calculated 11·96 ± 0·07).

Examination of the three-dimensional Patterson function and, in particular, of Patterson–Harker sections, showed that there are three nickel atoms in the asymmetric unit, the space group being $P2_1ab$. The co-ordinates of these three nickels are given in Table 1; the three atoms are very nearly collinear and the distances between adjacent atoms are: $Ni_1 - Ni_2$, 2·72 A., and $Ni_2 - Ni_3$, 2·88 A.

Table 1. Co-ordinates as Fractions of the Axial Lengths

Atom	x	y	z
Ni_1	0 092	0·036	0 256
Ni_2	0·000	0 120	0 125
Ni_3	−0·098	0·208	−0 017

It is considered that, at the stage to which this work has been taken, the difference between these two values is not significant. The proximity of the nickel atoms implies either (*a*) an interaction between neighbouring nickels, or (*b*) a bridging of neighbouring nickels by other atoms. In either case the crystal must contain large molecules, each three times as big as hitherto supposed, namely, $Ni_3(C_5H_7O_2)_6$. The presence of these trinuclear molecules is shown plainly in the electron density projection on (001), $\rho(xy0)$, reproduced in Fig. 1. Direct and 'trial and error' methods of determining the positions of the other atoms have failed to lead to a unique solution. Many possible molecular models can be ruled out, but with trinuclear molecules the possibility of octahedral co-ordination of the nickel atoms must be taken into account; it is not simply a choice between tetrahedral and square-planar co-ordination.

It is apparent that further investigation of this compound using other physical techniques is essential before one can decide between the various possible structures with any confidence. With this object in view, further work is proceeding in collaboration with Prof. R. S. Nyholm. In particular, the magnetic susceptibility is being studied over a range of temperature, the molecular weight is being determined in various solvents and infra-red studies are to be carried out.

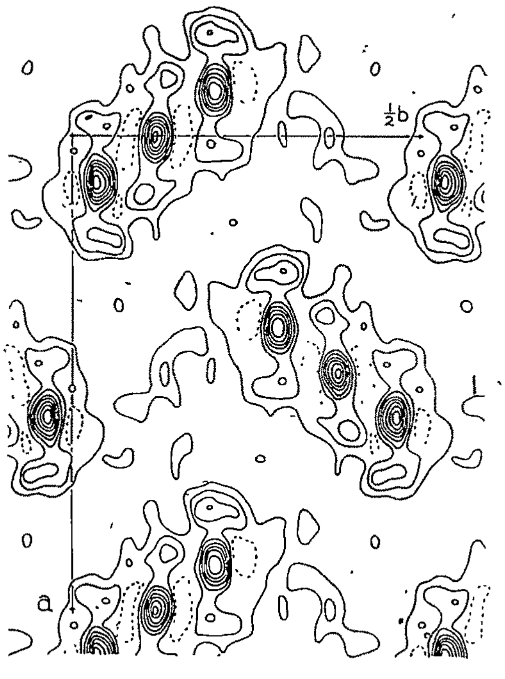

Fig. 1. Electron-density projection on (001). Contour interval arbitrary, some contours around the nickel atoms being omitted for clarity

I wish to thank both Dame Kathleen Lonsdale and Prof. R. S. Nyholm for their help and advice. The award by the University of London of the Arthur Jubber and other postgraduate studentships is acknowledged with thanks.

The Arrow of Time

It is widely believed that all irreversible mechanical processes involve an increase of entropy, and that 'classical' (that is, non-statistical) mechanics, of continuous media as well as of particles, can describe physical processes only in so far as they are reversible in time[1]. This means that a film taken of a classical process should be reversible, in the sense that, if put into a projector with the last picture first, it should again yield a possible classical process.

This is a myth, however, as a trivial counter-example will show. Suppose a film is taken of a large surface of water initially at rest into which a stone is dropped. The reversed film will show contracting circular waves of increasing amplitude. Moreover, immediately behind the highest wave crest, a circular region of undisturbed water will close in towards the centre. This cannot be regarded as a possible classical process. (It would demand a vast number of distant coherent generators of waves the co-ordination of which, to be explicable, would have to be shown, in the film, as originating from one centre. This, however, raises precisely the same difficulty again, if we try to reverse the amended film.)

Thus irreversible classical processes exist. (On the other hand, in statistical mechanics all processes are, in principle, reversible, even if the reversion is highly improbable.) Although the arrow of time is not implied by the fundamental equations, it nevertheless characterizes most solutions. For example, in applying Maxwell's theory, the initial conditions determine whether we choose to work with retarded or with advanced potentials, and the resulting situation is, in general, irreversible.

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S W.7), at 8 30 p.m.—Prof. O. H. K. Spate. "Problems of Development in New Guinea"

Tuesday, March 20

INSTITUTION OF CHEMICAL ENGINEERS (in conjunction with the BRITISH NUCLEAR ENERGY CONFERENCE at the Royal Institution, Albemarle Street, London, W.1), at 5 30 p m.—Mr. C. M. Nicholls, Mr. J. B. Morris and Mr. F. W. Fenning: "The Application of Fluidization Techniques to Nuclear Reactors".

SCIENTIFIC FILM ASSOCIATION (in the Mezzanine Cinema, Shell-Mex House, Strand, London, W.C.2), at 6.30 p.m —Meeting on "The Making of Research Films".*

INSTITUTION OF MECHANICAL ENGINEERS, EDUCATION GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6.45 p.m.—Discussion on "The Use of Pictures and Other Graphical Methods in Teaching Engineering".

ROYAL AERONAUTICAL SOCIETY (at 4 Hamilton Place, London, W 1), at 7 p m.—Mr. P. T. Fink: "Experiments on Flow Over Swept Back Wings".

Tuesday, March 20—Thursday, March 22

INSTITUTION OF NAVAL ARCHITECTS (in the Weir Lecture Hall, 10 Upper Belgrave Street, London, S.W.1), at 10 a.m. daily—Spring Meeting.

Tuesday, March 20

At 10 a.m.—Annual General Meeting.

OIL AND COLOUR CHEMISTS' ASSOCIATION (at the Royal Horticultural Society's New Hall, Greycoat and Elverton Streets, London. S.W.1)—Eighth Technical Exhibition *

Wednesday, March 21

INSTITUTE OF BIOLOGY, LONDON BRANCH; ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION; INSTITUTE OF PHYSICS LONDON AND HOME COUNTIES BRANCH (at the Senate House, University of London, London, W.C.1), at 5 p.m.—Joint Symposium on "The Presentation of Science to the Public".

INSTITUTE OF NAVIGATION (at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 5 p.m.—Meeting on "Developments of the Decca Navigator System".

ROYAL METEOROLOGICAL SOCIETY (at 49 Cromwell Road, London, S.W.7), at 5 p m —Mr. J. K. Bannon and Mr. A Gilchrist: "Variations of Temperature in the Troposphere and Lower Stratosphere"; Mr. E. B. Kraus: (*a*) "Secular Changes of Tropical Rainfall Regimes", (*b*) "Secular Variations of East-Coast Rainfall Regimes".

ROYAL STATISTICAL SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m. —Dr. R. H S. Phillips: "United Kingdom Indices of Wholesale Prices 1949–55".

EUGENICS SOCIETY (at the Royal Society, Burlington House, Piccadilly, London, W 1), at 5 30 p m.—Mr. James H. Renwick: "Linkage in Human Genetics" *

INSTITUTE OF FUEL (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 5.30 p.m.—Mr. P. J. Jackson and Mr. J. M Ward: "Operational Studies of the Relationship between Coal Constituents and Boiler Fouling"; Mr. A. M. Freedman "Full-scale Trials of the Humidification of Combustion Air to Prevent Boiler Fouling"; Mr B. Lees: "An Investigation into the Air-heater Corrosion of Oil-fired Boilers".*

ROYAL INSTITUTION, LIBRARY CIRCLE (at 21 Albemarle Street, London, W.1), at 5.30 p.m.—Mr. K D. C. Vernon: "Finding the Answer".

ROYAL MICROSCOPICAL SOCIETY (at Tavistock House South, Tavistock Square, London, W.C.1), at 5.30 p.m.—Dr. E S. Horning: "Some Anomalies in Endocrine Carcinogenesis"

SOCIETY OF INSTRUMENT TECHNOLOGY (at Manson House, 26 Portland Place, London, W.1), at 7 p m —Mr. J. H Askew: "A Novel Relay Amplifier".

BRITISH PSYCHOLOGICAL SOCIETY, MEDICAL SECTION (at the Medical Society of London, 11 Chandos Street, Cavendish Square, London, W.1), at 8.30 p.m.—Prof. H. J. Eysenck: "Psychological Theories and Psychiatric Practice".

Thursday, March 22

MINISTRY OF EDUCATION (joint meeting with the BRITISH ASSOCIATION FOR COMMERCIAL AND INDUSTRIAL EDUCATION, at the Royal Festival Hall, South Bank, London, S.E.1), at 10.30 a.m —Conference on "The Development of Sandwich Courses".

BIOCHEMICAL SOCIETY (at University College, Gower Street, London, W.C.1), at 10.45 a.m —Annual General Meeting followed by Scientific Papers.

PHYSICAL SOCIETY, ACOUSTICS GROUP (at the Royal Institute of British Architects, 66 Portland Place, London, W.1), at 3 p.m.—Annual General Meeting and Symposium on "Loudspeakers". Lecturers: Dr D. M. Tombs, Mr. P. J. Walker, Mr. F. H. Brittain and Mr. S Kelly.

MINERALOGICAL SOCIETY (at the Royal Entomological Society, 41 Queen's Gate, South Kensington, London, S W.7), at 5 p m.—General Meeting.

INSTITUTE OF REFRIGERATION (at the Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London, S.W.1), at 5.30 p.m. —Mr. R. F. Brown: "Thermodynamic Calculations for Programme Control of a Test Chamber"

ROYAL PHOTOGRAPHIC SOCIETY, SCIENTIFIC AND TECHNICAL GROUP (at 16 Princes Gate, South Kensington, London, S.W.7), at 7 p.m.—Mr. F Pollak: "Masking for Half-Tone".

BRITISH PSYCHOLOGICAL SOCIETY, SOCIAL PSYCHOLOGY SECTION (in the Electrical Lecture Room, University College, Gower Street, London, W.C 1), at 7.30 p.m.—Dr. M. R A. Chance. "The Role of Sexuality in the Social Life of Monkeys" (Film and Paper illustrated by slides).

Thursday, March 22—Friday, March 23

INSTITUTION OF MINING AND METALLURGY (in the Lecture Hall of the Royal Society of Arts, 6 John Adam Street, Adelphi, London, W.C 2)—Symposium on "The Extraction Metallurgy of Some of the Less Common Metals".

Friday, March 23

ROYAL ASTRONOMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.15 p.m.—Discussion of Papers of Geophysical Interest. Chairman. Mr B. C Browne. Speakers: Dr. A. H. Cook, Dr D. I. Gough, Dr. E. R Lapwood and Dr. E. R. Niblett.

ROYAL MICROSCOPICAL SOCIETY (in the New Chemistry Building, King's College, Newcastle-upon-Tyne), at 6 p.m.—Dr. J. R. G. Bradfield: "Electron Microscopical Contributions to the Study of Living Matter".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W 1), at 9 p.m.—Prof. P. M. S. Blackett, F R.S.: "Rock Magnetism and the Movement of Continents".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned.

LECTURER IN BIOLOGICAL CHEMISTRY—The Secretary, The University, Aberdeen (March 24).

LECTURER (with special qualifications in physical chemistry or inorganic chemistry) IN THE DEPARTMENT OF CHEMISTRY—The Registrar, University College, Singleton Park, Swansea (March 24).

CHEMIST OR CHEMICAL ENGINEER (with an honours degree in chemistry or chemical engineering or equivalent qualifications, and preferably with operational research experience in the chemical, metallurgical, or fuel industries) IN THE PRODUCTION CONTROL SECTION of the Operations Branch, for duties which include liaison with works managerial staff on production problems, the analysis of operational data, the planning of programmes and the co-ordination of research and development concerned with existing plants and processes—The Recruitment Officer, United Kingdom Atomic Energy Authority, Industrial Group Headquarters, Risley, near Warrington, quoting Ref. 1319 (March 26).

LECTURER (man or woman, with suitable qualifications in physics) IN SCIENCE, to assist in General Science Courses (including a Supplementary Course for serving teachers)—The Principal, City of Leeds Training College, Beckett Park, Leeds 6 (March 26).

LECTURER (with experience in either experimental or theoretical physics) IN THE DEPARTMENT OF PHYSICS—The Registrar, The University, Liverpool (March 29)

PRINCIPAL SCIENTIFIC OFFICER (with at least a second-class honours degree in metallurgy or equivalent qualification, a good background in the engineering uses of the well-known metals and alloys, and a thorough understanding of modern theories of physical metallurgy) IN THE RESEARCH AND DEVELOPMENT BRANCH, U.K.A E.A., Springfields Works, Salwick, near Preston, Lancashire, to direct a section engaged in physical metallurgy and metallography—The Recruitment Officer, United Kingdom Atomic Energy Authority, Industrial Group Headquarters, Risley, near Warrington, Lancs (March 29).

LECTURER OR ASSISTANT LECTURER IN PSYCHOLOGY—The Secretary, The University, Exeter (March 31).

Senior Technician (with considerable training and experience in animal histology, and a basic knowledge of hæmatology and bacteriology)—The Secretary, Chester Beatty Research Institute, Institute of Cancer Research, Royal Cancer Hospital, Fulham Road, London, S.W.3, quoting "Histology" (March 31).

Lecturer (with qualifications in electronics), and Assistants (with qualifications in experimental physics, theoretical physics or electronics), in the Department of Natural Philosophy—The Secretary, The University, Aberdeen (April 1).

Chemistry Laboratory Superintendent at Makerere College, University College of East Africa—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (April 2).

Mathematician, Scientific Officer grade (preferably with a knowledge of aerodynamics or statistics, together with an interest in physics or engineering) with the Air Ministry, for operational research duties in London—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.96/6A (April 7).

Lecturer or Assistant Lecturer in Applied Mathematics—The Registrar, The University, Leeds 2 (April 9).

Demonstrator (with a good honours degree in physiology or biochemistry) in Physiology—The Registrar, The University, Manchester (April 10)

Imperial Chemical Industries Limited Research Fellows in Bacteriology, Biochemistry, Biomolecular Structure, Botany (Plant Biochemistry and Biophysics), Chemical Engineering, Chemistry, Chemistry of Leather Manufacture, Chemotherapy, Colour Chemistry and Dyeing, Engineering (Civil, Electrical or Mechanical), Fuel and Refractories, Geology (including Geochemistry), Metallurgy, Mining (Selective Flotation and Geophysical Surveying), Pharmacology, Physics, Physiology or Textile Industries (Chemistry of High Polymers (keratin and man-made fibres)), Textile Technology and Wool Textile Engineering—The Registrar, The University, Leeds (April 14).

Lecturer in Physics—The Registrar, The University, Reading (April 14).

Lecturer or Assistant in the Joint Department of Chemical Technology and Chemical Engineering (University of Edinburgh and Heriot Watt College)—The Assistant Secretary, The University, Edinburgh (April 16).

Lecturer (with special qualifications in the chemical aspects of plant physiology, and teaching and research experience) in Botany—The Clerk to the Governors, Chelsea Polytechnic, Manresa Road, London, S.W.3 (April 16).

Assistant Lecturer in the Department of Biochemistry—The Registrar, The University, Liverpool (April 23).

Chair of Pure Mathematics tenable at the Imperial College of Science and Technology—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 25).

Lecturer in Biochemistry at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Sydney, April 30).

Professor of Experimental Physics at the University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, April 30).

Chairs (2) in the Department of Pathology and Microbiology, University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, May 31).

Aerodynamicists and Aero Engineers (with a first- or second-class honours degree in physics, mathematics or engineering, or equivalent qualifications) at a Ministry of Supply Aeroplane and Armament Experimental Establishment, near Amesbury, Wilts, for duties which may include the testing of aircraft, development of test methods, interpretation of test results, and liaison with aircraft constructors—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting C.211/6A/AA.

Agronomist (with a university degree in agriculture, and experience in field experimentation, preferably with tropical crops) in the Department of Agriculture, British Guiana, to initiate and carry out crop and fertilizer trials where soil surveys are being carried out to determine optimum land use—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W 1, quoting BCD.79/30/01.

Biochemist (Basic grade), at the Derbyshire Children's Hospital, to work under the direction of the Group Pathologist and Principal Biochemist—The Group Secretary, No 1 Hospital Management Committee, Babington Lane, Derby.

Chemists (with experience in organic or physical chemistry), for developmental work on the preparation of isotopically labelled compounds, the separation of radioactive isotopes from irradiated materials at high levels of activity, the chemistry of natural radio-elements, and the investigation of radioactive effects in chemical compounds—The Personnel Officer, Radiochemical Centre, United Kingdom Atomic Energy Authority, Amersham, Bucks, quoting Ref. 504.

Editor (with a degree in metallurgy, physics or chemistry, and preferably experience in abstracting, and a knowledge of languages) of *Metallurgical Abstracts*—The Secretary, The Institute of Metals, 4 Grosvenor Gardens, London, S.W.1

English Electric Co., Ltd., Research Fellow in Aeronautics—The Warden, College of Aeronautics, Cranfield, Bletchley, Bucks.

Lecturer (with experience in wind tunnel research) in the Department of Aerodynamics—The Recorder, The College of Aeronautics, Cranfield, Bletchley, Bucks.

Master to teach Physics, if possible to advanced level—The Headmaster, Malvern College, Malvern, Worcs.

Mechanical Engineer or Physicist (with a university degree or equivalent, and some knowledge of statistical techniques in research) in the Research Department, to undertake investigations into the strength of glued joints—The Director, Furniture Development Council, 11 Adelphi Terrace, London, W.C.2.

Physicist, and an Engineer, Assistant Experimental Officer o Experimental Officer grade (with the general certificate of education advanced level (or equivalent), in science subjects, and preferabl some teaching experience), to assist with the laboratory work of th Reactor School, including constructing, maintaining and demonstratin experiments in both physics and engineering—The Establishmen Officer, Atomic Energy Research Establishment, Harwell, Didcot Berks, quoting 511.

Physicist or Chemist (with a first- or second-class honours degre or equivalent in physics or chemistry, and research and developmen experience in the field of high polymers, particularly natural an synthetic rubbers) at the Ministry of Supply Headquarters in London for initiation and progressing of research and development work o rubbers for Service purposes and advising Service Departments o technical applications of rubber, also to maintain an up-to-dat knowledge of, and close contact with, basic research and technologica development at Universities and in industry—The Ministry of Labou and National Service, Technical and Scientific Register (K), 26 Kin Street, London, S.W.1, quoting A.81/6A/AA.

Physicist (with a first- or second-class honours degree or equivalen in physics or chemical engineering) at a Ministry of Supply Establishment at Waltham Abbey, Essex, for research on heat transfer phenomena at very high temperatures—The Ministry of Labour an National Service, Technical and Scientific Register (K), 26 King Stree London, S.W.1, quoting A.94/6A/AA.

Research Associates in Experimental and Theoretica Physics in the Molecular Excitation Group—Dr. R. W. Nicholl Department of Physics, University of Western Ontario, Londo Ontario, Canada.

Research Entomologist (preferably with an honours degree i biology and two years (three for appointment as S.S.O.) postgraduat training, or approved experience in scientific research) at the Wes African Institute for Trypanosomiasis Research, for duties whic include some minor routine work in connexion with the runnin of the Entomological Section of the Institute, and primarily to undertake research upon the behaviour, breeding and longevity of th tsetse fly—The Director of Recruitment, Colonial Office, Sanctuar Buildings, Great Smith Street, London, S.W 1, quoting BCD.197/198/0

Research Fellow (with a good degree in physics) in Instrumen Technology—The Professor of Instrument Technology, Physic Department, Imperial College, London, S.W.7.

Senior Experimental Officer or Experimental Officer (wit at least the general certificate of education, advanced level (or equivalent) in science subjects, or a good knowledge, preferably to degre standard, of physics and/or chemistry, and experience in the field o particle size analysis) in the Particle Size Analysis Section of the Chemical Engineering Division's Analytical Group, to organiz and supervise a section and provide a service of particle size analysi in the sub-sieve range, and to develop, or assist in the developmen of, new methods and instrumental techniques where required—The Establishment Officer, Atomic Energy Research Establishment Harwell, Didcot, Berks, quoting Ref. 514.

Senior Scientific Officer (with a first- or second-class honour degree in electrical engineering or physics, and three years postgraduate experience, and preferably with some experience in any o the following fields: (1) millimicrosecond pulse techniques, (2) missile firing trials or (3) development of missile test instrumentation), t lead a team responsible for the development trials of electrical and electronic equipment for use in weapons—The Senior Recruitmen Officer, Atomic Weapons Research Establishment, Aldermaston Berks, quoting 1059/34.

THE CHEMICAL CONSTITUTION OF NATURAL FATS

by **T. P. HILDITCH,** C.B.E., D.Sc., F.R.I.C., F.R.S.
(Professor Emeritus in the University of Liverpool)
Third Edition—Revised and Enlarged

Size: 10" × 6¼" 664 *pages* 24 *figures* 165 *tables* 95*s. net*

The original edition of this book was the first comprehensive treatment of the fundamental chemistry of fats. The third edition maintains the comprehensive nature of the work, whilst the later investigations which have appeared have enabled the presentation of the subject to be still more complete and precise.

TEMPERATURE

ITS MEASUREMENT AND CONTROL IN SCIENCE AND INDUSTRY
(Volume 2)
Edited by HUGH C. WOLFE
(Head of the Physics Department, Cooper Union School of Engineering)

Size. 9¼" × 6" 467 *pages* *Illustrated* 96*s net.*

This work contains the proceedings of the Third International Symposium on Temperature, sponsored by the American Institute of Physics (for whom it is published), the National Bureau of Standards and the Office of Ordnance Research of the U.S. Army. Twenty-four papers prepared by experts cover significant new developments in the techniques of determining the entire range of temperatures.

37 ESSEX STREET, LONDON, W.C.2

PRECISION BS INSTRUMENTS

Refractometers for Industry and Research

Our well-known standard Abbe type refractometer has a refractive index scale on glass and is read by transmitted light, thus leading to greater convenience in taking measurements and a higher degree of accuracy.

The instrument as illustrated is supplied with degree scale arc and micrometer screw reading directly to 10 seconds, corresponding to a refractive index accuracy within 0.00005. Conversion tables for use with sodium light are supplied.

Full particulars sent on application.

We shall be pleased to demonstrate these instruments and give any advice within our power, if you will call at our Works.

RESEARCH AND DEVELOPMENT IN THE ELECTRICITY SUPPLY INDUSTRY

THE Departmental Committee appointed by the Minister of Fuel and Power in July 1954, under the chairmanship of Sir Edwin Herbert, "to inquire into the organization and efficiency of the electricity supply industry in England and Wales in the light of its working under the Electricity Act, 1947, and to make recommendations"*, had wider terms of reference than that which, under Sir Alexander Fleck's chairmanship, reported last year on the organization of the National Coal Board. Indeed, it is the first comprehensive review of the working of a nationalized industry in Britain and, though its main recommendations are concerned with organization, the report also embraces matters relating to staff, finance, tariffs, research and development, as well as to the powers and duties of the Minister. The Committee approached its task with the sole object in mind of the improvement and welfare of this great industry, and its recommendations are intended to make the nationalized industry work better within the framework of public ownership. None the less, the report is a challenge to constructive thinking, not merely about the electricity supply industry in Britain, but also about the limitations and implications of nationalized industry in general. An important feature is its attempt to lay down criteria by which the efficiency of such an industry can be judged.

The report is thus of no less scientific interest than the Fleck report, for, while there is much common ground in the two reports, the whole approach of the Committee is in welcome contrast to the political prejudice which has bedevilled so much discussion of nationalization, both as regards its application to particular industries and the question of public accountability. The Herbert Committee does not indeed suggest easy criteria; but it does indicate factors, if not principles, which should guide decisions on both issues and which cannot wisely be ignored. It notes, for example, how impossible it is to avoid some political element in the whole structure of the industry, including the price structure of its product, because the amount of capital to be raised depends not upon the attractive power of the industry so much as upon the Government's decision as to how much capital shall be raised on the national credit on its behalf. While there is nothing in the Act which requires the industry to supply electricity on uncommercial terms to any customer or class of customer, or to conduct itself in such a way that it would have to face higher costs than a private business, the Committee considers that the industry is in the same position as any other undertaking borrowing money through the mechanism of the market, provided it sees that the Treasury guarantee is not called upon. The Committee accepts the need for a considerable degree of 'public accountability' in a nationalized industry, but suggests that there is some confusion of thought as to how far this extends to borrowed money.

The Committee approached its task by asking itself five questions. Is the industry making the best use of its man-power and physical resources? Is it making the best use of the capital it raises and the revenue it earns? Are the consumers being properly charged for the services rendered to them? Is the organization of the industry well adapted for securing the best use of capital, man-power and physical assets and for ensuring that proper charges are made to consumers? Is the organization well adapted and the staff sufficiently capable to secure the same ends in future?

The report begins by recording admiration for the zeal shown at all levels of the industry since vesting day. In the opinion of the Committee, the way in which the task of carrying out the amalgamations required was achieved with no friction so far as consumers were concerned, and a minimum of internal friction, reflects great credit on all concerned both in planning and execution. Since vesting day, in face of shortages of capital, man-power and physical assets, the industry has largely overcome the shortage of generating plant, and has gone far towards making good the war arrears of maintenance and reinforcement of distribution systems. It has made substantial technical advances and, at a time when coal has increased in price by 270 per cent and the general cost of living index by 137 per cent, is supplying electricity to consumers at an average price only 30 per cent above that ruling in 1939.

The main question with which the Committee has been concerned is not, however, whether the organization of the industry has served its purpose well in the period since vesting day, but whether it is the best form of organization for the running and development of the industry in the future, now that the initial reorganization has been effected. In particular, since the industry has lost the classical spur to efficiency—the possibility of failure or at least of showing up badly by comparison with others—the Committee was concerned as to whether the forms of control used in the industry are effective in securing that money is not spent on unnecessary projects and that full value for money is obtained out of expenditure on necessary projects. The Committee thinks it is necessary to retain a central authority, but that it is essential to remove from such authority both the executive responsibility for generation and transmission and the present vague general responsibility for the industry as a whole, and also to define clearly the functions to be retained at the centre.

Again, the Committee believes that the industry has a long way to go in the introduction of modern aids to good management. In budgeting, in work-study, in operational research, in incentive wage systems, it is not in the van, and in some respects is lagging, partly because it has been unwilling to face the problem of staff redundancy. The industry must also take very energetic steps to ensure that it attracts and retains an adequate supply of first-rate talent for both technical and managerial posts. Like the Fleck Committee, the Herbert Committee points out that part of the trouble lies in the low level of salaries at the top and in the limited number of independent commands. The advent of nuclear power offers the industry an opportunity of seizing once more the imagination of the young, recruiting talent, grooming it for responsibility, and giving it its head.

---

* Report of the Committee of Inquiry into the Electricity Supply Industry. (Cmd 9672.) Pp. viii+189. (London: H.M. Stationery Office, 1956.) 6s. 6d. net.

These criticisms of structure, delegation, management aids and recruitment are all interlinked; but the very size of the industry and the remoteness of authority tend to lead to loss of morale unless it is built up by positive measures. The Committee rightly observes that the industry requires men as close to the field as possible, technically capable, and leaders with initiative and courage. It requires great names in the future as in the past—great engineers, managers and administrators; and it is clear enough that in the minds of the Herbert Committee the scientists and technologists can be expected to provide such names right at the top.

Beyond these criticisms, the Committee recommends that the Central Electricity Authority should be reconstituted, its responsibility for generation, including the construction and operation of the power stations, grid and super-grid being transferred to a new statutory central electricity generation board. The Authority would then be required, *inter alia*, to approve the general plans of both the generating board and the area boards and any proposal by an area board to construct a generating station, as well as to approve research arrangements and programmes. Its independent powers of scrutiny would place the Authority in a strong position to insist upon proper operational research and work-study and to encourage more attention to utilization research. The Committee visualizes the Authority as a body of men, independent of the boards and their day-to-day actions, but ready to help, to co-ordinate and to stimulate, and providing the Minister with an independent body of expert opinion within the industry capable of the critical scrutiny of finance and development which is now lacking.

One consequence of the passive attitude to redundancy adopted by the present Central Electricity Authority has been that work-study, operational research and investigations into restrictive practices are undertaken by management at all levels without enthusiasm—if they are pursued at all—and the most effective deployment of man-power is never possible. In the context of the development of nuclear power in the coming decades, this would clearly be fatal to efficiency. The nation can only afford the large investment of resources which nuclear power development requires if it is assured of the full benefits not only in the saving of fuel but also of man-power which nuclear energy permits. In urging the industry to adopt a more flexible and realistic attitude towards redundancy, the Committee understates the case when it observes that the national economy may well be damaged if men who are in short supply and may be badly needed elsewhere are retained by an industry which cannot itself fully employ them.

It is a marked feature of this report that such tendencies are kept carefully in mind, and the Committee's recommendations are framed to encourage the necessary flexibility and adaptability. This is noticeably true in its comments on the recruitment and promotion of staff. It has already been noted that the industry needs to face more realistically the problems which changing needs for different grades of man-power arising out of improvements in technique and organization may create from time to time; though curiously enough the Committee does not make the obvious comment that technical education and adequate training after entering the industry could do much to ease such problems, and foster the adaptability which is so important in an era of rapid technological change. Its preoccupation is rather that the industry should make the fullest possible use of the opportunity provided by the construction and operation of nuclear power stations to attract the best type of recruits for its technical and managerial posts. It looks at the industry rather through the eyes of a keen, intelligent, young man with a good engineering degree.

First, it recommends that the industry should urgently review the conditions which are causing well-qualified men of the calibre of potential leaders to turn to other fields, and that it should improve the terms of service, including starting salaries and differentials for graduate trainees. Next, it is disturbed by the attitude of the Central Authority towards the advancement of graduate trainees and its policy on training potential managers of the first rank. Here it recommends a deliberate system of selective training and posting of able young men, so that potential leaders may prove their qualities in successive posts and gain the experience which will fit them for higher management. It challenges the Authority's confidence that under the present arrangements future leaders will automatically be forthcoming, and it would like to see more extensive cross-posting of promising young men between the generation and transmission and distribution sides of the industry.

Like the Fleck Committee, the Herbert Committee attaches great importance to a deliberate policy in this matter; and the recommendations are broadly similar, as they are again in regard to research and development. This is discussed under two headings. First, of utilization research, the Committee challenges the adequacy of the allocation of only 5 per cent of the Central Authority's budget for research on utilization research, and recommends that facilities for this purpose be strengthened and provided with more resources. Because this work may not have such high scientific interest as other parts of the research programme, it is suggested that it has not been adequately supported.

The Committee is also critical of both the scale and organization of research and development within the industry. In 1954–55 expenditure for this purpose was about £700,000, or less than 0·2 per cent of the industry's annual revenue; and the Committee suggests that the industry is relying too largely for technical development and progress on research organizations outside the industry. The expenditure on research includes, in fact, an allocation of £60,000 a year for research in universities and technical colleges and more than £250,000 to co-operating research organizations, chiefly to the British Electrical and Allied Industries Research Association. Estimated expenditure on research for 1955–56 is given as £625,000 at the Authority's headquarters and £850,000 by the divisions or area boards and £270,146 to research associations (including £100,000 to the National Industrial Fuel Efficiency Service).

To determine how far the Committee's criticisms of the scale of research are sound requires a much closer examination than is given in this report, and at least some indication of the lines along which investigations are more profitably pursued within the industry rather than outside, and of the type of problem that is being neglected. The comment that an industry that has to have scientific knowledge pushed at it is never as strong as the industry which is organized to pull it in is fair enough; and the Herbert Committee appears to be disturbed rather with the present attitude to research and with the possibility that the present scale of research does not supply the industry with sufficient men inside scanning the horizon of knowledge and capable of interpreting what they see for its guidance. The Committee is also disturbed at the diffusion of responsibilities for research and development inside the Authority.

The Committee believes that the responsibilities of the Electricity Supply Research Council are much more limited than the Council's terms of reference indicate, and that the present organization established to deal with research and development is inadequate if science is to be put to work and bear fruit in this industry. It urges that in such a technical industry science should be represented at the highest level of management and that, with the exception of utilization research, a full-time member of the proposed generation board should be responsible for research and development, supported by a research staff of high quality. It believes that the area boards should also extend their research activities and be less dependent on the initiative of the electrical manufacturing industry for technical progress and innovations.

There can be no question that the Herbert Committee is right in holding that the electricity supply industry in Britain, by its very nature, should be in the forefront of industries organizing and applying research and development on an extensive scale; and its observations in regard to fuel requirements and nuclear energy indicate one direction in which expansion of that effort is required. It is better, the Committee suggests, for the Authority to build and operate a limited number of nuclear power stations than to wait on developments instituted by other authorities and organizations at home or overseas, and its criticism of the organization being established by the Authority to deal with its nuclear responsibilities reflects this concern. The recommendation that the post of deputy chief engineer, responsible for the construction, operation and development of nuclear stations, be created is reasonable; though there may be need for more attention to what is already being done in the way of research and development by the Atomic Energy Authority than is indicated in this report, bearing in mind the Committee's remark as to the desirability of the Central Electricity Authority being able to meet the Atomic Energy Authority and the manufacturing consortiums at scientific and technological levels on equal terms.

The Herbert report thus goes far to supply the efficiency audit which has often been adumbrated in discussions on the control of nationalized industries and their public accountability; and it is an important contribution to that debate. It indicates factors which are not peculiar to the electricity supply industry, but are valid in respect of accountability or efficiency of any such industry, such as the bearing on efficiency of opening every transaction to public examination and the repercussions of a monopoly, with the absence of alternative employment, on conditions of service and recruitment. Warm appreciation of the achievements of the industry has not prevented frank appraisal of its inherent dangers—and those dangers are not limited to this particular nationalized industry.

The report is also a valuable stimulus to constructive thought about the factors upon which technological progress depends. Even where the Committee's conclusions are accepted with reserve, they indicate none the less the importance of those factors for technical efficiency. No scientist or technologist could wish for a clearer and fairer statement as to the place of research and development in industry, or of the importance of a considered policy for the recruitment and promotion of staff. The need for flexibility and adaptability, for open-mindedness and ability to face the future and to consider the implications of technical change and advance, not merely in terms of finance and economics, but equally in relation to staff and society as a whole, are emphasized at every turn; and they are seen against the background of the nation's limitations in man-power and other resources. There is no shirking of difficult or unpleasant issues; and although the report says relatively little about technical education and the relation of the research organization of the electrical supply industry to that of Britain as a whole, it none the less makes it abundantly plain that any realistic appraisal of expenditure on research must take full account of what is being done by nationalized industries such as this, and of their relations with the Department of Scientific and Industrial Research and the research associations. Last but not least, the report supplies further evidence of the vital importance of an adequate system of education (technical and technological as well as general), if industry is to be supplied with the technicians and general operatives, as well as with scientists and technologists, possessing the adaptability which is so essential in an era of rapid technological development.

RALEIGH'S ATTEMPTED COLONIZATION OF VIRGINIA

The Roanoke Voyages 1584–1590

Documents to illustrate the English voyages to North America under the Patent granted to Walter Raleigh in 1584. Edited by Prof. David Beers Quinn. Vol. 1: pp. xxxv+496. Vol. 2: pp. vi+497–1004. (Works issued by the Hakluyt Society. Second Series, No. 104.) (London: Cambridge University Press, 1955.) 120*s.* net.

In these two most valuable and fascinating volumes Prof. D. B. Quinn has continued for the colonization of Virginia under Raleigh what he had earlier completed for Sir Humphrey Gilbert's ventures in New England and Newfoundland. Spain, through Columbus, discovered the Caribbean lands, and within fifty years or so her empire stretched from California to Tierra del Fuego. Portugal, using Vespucci, coasted Brazil and Argentina and began its colonization in earnest by 1550. But England, which through John Cabot had explored from Greenland to New England, made no attempt to establish a colony in the New World. The Tudor monarchs sensed, almost immediately, that such voyages westward would not lead easily to Cathay and the Spice Islands, and so, apart from the fisheries of Newfoundland, English interest in the Americas lapsed until 1578. Gilbert's warrant to establish colonies in North America lasted from 1578 until 1584, and thereafter Sir Walter Raleigh obtained the Queen's patent to do so, provided he did not interfere with the Newfoundland fisheries.

Hakluyt published many of the main sources for the voyages and colonization of Virginia undertaken between 1584 and 1590. The documents in these two volumes include those of Hakluyt supplemented by many minor documents and new material and interpretations derived from modern scholarship. Vol. 1 includes seventy-three documents dealing with the 1585 and 1586 voyages, while Vol. 2 has thirty-four English documents on the 1587–90 voyages, together with fifty-two Spanish documents, two of them published originally by Miss Wright, which deal with these English voyages to Roanoke Island in Virginia.

The introduction, of seventy-six pages, assesses the material, and at the beginning of each chapter a narrative is given of the events and material in the documents. Footnotes and annotations are most liberal and reveal the thorough and rich scholarship of the editing. Prof. Quinn considers that during 1584–86 the English ventures were not over-publicized, probably because of the danger of Spanish interference. From 1587 onwards, relations with Spain were open war if not official war, and after the defeat of the Armada there was no further fear of Spain. The documents published by Hakluyt were in the nature of propaganda for the colony, and Quinn believes that they suppressed some features of the expeditions to present the project in as attractive a light as possible. He also considers there is evidence to show that Raleigh and Grenville intended to establish a colony at about 36° N., which would be sufficiently north of Florida to avoid Spanish attack yet close enough to the West Indies to provide a base for privateering. It is this potential role of the Virginia colony on Roanoke which led the Spaniards to keep on searching to destroy it from 1590 until 1600, unaware that it had been abandoned in 1590.

The 1584 voyage located Roanoke Island, while Grenville's voyage of 1585 established a fort and colony on it. Lane was left with a garrison, expecting Raleigh to send a relief ship and stores by Easter 1586. It did not come until late June, and by then Lane and the colonists had been taken off by Drake, at their request. Grenville arrived with three hundred men two weeks later to strengthen the colony, but finding it deserted he left a holding party of only eighteen men, who were attacked by Indians and overcome. By such a narrow margin did the fair enterprise of Raleigh's colonization of Virginia fail to succeed: as Quinn notes, "the whole sequence of colonization was destroyed, inadvertently, by Drake". The drawings by White and the maps by White and Hariot, no less than their accurate descriptions of the Indians and the flora and fauna, are historical documents of unique value. There are appendixes on the map of Virginia as it was explored in these expeditions, on Indian words and on the archæology of the settlements. By 1950 the fort made in 1585 on Roanoke was completely reconstructed by Harrington. Sources and indexes of subjects, names and places complete a most comprehensive and brilliant study of this early venture in the origins of the British Empire. Prof. Quinn and the Hakluyt Society are to be warmly congratulated on this absorbing and scholarly addition to their famous series.

Arthur Davies

LUCUBRATORY BIOCHEMISTRY

Biochemistry

An Introductory Textbook. By Prof. Felix Haurowitz. Pp. xvi+485. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1955.) 54*s.* net.

According to the author, this text-book "is designed to form the basis of a one-semester course in biological chemistry intended for seniors and graduate students majoring in bacteriology, botany, chemistry, physiology, or zoology". After an introductory chapter, in which the development and scope of biochemistry, the fundamentals and special fields of the subject, and the literature, are all discussed, chapters are devoted to water and its functions, the mechanism of biochemical reactions, the chemistry and metabolism of carbohydrates, proteins and lipids, nucleic acids, porphyrins, mineral metabolism, enzymes, energy balances and nutrition, and human biochemistry. The balance of the book is different from the sort of volume that is produced for medical students, and includes both structural and dynamic aspects of the subject. It incorporates material on animal, plant and bacterial biochemistry.

Since the book is meant for seniors and graduate students it would seem all the more important that it should be accurate in detail, with an adequate discussion of the evidence on which the accepted ideas about metabolic processes are based. To produce a book for graduate students in a subject which is developing as rapidly as biochemistry advances to-day is a problem to be faced by all careful writers with some alarm and with intense care for detail and form. Dr. Haurowitz's book reveals little evidence of his awareness of these needs. Although the book is meant for seniors, references to original publications are not given in most instances. Such references as are included are largely to books and to review articles. One would hope that the senior student would have the time and stimulus to read at least a few original papers. In a number of instances Dr. Haurowitz includes a reference to a publication appearing in 1955 without documentation. For example, the section on p. 240 dealing with "Acetalphospholipids" includes the undocumented reference, "Klenk, 1955". One reader of this paragraph at any rate is left with complete bewilderment as to what Dr. Haurowitz means to say, and if indeed he intended to give an account of Klenk's interesting findings published in *Hoppe-Seyler's Zeitschrift* (299, 66–73 ; 1955) about acetalphospholipids and plasmalogens, he could have done so quite easily. References are also made in a number of cases to the possible role of hydride ions ($H:^-$) in the reduction of certain coenzymes ; but no references to the literature are given. On p. 386 the reader is told that as the result of studies with deuterium there is evidence that diphosphopyridinenucleotide and triphosphopyridinenucleotide accept hydrogen directly from substrates, and that if protons were transferred they would suffer exchange with the hydrogen ions of the solvent, a possibility ruled out on experimental evidence. Yet in numerous places the transfer is depicted as involving protons together with electrons, and occasional references are made to hydride ions. The discussion on p. 387 of the mechanism of action of alcohol dehydrogenase and acetaldehyde dehydrogenase is likely to confuse any critical student.

The text contains many misstatements, contradictions and unjustified generalizations, of which some will be quoted. On p. 42 we are told that "the compounds containing high-energy phosphate bonds are *unstable substances* [author's italics] readily hydrolyzed by water". According to p. 55, "transacetylase" and "acetokinase" are different names for the same enzyme. But this is not the enzyme for which the name "actokinase" was introduced by Ochoa and his colleagues (*J. Biol. Chem.*, 211, 737 ; 1954). On p. 64 occurs the interesting statement, "Natural isotopes are stable. . . . In contrast to the radioactive isotopes the natural isotopes are stable and do not emit damaging radiation. However, their determination requires a mass spectrometer which is an extremely expensive piece of equipment". Has Dr. Haurowitz never heard of naturally occurring radioactive isotopes, for example of potassium or of carbon ? From p. 78 we learn that "like all substances with asymmetric carbon atoms, the sugars are optically active". The intelligent student who has already learned about internal compensation will be puzzled by this. On p. 124 under the heading "Ketogenesis" occurs the following statement : "If carbohydrates are withdrawn from the food of diabetic patients, both hyperglycæmia as well as glycosuria disappear. However, another serious disturbance arises due to the formation of large amounts of acetoacetic acid CH_3—CO—CH_2—COOH, β-hydroxybutyric acid CH_3—CHOH—CH_2—COOH, and acetone CH_3—CO—CH_3. . . . Clearly, the diabetic patient oscillates between the two dangerous symptoms of glycosuria on the one hand and acidosis on the other. Both are relieved by insulin". Physicians who at one time treated diabetes by the administration of a diet rich in fat and who reduced diabetic ketosis by undernutrition or starvation would be most interested in this passage. On p. 132 the statement is made, "The amino acids are colorless substances that are soluble in water", although later the insolubility of cystine in water is mentioned (p. 156). According to p. 154, "Since arginine is formed from ornithine and ornithine from glutamic acid through its semialdehyde (see p. 150), arginine synthesis is a slow reaction which sometimes is not rapid enough to provide for the arginine requirements of the organism. Arginine is, therefore, one of the amino acids which are nonessential for some animals such as dogs, but essential for others such as chicks". That any modern biochemist should accept the validity of this sort of argument is astonishing. On p. 155 we are told : "In the muscle of invertebrates, which is free of creatine phosphate, its role of phosphate donor is taken over by arginine phosphate". Any generalization of this sort is dangerous in view of the existence of some invertebrates in which both creatine phosphate and another phosphagen are found (Baldwin, "An Introduction to Comparative Biochemistry", p. 74 ; Cambridge University Press, 1948 ; Baldwin and Yudkin, *Proc. Roy. Soc.*, B, 136, 614 ; 1950). P. 273 carries the following statement : "The low concentration of the hormones in the sex glands was primarily responsible for the failure of previous workers to isolate the hormones from the glands. Evidently the hormones are rapidly excreted into the urine. Urine in contrast to the organs, contains only small amounts of other lipids ; therefore the urinary benzene extract contains relatively uncontaminated hormones". After this astonishing dictum the incorrect numbering of the sterol skeleton on p. 265 seems to matter less. On p. 279 the formulæ for corticosterone and other adrenal steroids are also incorrect. On p. 276 we are told that "Attempts to prepare estrogenic hormones synthetically, led to the unexpected result that certain *stilbene derivatives*, [author's italics] such as dihydroxydiethylstilbene, are just as active as estradiol". That is historically incorrect, as can be seen by consulting the early papers of Dodds and his collaborators. Likewise, the statement on p. 277, that one of the simplest substances with estrogenic activity is 4-hydroxyphenylpropene, is wrong (see, for example, Lawson, *J. Chem. Soc.*, 4696 ; 1954). On p. 287, the following two sentences appear not far apart : "The high surface activity of soaps and of proteins is responsible for their ability to form foams". "The surface activity of the octyl alcohol molecules is much higher than that of proteins so that they displace the proteins from the water surface and the formation of the froth is prevented". A paradox indeed ! On p. 415 occurs the statement, "Owing to their insolubility in water and in the digestive juices, fats and oils are more slowly digested than carbohydrates and proteins. For this reason, fats are not the most efficient source of energy, although they can be used for this purpose as mentioned in the preceding paragraph". What does this mean ? Examples of this sort could be added to considerably ; but enough has been said to indicate the general flavour of the book and of the writing it contains.

The balance of the book is unusual. A very large amount of space is devoted to the chemistry and physical chemistry of proteins, and a picture of a Langmuir film balance is included on p. 287. The statement about the tricarboxylic acid cycle on pp. 59–61 is a category of the reactions involved, with the promise that details of the cycle and the chemical nature of its members "will be discussed later (pp. 249 and 119)". Unfortunately, we are nowhere given a discussion of the evidence from which the existence of the cycle and other metabolic pathways have been deduced by Szent-Györgyi, Krebs, Ochoa and many others, and this surely could have been included at the expense of some of the space devoted, for example, to alkaloids (pp. 177–180) or to terpenes (pp. 255–257).

A critical and accurate text-book of biochemistry for postgraduate students is needed which is not written with a medical point of view in mind and which includes both dynamic and static aspects of the subject within a reasonable size. Dr. Haurowitz has had the courage and tenacity of purpose to attempt this important task, and the 485 pages of his book might have provided such a volume. Unfortunately, they have failed to do so.

F. G. YOUNG

NORTH-AMERICAN PLANT TAXONOMY

An Introduction to Plant Taxonomy

By George H. M. Lawrence. Pp. viii+179. (New York and London: The Macmillan Company, 1955.) 23*s*. net.

THIS little book consists largely of a somewhat curious selection of material from "The Taxonomy of Vascular Plants" by the same author. According to the preface, it "is intended to serve as an aid to the non-taxonomist in the use of a manual or flora that accounts for the plants of any region of North America". A brief introductory chapter explains the nature and significance of taxonomy and distinguishes clearly between classification and nomenclature, two things which are frequently confused by the beginner. The survey of systems of classification, which occupies a dozen pages, seems of rather doubtful value to the non-taxonomist who simply wishes to use a flora. Engler's system is criticized once again for its lack of phylogenetic truth, in spite of the fact that it is admittedly based on artificial grades of perianth complexity and that its author never claimed any phylogenetic significance for it.

Nearly one-third of the book is occupied by what is in effect an elaborate illustrated glossary of the terms which may be used in describing vascular cryptogams and seed plants. The illustrations, though generally clear and helpful, are not uniformly accurate; for example, the fern sporangium (Fig. 8*f*) is shown with a stalk which bears no resemblance to reality. A more important point, however, is the great number of terms which are defined. These alone seem enough to discourage any non-taxonomist from attempting to use a flora, and many of them, in my opinion, are unnecessary words which, anyhow, are very rarely met with in modern works. The tendency nowadays is to reduce the number of terms used in description, even if it means a slight loss of precision or the substitution of a rather longer phrase in plain English. The greater precision which might be supposed to be obtained by using a word such as velutinous is largely illusory. The non-taxonomist will neither remember nor bother to look up afresh the precise meaning of such words, while specialists frequently differ over the exact application of the multitudinous terms used to describe qualitative features.

As long as botany consisted essentially of the systematics of flowering plants, this great abundance of descriptive words was all part of the game, but this period in the development of the science ended more than half a century ago. Taxonomists to-day need to make their work readily available to ecologists, physiologists and indeed to every kind of botanist, as well as to the host of happy amateurs. It is high time that many of these esoteric words were forgotten. It seems, therefore, regrettable that thirty-nine words describing hairiness and no fewer than sixty-two describing the shapes of leaves or parts of leaves are defined.

It is difficult to see how the summary of the International Code of Nomenclature or the brief account of phylogeny and biosystematics can help the kind of reader referred to in the preface, though the few pages dealing with collecting and identifying may well be of value to the beginner, and the chapter on taxonomy in North America is of interest to the historically minded.

The remainder of the book deals with important families (of flowering plants) in a rather chatty way. The same kind of information is to be found in more detail and more concisely expressed in most floras. Finally, it is perhaps worth pointing out that the cost per page seems to be about twice as much as that of comparable books printed in Britain.

T. G. TUTIN

NEWER TECHNIQUES IN ORGANIC ANALYSIS

Organic Analysis

Edited by John Mitchell, Jr., I. M. Kolthoff, E. S. Proskauer and A. Weissberger. Volume 2. Pp. viii+372. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1954.) 8.50 dollars.

THE first volume of this work presented methods for the quantitative determination of a number of organic functional groups. The opening chapters of this second volume describe further specific determinations of the carboxyl group, the ester group, the nitro, nitroso and nitrate groups and of total nitrogen by the standard methods. The fourth chapter deals with the uses of lithium aluminium hydride in analysis. One application is to the determination of active hydrogen, and this provides an alternative to the Zerewitnoff method. Lithium aluminium hydride is so powerful as a reducing agent that its action upon various oxygen-containing groups is non-selective. However, the amount of the reagent consumed is proportional to the oxygen present in the groups attacked, and a method has been developed, using an indicator such as N-phenylaminoazobenzene, which gives a direct titration of the number of oxygen atoms present in a compound (ether oxygens being excepted). Great care is necessary to exclude moisture, oxygen and carbon dioxide; but the method should be very valuable.

The remaining five chapters of the book are concerned with special techniques. An account of coulometric methods does not open up many possibilities of their use in organic work. A chapter on polarography shows in detail the many pitfalls and difficulties which may arise with organic substances. Polarographic methods are rapid and convenient in certain instances, but great care and attention to detail are essential. A discussion of methods based on reaction-rate is of considerable interest, but their applicability would seem to be rather restricted. The most important field is probably that of enzyme and microbiological reactions, in which recent development has been rapid, but in this direction the account is disappointing.

A chapter entitled "Phase-Solubility Analysis" deals with tests for purity and the determination of impurities by precise solubility measurements. These methods are sound in principle, but are often very time-consuming. They have proved particularly valuable in the examination of some biological products where the criterion of melting-point is not available. The concluding section on "Countercurrent Distribution" is concerned with a method of highly organized multiple-solvent extraction. Convenient devices for carrying out many successive partitions systematically are described, and the theory of the fate of solutes present is worked out in detail. This technique has been developed largely by Dr. L. C. Craig and has been applied to the separation of acids, fats, bile constituents and protein degradation products.

The articles in this volume have been written by experts and they are in general well documented. It is not a serious disadvantage that some of the methods discussed have a restricted field of application. The production of the book is excellent, and the two volumes taken together will be of real value to the practical organic chemist. G. M. BENNETT

BIRDS OF THE KATHIAWAR PENINSULA, INDIA

Birds of Saurashtra—India, With Additional Notes on the Birds of Kutch and Gujerat

By R. S. Dharmakumarsinhji. Pp. liii+561+51 plates (33 colour). (Bombay: N. M. Tripathi, Ltd., 1955.) Rs. 50; 112*s*. 6*d*.; 18 dollars.

UNTIL twenty years ago, nearly all the works on Indian birds came from British pens. Then Salim Ali's books began to appear, which rank with the best of any previously published. Now, other Indian authors are following him, and the present volume, written by the brother of the Maharajah of Bhavnagar, and sumptuously produced, is an impressive addition to Indian ornithological publications. Saurashtra is the part of India which lies between the Gulf of Cambay and the Arabian Sea. It appears as Kathiawar on most maps, but Saurashtra is the older name. It is, therefore, a conveniently compact area for field-work. It contains no mountains more than four thousand feet high, and is mostly hilly and undulating. But there is a good deal of salt land and semi-desert (though the rainfall is locally heavy), so that rare or very local species, such as the great Indian bustard, its congener the florican and some of the sand-grouse, breed in fair numbers.

The author writes that he began his observations on birds when he was a schoolboy in England; but the whole of his adult life has been spent in Saurashtra, and this book is a remarkable testimony to the assiduity and care with which he has studied birds, with no neighbour to assist, throughout the years. The book is so full of first-hand and first-rate bird lore that it is not easy to comment on any special passages in a short review. The author is an expert on the eagles, which are among the most difficult birds to distinguish, and his field-notes on their sight-identity are of special value after the recent appearance of some misleading information on some of the same species from Russian ornithologists.

In some cases, rather fuller information would have been desirable. Thus, both the roller (*Coracias garrulus*) and the spotted flycatcher, which occur in this part of India in some numbers on the autumn migration, are claimed as winter visitors. The impression hitherto has been that neither species remains in India during the winter, and it has been assumed that they migrate some fifteen hundred miles across the sea to Africa. It is a pity that the author does not give his evidence in these and some other cases in more detail than a general statement.

The book is fully illustrated, with photographs, many of them taken by the author, and with coloured plates by an Indian artist, Somalal Shah. These plates are variable in quality. The larger birds are often felicitously shown; but the smaller birds look as if they had been based on mouldy skins, and fail to give the distinctive features. However, the book is an important addition to the knowledge of Indian bird-life. H. G. ALEXANDER

ANTIQUITIES IN BRITAIN

Buried London

Mithras to the Middle Ages. By William Thomson Hill. Pp. 192+40 plates+14 maps. (London: Phoenix House, Ltd., 1955.) 25*s*. net.

Furniture in Roman Britain

By Joan Liversidge. Pp. viii+76+69 plates. (London: Alec Tiranti, Ltd., 1955.) 10*s*. 6*d*. net.

MR. THOMSON HILL's book came in on the crest of the wave of public interest which broke—for reasons that are still not altogether clear—on the discoveries which were made in the Walbrook area of London in 1954. "Buried London" is essentially an expansion of newspaper articles dealing with current work in the bombed areas and with the very serious losses to the visible antiquities and historic monuments of the city which resulted from the bombing during the Second World War.

The book is not a scholar's book and the phrase "complete record" in the publisher's note should be read with the reserve appropriate to such declarations. The "complete record" cannot be made until the present phase of recovery of evidence (against time-limits) has ended, to release the energies of the small group of archæologists engaged for the next stage. In its primary form at least, the "complete record" must follow a very different pattern from that presented here.

The present popular enthusiasm for archæology has, inevitably, its good and its bad points. There is a strong element of irony in a situation which creates an earth-shaking sensation out of a discovery like that of the Walbrook Mithræum, in which (important as it was) there was a strong element of luck, while persistently ignoring results of equal historical significance the winning of which called for much greater application and technical resource. But that is how the world wags, and archæologists are not the only sufferers. Unlike most of his professional colleagues, Mr. Thomson Hill has tried to see his subject whole; but too often it has defeated him, and there are some surprising and sometimes serious mistakes.

"Furniture in Roman Times" is written for the general reader, but draws conveniently together for the student a mass of otherwise widely scattered material. Inevitably the amount of Roman furniture actually surviving in Britain is small: it would be even smaller were it not for the use that was made of Kimmeridge shale, a material only less perishable than timber. It is interesting to observe how the long-established Kimmeridge industry adapted itself to the imported classical style as yet another element in the uniform upper crust of material culture beneath which, at least in some parts of the Empire, a native non-Roman element often persisted.

Contemporary sculptures, on tomb-monuments particularly, augment and elucidate the fragments: sometimes conventionally as in the Chester series, sometimes more vividly as in the Simpelveld sarcophagus or the Toilet Scene from Trier. The final impression is that, technical skill and ingenuity apart, Roman furniture was not particularly beautiful and only a liberal use of soft furnishings could have made it comfortable. But as Prof. J. M. C. Toynbee has pointed out in her introduction, studies of this sort make the past live—and that not only for the general reader. For archæology not merely extends knowledge of man backwards in time; it also deepens and enriches understanding by the light that it sheds on aspects of his life that 'history' may fail to touch.

W. F. GRIMES

HEAT AND MASS TRANSFER IN COMBUSTION THEORY

Some Fundamentals of Combustion

By Dr. D. B. Spalding. (Gas Turbine Series—Vol. 2.) Pp. x+250. (London: Butterworths Scientific Publications; New York: Academic Press, Ltd., 1955.) 40s. net.

THE first of a series of volumes, edited by J. Hodge, of Power Jets, and describing various features of the gas turbine has already been published. The volume under review is the second of the series, and its author, Dr. D. B. Spalding, is reader in applied heat at the Imperial College of Science and Technology, London. The science, though not the subject, of combustion is a relatively new one. Prior to 1939 work had been concentrated on a limited field, concerned with the combustion of premixed gases in the petrol engine, and especially with the phenomenon of detonation, the principal obstacle to progress in the prime mover then of supreme importance in military and commercial applications. A stage had been reached when it appeared that further advances must be made by the chemist rather than by the engineer.

With the increased use of the diesel engine, the rise in cost of fuel and the advent of the gas turbine, the field of combustion research has greatly widened, while detonation has ceased to be of much importance compared with, for example, the necessity for producing high combustion intensity, or with flame stabilization and blow-out criteria. Consequently, a very large literature has grown up; but except to the specialist, difficulty is experienced in reading and interpreting results which the various kinds of authors—engineers, physicists and chemists—present with widely differing emphasis. In this book Dr. Spalding has set out to integrate the most important results of recent research, including a substantial contribution from his own work accomplished while he was at the Department of Engineering, Cambridge, and has in fact succeeded in developing a theory which combines the many isolated fragments of combustion research into a unified whole.

The first two chapters serve as an introduction to thermodynamics and fluid flow, but a serious student of combustion will require a much fuller explanation than is here contained. However, the clearly described and elaborate compressible-flow chart must be of interest to all concerned with high-speed flow of gases, while the thermodynamic approach is clear and rigid. It is, however, in the presentation in the next two chapters of the subjects of heat and mass transfer that the greatest originality lies. Here are developed the differential equations governing heat and mass transfer in the most general cases, such as when chemical reaction is also present. The solution of these equations is not usually possible; but by modifying Fick's Law so that it may be expressed in terms of concentration gradients instead of partial pressures and, when necessary, by assuming that thermal and mass diffusivities are equal, considerable simplification is achieved, so that in some special cases the equations can be solved and in general the form of the solution be derived, in functions of dimensionless groups (just as in heat transfer the Nusselt number is expressed as a function of the Reynolds and Prandtl numbers). It is shown that, with such simplifications, in all cases of mass transfer the results can be expressed in terms of the Reynolds, Schmidt and a new dimensionless number called the transfer number, which may have various simple forms according to the specific problem. The use of the transfer number is fundamental since it shows the different applications considered (for example, vaporization at liquid surfaces, combustion in gas jets and from solid and liquid fuels) to be special cases of a unified whole. The approximations involved are bold, but the quantitative results achieved are well within the usual limits of error associated with problems involving a multiplicity of variables, and lead to a clear conception of the controlling factors of each problem.

Chapter 5 is devoted to combustion processes in which the time-rate is important. There are excellent discussions of the propagation of flames in premixed gases, the conditions for flame extinction, flame stabilization and the criteria for blow-out conditions. The chapter is entitled "Chemical Effects in Combustion", somewhat misleadingly, as the properties discussed are much more physical than chemical. Conclusions developed from the theory are drawn in the short last chapter where there is some interesting criticism of the design of combustion chamber elements. There is no description of practical applications, as a further volume entitled "Combustion Practice" is scheduled to appear in the series.

All in all, this is an excellent book for every worker in combustion research, though its appeal to the practising engineer is much less. The style is crisp and authoritative, the references full, and the author is to be congratulated upon the lucid manner in which he interprets the rather bewildering array of non-dimensional numbers that confronts the student in this subject. He makes their use seem apparent and inevitable, and by their aid brings a hitherto not apparent coherence to a rather untidy subject.

F. D. ROBINSON

Asiatic Magnolias in Cultivation

By G. H. Johnstone. Pp. 155+34 plates. (London: Royal Horticultural Society, 1955.) 63*s*.

THE author of this work brings to his task not only a love of magnolias, but also a long experience of their culture, and it is particularly where his knowledge of them as living entities illumines the text that the horticulturist will find the pages especially worth perusal. In the first two chapters, where cultivation, pruning and propagation are treated, Mr. G. H. Johnstone has brought together the experience of others, enriched by his own, to provide a helpful guide to any who would essay the cultivation of this genus. The remainder of the text deals with the species individually. Of some forty-five known magnolias, exclusive of hybrids, the Asiatic species, which are here considered, number eighteen, and nine of these latter and their varieties are admirably portrayed in the fourteen coloured plates, mostly from paintings by Miss A. V. Webster.

For each species a diagnosis and formal description is provided, together with a more discursive consideration of matters of identity, culture and other aspects which will appeal especially to those who themselves share Mr. Johnstone's enthusiasm for growing magnolias. They range from tall trees such as the magnificent pink-flowered *M. campbellii* from the Himalayas or *M. obovata* from Japan, to shrubs such as the charming *M. sinensis* from China, with its exquisite drooping flowers and crimson stamens. The flowering period extends from the bleak days of March, when the white stars of *M. stellata* burst through their furry covering, to August and September, when *M. sieboldii* and *M. delavayi* contribute to the garden's fragrance as well as to its beauty.

Many species are diploid, with 38 chromosomes; but the members of the Yulania section, to which the beautiful *M. denudata* introduced from east China by Banks in 1780 belongs, are all hexaploids with 114 chromosomes, while the Chinese *M. liliflora* is a tetraploid with 76 chromosomes. The genus, in fact, presents a great diversity of interest to the student of plant life, and æsthetic attraction and problems of cultural skill to the grower, so that those who peruse this volume should feel indebted to Mr. Johnstone for its production and to the Royal Horticultural Society for its publication at what, in these days, must be regarded as a very reasonable price.

E. J. SALISBURY

Scientific and Technical Societies of the United States and Canada

Part 1: Scientific and Technical Societies of the United States. Compiled by the Library, National Academy of Sciences—National Research Council. Part 2: Scientific and Technical Societies of Canada. Compiled by John R. Kohr, National Research Council, Canada. Sixth edition. (Publication 369.) Pp. 447. (Washington, D.C.: National Academy of Sciences—National Research Council, 1955.) n.p.

BLESSED with vast rich natural resources, the North American people have not been slow to develop an economic system that seems naturally adapted to the rapid exploitation and enjoyment of these resources and a high standard of scientific and technological achievement that is both the outcome of economic growth and the means by which further and swifter advances are made. Probably no other people are more scientifically minded, and an indication of this is given by the present edition (the sixth) of the "Handbook of Scientific and Technical Societies of the United States and Canada".

As is remarked in the preface, during the twenty-seven years since the first edition, a large number of new scientific and technical organizations have been started in North America, and though they may be concerned with highly specialized topics and their membership small, the fact of their establishment is worth recording. Glancing over the pages, the reader is impressed both by the very large number of regions or localities that are associated with a particular organization and by the great wealth of topics that form the basis of the various organizations.

It is to be noted, too, that the earlier editions of this handbook covered both societies and institutions; but the latter are now omitted, as also are such other organizations as trade associations with research activities.

There are 1,506 entries for the United States and 206 for Canada, occupying more than four hundred pages. The size and content of the entries vary somewhat; but typical of the details given are the history of the society, its purpose, membership, meetings, library, research funds and medals, etc., and publications. The two indexes, one for the United States and one for Canada, are of the omnibus type: they include a subject classification of the activities, purposes and research funds of the societies (with the subjects appearing in capitals); periodicals (in italics); names of research funds, prizes, medals, etc., and changes in names of societies after 1948. The book is prepared jointly by the National Academy of Sciences—National Research Council of the United States and by the National Research Council of Canada. As such it bears the stamp of authority and can be relied upon.

The Chemistry and Fertility of Sea Waters

By Dr. H. W. Harvey. Pp. viii+224. (Cambridge: At the University Press, 1955.) 30s. net.

THIS excellent book deals more fully with the fertility of sea water than did its predecessor, "Recent Advances in the Chemistry and Biology of Sea Water" (Cambridge, 1945). Dr. H. W. Harvey recognizes five major processes, which in his unsemantic way he calls "conditions". Briefly they are: illumination; replenishment of nutrient salts; grazing of plants by animals; removal of plants from the upper, photosynthetic, layer of the sea by turbulence; and metabolism, which is at least partly governed by temperature. Chapter 5 collects and sets out succinctly the published effects of those processes on the growth of the plants in the plankton. A shorter chapter suffices for what is known about the production of animals. The two chapters together mark a notable advance in elaboration of knowledge, compared with that behind Chapter 10 of the preceding book—worth, with the better paper and printing, the extra cost.

The new book also gives more information on the chemistry, including how to determine phosphate much more accurately than has sufficed hitherto, and therefore less rapidly. Other additions on chemical methods are perhaps more useful, and all are described more precisely than in the earlier books. Harvey's study of sea water and the related biology forms an essential part of twentieth-century oceanography, and chemists may care to note this advance in their own subject in an unusual field.

MICHAEL GRAHAM

Optical Properties of Thin Solid Films

By Dr. O. S. Heavens. Pp. vii+261. (London: Butterworths Scientific Publications; New York: Academic Press, Inc., 1955.) 35*s.* net.

WITHIN recent years the interest in the field of optical properties of thin solid films has been greatly stimulated and many papers have been published, due largely to the development in the methods of preparing thin films and their examination by optical and electron-microscopic techniques. Consequently, a large amount of information about the nature and behaviour of thin films and their optical properties has become available. Dr. O. S. Heavens's book is therefore a timely and welcome addition to the existing literature.

There are seven chapters, including the introduction. The second chapter is devoted to the techniques for the production of films, with special emphasis on the evaporation method which is so commonly employed these days. The next chapter briefly describes the structure of solid films as revealed by electron-optical studies. The fourth chapter is devoted to the calculation of the optical properties of thin films, namely, the reflexion-transmission coefficients and phase changes at a single film or a system of layers. This chapter will be specially welcomed by those who are starting work in the field and want to have a connected account for their calculations. In the next two chapters are given a discussion of the methods for the measurement of optical constants and thickness of the film, followed by a general survey of the results obtained. Many interesting applications of thin films in the laboratory and industry are covered in the last chapter.

The subject-matter of the book has been well arranged and is presented in a very clear style. Each chapter is followed by a list of references to the original papers. The book will be of use both to the research worker studying optical properties of thin films and those engaged in industry.

Reagent Chemicals and Standards, with Methods of Testing and Assaying Them

Also the Preparation and Standardization of Volumetric Solutions and Extensive Tables of Equivalents. By Joseph Rosin. Third edition. Pp. x+561. (New York: D. Van Nostrand Company, Inc.; London: Macmillan and Co., Ltd., 1955.) 70*s.* net.

THE author of this book, formerly chief chemist and chemical director of Merck and Co., has had considerable experience of the testing of chemical reagents and is an expert in the field. In view of the rapid advances in analytical chemistry during recent years, some forty-five new reagents and solvents have been added to this edition. In each entry the physical properties and standards of the substance are given, and the methods used in testing for impurities and, in many cases, for assay are set out in satisfactory detail. Since the standards are now exacting, sensitive methods involving new reagents are often necessary, and it would be hard to find these in the literature. Some references to recent publications are given.

The book is a valuable storehouse of information which should be available in every chemical laboratory. Manufacturers of chemicals should in particular find it of great service in their laboratories; but it has a wider field of usefulness, since in preparative and research work the purity of the materials is often essential, and the methods of testing for traces of likely impurities should be at hand. In the case of substances used as standards in volumetric analysis, the best methods of assay are given. Indicators and solvents are included.

There seem to be scarcely any inaccuracies in the book, which covers in detail a wide field; but 'dithionate' on p. 413 should be 'dithionite', and the name Kolthoff is given incorrectly on p. 498. This is a sound and informative book which will be welcomed by all chemists. The paper, printing and binding are excellent.

Modern Gas Analysis

By Paul W. Mullen. (Interscience Manuals.) Pp. ix+354. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1955.) 5.50 dollars.

ABOUT two-thirds of this pocket-sized book are devoted to conventional absorptiometric methods of gas analysis, and the remainder to instrumental methods. It thus provides a wide survey of current practice; but the second part in particular is brief, and more information would be needed for the use of all the techniques described. Space has, however, been used prodigally in other ways, and it seems surprising that, among other examples of the historical approach, five pages should be devoted to the derivation of $PV = nRT$, or that a picture of a Fortin barometer which shows few details should occupy nearly a whole page. Most of the large number of illustrations are of the pictorial type found in catalogues, and some demonstrate little beyond the supplier's name; it would have been preferable to leave more room for the text by reducing the number of illustrations of American equipment and including a higher proportion of diagrams of universal application.

The book is well produced, attractive in appearance and gives a readable account of its subject which may be useful to a non-specialist such as myself; but because of its abbreviated treatment, it is unlikely to appeal to the gas analyst.

D. AMBROSE

Parva Naturalia

By Aristotle. A Revised Text with Introduction and Commentary by Sir David Ross. Pp. xi+354. (Oxford: Clarendon Press; London: Oxford University Press, 1955.) 40*s.* net.

THIS book will be valued by all Aristotelian scholars, and by naturalists interested in the early formulation of their science. Present-day psychologists, too, if they consult it, may find a few surprises. For example, the work contains the oldest general formulation of the laws of association. It is well known that some examples of these laws occur in Plato's "Phædo", but the originality of Aristotle's concept is the introduction of contrast. A reference of great historical significance is that to 'Aristotle's experiment' (frequently mentioned by philosophers) in which a marble, if held between the crossed first and second finger of either hand, is 'felt' as two objects. The explanation of the effect is commonly ascribed to our involuntary separation of the contacts as distinct in space.

These are only two of the numerous problems contained in the collection; much else deserves careful thought at the current level of observational technique. It is scarcely necessary to add what a delight the whole volume is—the result of the hand of Sir David Ross upon it.

F. I. G. RAWLINS

POLAR WANDERING: A MARATHON OF ERRORS

By DR. W. H. MUNK*

Department of Geodesy and Geophysics, University of Cambridge

"THE subject of the fixity or mobility of the earth's axis of rotation in that body . . . [has] from time to time attracted the notice of mathematicians and geologists. The latter look anxiously for some grand cause capable of producing such an enormous effect as the glacial period. Impressed by the magnitude of the phenomenon, several geologists have postulated . . . a wide variability in the position of the poles on the earth; and this, again, they have sought to refer back to the upheaval and subsidence of continents." With these words George Darwin introduced his paper[1], "On the Influence of Geological Changes on the Earth's Axis of Rotation"; it occupies forty-two pages in the *Philosophical Transactions*, and its mathematical complexity is in proportion to the length. The paper was published in 1877 when Darwin was thirty-two years old; it is the first of his seventy-two papers on cosmology. Yet this was to remain the only serious study of the dynamics of polar wandering until Gold[2] reopened the problem in a succinct article in *Nature* in 1955. Gold's conclusion differs from Darwin's, but this is only the latest chapter in an extensive, and sometimes heated, controversy that has been going on for seventy years.

Darwin set himself the following problem: at time 0 some continents suddenly commence to rise, others to fall, and the movements continue at a uniform rate thereafter. What would be the position of the axis of rotation if the Earth is (*a*) a rigid solid, (*b*) a viscous fluid? We now consider that the Earth is better described as an elastic solid. Darwin did not consider this case; neither the evidence nor the elastic theory had been developed. We are here concerned only with the orientation of the axis in the body of the Earth; the orientation in space is scarcely altered. It is therefore convenient to refer to the geographical location of the poles of rotation, where the axis pierces the crust.

Darwin's solution (ref. 1, pp. 282–83) consists of oscillatory terms like

$$\exp(-\alpha t)\cos\omega t \qquad (1)$$

plus others that remain after the initial oscillation has become damped out. These have the components (disregarding for the moment a slight separation between axes of figure and rotation):

$$\begin{aligned} x &= \frac{\alpha(\omega^2-\alpha^2)}{\omega^2+\alpha^2}u - \frac{\omega^2}{\omega^2+\alpha^2}ut \\ y &= -\frac{2\omega\alpha^2}{\omega^2+\alpha^2}u + \frac{\omega\alpha}{\omega^2+\alpha^2}ut \end{aligned} \qquad (2)$$

u is a measure of the rate of upheaval, x is the polar displacement toward the centre of upheaval and y at right angles to it.

For undamped oscillations of a rigid Earth, $\alpha = 0$, and

$$x = -ut,\ y = 0 \qquad (3)$$

For reasonable continental upheavals, these solutions must be limited to such times that ut is of the order of a degree of latitude at most, according to Darwin; actually one mile might be a better upper limit. In any event, there can be no appreciable polar wandering on a rigid Earth. The opposite extreme, that of great fluidity, corresponds to large α, and to

$$x = -\alpha u,\ y = -2\omega u \qquad (4)$$

so that x can be made arbitrarily large by taking α arbitrarily large.

Darwin is explicit in the interpretation of his solution: "If the earth be sensibly rigid . . . the geographical path of the axis is very nearly the same as is due merely to the geological deformations of the earth's shape; but if the earth be more or less plastic, . . . the dynamical reactions introduced are such as more or less to modify the geographical path of the axis. In the case of great plasticity these reactions would suffice to alter entirely the character of the path". We have therefore clearly a state of things in which the pole may wander indefinitely from its primitive position. "On this hypothesis, as in successive periods the continents have risen and fallen, the pole may have worked its way, in a devious course, some 10° or 15° away from its geographical position at consolidation, or may have made an excursion of a smaller amount and have returned to near its old position."

Whether or not there had been polar wandering was therefore not a question of dynamics, but depended on whether the Earth was taken as plastic or rigid. The decision was outside the scope of Darwin's analysis, though he favoured the latter alternative: "But Sir William Thomson has shown that the earth is sensibly rigid; and in any case the earth is not a viscous fluid, properly so-called, although it may be slightly plastic".

What was Kelvin's evidence for a rigid Earth? His original argument[3] was by way of reference to Hopkins, "who first adduced the phenomena of precession and nutation to disprove the hypothesis that the solid part of the Earth's mass is merely a thin shell". But this argument is wrong, because precession is caused by the pull of the Sun on the equatorial protuberance regardless of whether it is fluid, elastic or frozen. Kelvin was questioned on this point by Newcomb, and in a presidential address to the British Association[4] Kelvin asked his audience to cross out what he had written on this subject in "Natural Philosophy". (I found the copy in the University Library, Cambridge, to have been defaced accordingly.) Unknown to Kelvin and Newcomb, the error had already been pointed out by General Barnard[5].

---

* Guggenheim Fellow on sabbatical leave from the Scripps Institution of Oceanography, University of California.

Darwin[1] refers to Kelvin's retraction of precession as an argument for rigidity, but adds that Kelvin ". . . adduces, however, a number of cogent arguments on this point". Curiously enough, Kelvin refers here to a paper by George Darwin's great father[6] entitled "Observations on the Parallel Roads of Glen Roy and other parts of Lochaber in Scotland, with an attempt to prove that they are of Marine Origin", in which it is said that the Earth as a whole takes approximately the figure due to gravity and centrifugal forces, because of the fluidity of the interior and the flexibility of the crust. To this statement Kelvin raises the following two objections in his British Association presidential address[4]: (1) "But alas, for this 'attractive sensational idea' . . . that a molten interior to the globe underlies a superficial crust, its surface agitated by tidal waves, . . . the solid crust would yield so freely to the deforming influence of sun and moon that it would simply carry the waters of the ocean up and down with it, and there would be no sensible tidal rise and fall of water relatively to land . . ."; that is, unless the crust consisted of "preternaturally rigid matter", far more rigid than steel; (2) that the "solar semiannual nutation must be largely, and the lunar fortnightly nutation enormously, affected by interior liquidity. . . . This conclusion is absolutely decisive against the geological hypothesis of a thin rigid shell full of liquid". But the argument is not decisive if we ascribe to the mantle a behaviour characteristic of many materials, whereby it responds almost as an elastic solid to disturbances of short period, but flows in response to stress of long duration. I think Darwin's suggestion was well taken[1]: "it seems quite possible that the earth may be sensibly rigid to the tidal deforming influences of the sun and moon, and yet may bring itself back from any considerable departure from a form of equilibrium to approximately that form". Kelvin's foregoing arguments may have had something to do with a letter George Darwin was to receive from his father two years later[7]: "Hurrah for the bowels of the earth and their viscosity and for the moon and for the Heavenly bodies . . . and for my son George (F.R.S. very soon) . . .".

But Kelvin[4] was not yet contented with the two preceding arguments: "But now thrice to slay the slain: suppose the earth this moment to be a thin crust of rock or metal resting on liquid matter; its equilibrium would be unstable! And what of the upheavals and subsidences? They would be strikingly analogous to those of a ship which has been rammed —one portion of crust up and another down, and then all down. Now whatever may be the relative densities of rock, solid and melted, at, or about, the temperature of liquefaction, it is, I think, quite certain that cold solid rock is denser than hot melted rock; and no possible degree of rigidity in the crust could prevent it from breaking to pieces and sinking wholly below the liquid lava".

"And thrice he slew the slain"? The quotation may have been more apt than Lord Kelvin intended. For later during the feast the slain come back to plague the king, and Timotheus cries: "Those are Grecian ghosts, that in battle were slain, . . . behold how they toss their torches on high . . .".

Darwin himself seems to have been well enough convinced by Kelvin's persuasiveness[8]: "A third opinion, contended for by Sir William Thomson [Lord Kelvin], and of which I am myself an adherent, is that the earth is throughout a solid of great rigidity . . .". Thirty-one years later, when his paper was reprinted among his collected works, he wrote[9]: "The conclusions arrived at in my paper are absolutely inconsistent with the sensational speculations as to the causes and effects of the glacial periods which some geologists have permitted themselves to make". Darwin remained on close terms with Kelvin, a friendship that had, in fact, begun with the selection of Kelvin by the Royal Society as referee for the paper here under discussion. An alternative derivation due to Kelvin is included as Appendix *C* to Darwin's paper. Kelvin, according to Darwin, "seemed to find that on these occasions the quickest way of coming to a decision was to talk over the subject with the author himself". Darwin considered that all his work on cosmogony "may be regarded as the scientific outcome of our conversations of the year 1877; but for me at least science in this case takes the second place".

I must refer to one more aspect of the Kelvin–Darwin discussion of polar wandering. Kelvin's arguments for a rigid Earth denied the possibility of polar wandering within the framework of Darwin's analysis. But this should not imply that Kelvin was opposed to shifting the pole over large distances. Far from it. In a passage often quoted by those who favour large polar displacements, Kelvin said[4]: "Considering, then, the great facts of the Himalayas and the Andes, and Africa and the depths of the Atlantic, and America and the depths of the Pacific, and Australia, and considering further the ellipticity of the equatorial section of the sea-level, estimated by Capt. Clarke at about 1/10 of the mean ellipticity of meridional sections of the sea level, we need no brush from the comet's tail (a wholly chimærical cause which can never have been put forward seriously except in ignorance of elementary dynamical principles) to account for a change in the earth's axis; and we may not merely admit, but assert as highly probable, that the axis of maximum moment of inertia and the instantaneous axis of rotation, always very near one another, may have been in ancient times very far from their present geographical position, and may have gradually shifted through 10, 20, 30, 40, or more degrees without at any time any perceptible sudden disturbance of either land or water". These views were reprinted in Kelvin's "Collected Works"[10] in substantially their original form.

So far as I can see, Kelvin reasoned as follows: the surface of the Earth is divided into quadrants; in the northern hemisphere a rise is centred at 0° longitude (say) and a fall at 180°, in the southern hemisphere a fall at 0° and a rise at 180°. For a maximum crustal displacement of 10 cm. the pole of a rigid earth is shifted by 0·1″. Then by what Kelvin calls a "simple effort of geological calculus" he finds that for a corresponding surface displacement by 10 km. the pole is moved through nearly 40° latitude. Kelvin had assumed the Earth to be sufficiently rigid to sustain a distortion commensurate with the dimensions of the equatorial bulge. Of course, this must lead to appreciable polar wandering, but it would seem to be the hard way of doing it.

We return to Darwin's solution (equation 2). It may have been noticed that the first terms in x and y have the dimensions length/(time)^2 instead of length. This is the result of a simple algebraic error made earlier in the derivation. The mistake was discovered by Lambert[11]; the corrected equations are given by Jeffreys[12]:

$$x = \frac{\alpha(\omega^2 - \alpha^2)}{(\omega^2 + \alpha^2)^2} u - \frac{\omega^2}{\omega^2 + \alpha^2} ut$$
$$y = -\frac{2\omega\alpha^2}{(\omega^2 + \alpha^2)^2} u + \frac{\omega\alpha}{\omega^2 + \alpha^2} ut \qquad (5)$$

All terms now tend to zero as α becomes infinite. There can be no polar wandering no matter how fluid the Earth is. This conclusion contradicts the previous result (equation 4).

For simplicity we now restrict ourselves to the case $\alpha \ll \omega$. Equation (5) can then be written

$$x = (\alpha/\omega)(u/\omega) - ut, \qquad y = 0 \qquad (6)$$

The approximation $\alpha \ll \omega$ is amply justified by the observation that the damping of the free nutation requires many periods. Subject to the same assumptions and restrictions, I find, in an independent derivation,

$$x = (\alpha/\omega)(u/\omega) - ut - \tfrac{1}{2}\alpha ut^2, \qquad y = 0 \qquad (7)$$

The solutions differ by the term in t^2, and this term yields substantial polar wandering as a consequence of surprisingly small continental upheavals. Equation (7) has the pole move at a constant *acceleration* in response to a constant *velocity* of upheaval. Had Darwin chosen the simpler (and sufficient) example of a sudden vertical displacement, the result would have been a polar wandering at constant velocity. My solution agrees on all essential points with Gold's conclusions arrived at by non-analytical reasoning.

To point out the difference between Darwin's (corrected) solution, and Gold's conclusion, we must return to the basic considerations that underlie Gold's hypothesis. The pole of figure is a position where the axis of figure (about which the moment of inertia is a maximum) pierces the crust. For a rigid Earth the displacement of the pole of figure by $x = -ut$, $y = 0$ is entirely determined by the prescribed upheaval. The pole of rotation circles the pole of figure once every ten months. In the case of a yielding Earth, there is an additional displacement of matter as the geoidal protuberance attempts to adjust to the disturbed position of the rotation axis. The total displacement of the pole of figure is then the sum of displacement of the geoidal pole and that determined by the prescribed upheaval. From dynamic considerations one finds that the velocity of the rotation pole is proportional to its separation from the pole of figure, and from elastic (or plastic) considerations that the velocity of the geoidal pole is proportional to its separation from the pole of rotation. It is, according to Gold[2], "as with the ass and the carrot hanging from a stick held by the rider". The geoidal pole pursues the rotation pole, the rotation pole pursues the pole of figure, which in turn is continuously being displaced by the geoidal pole.

Darwin's reasoning is implicit in his equations 1–4 (ref. 1, p. 282). The sum of the four equations is equivalent to the above-mentioned dynamic considerations. But equations (3) and (4) state that the geoidal pole moves at a rate proportional, not to its separation from the rotation pole, but to the separation of the rotation pole from the pole of figure. I cannot think of any reason for this type of behaviour; it would be consistent, for example, with a stationary solution for a liquid, rotating Earth where the poles of figure and rotation are united, with the geoidal pole being elsewhere.

Darwin obtained his four equations from what he calls geometrical, rather than dynamical, considerations. The important thing is that they do not follow from a deductive argument, and he seems to have gone astray in the formulation of the last two equations. When these are modified in the above sense, then equations (7) follow once more. On the basis of the present development of the theory of elasticity, which was not available to Darwin, it is possible to proceed from fundamental principles to a solution without any break in the deductive argument, and this is, in fact, the method whereby equation (7) was derived.

We are left with three solutions: Darwin's original solution (2) made polar wandering possible; the corrected solution (5) made it impossible; and the modified solution (7) makes it easy. That the final outcome is not in contradiction to the original conclusion is a result of having made an even number of errors. But there is an important difference; equation (2) requires a large value of α for polar wandering, (7) does not, and is in fact based on the assumption that $\alpha \ll \omega$.

In the light of these developments, the many papers that have centred on Darwin's work assume grotesque proportions. Long before Darwin wrote, Comte de Buffon had founded the 'Catastrophic School' of polar wandering to account for palæoclimatic evidence. Darwin clearly hoped his paper would put certain restraints on contemporary arguments for polar wandering by Lubbock, Delabeck, Evans and others. In fact, it was followed by a renewed wave of enthusiasm for large polar displacements, which reached its peak in "Die Pendulations Theorie" of Reibisch and Simroth. Darwin's student, the astronomer Brown, countered these claims with apparent exasperation[13]: "[Darwin's] conclusion, now well known to astronomers, but frequently forgotten by geologists even at the present time is against any extensive wanderings of the pole during geological times". In 1914, Barrell[14] reviewed "The Status of Hypotheses of Polar Wanderings" as follows: "Geologists and biologists may array facts which suggest such hypotheses, but the testing of their possibility is really a problem of mathematics. . . . Notwithstanding this, a number of hypotheses concerning polar migration have been ingeniously elaborated and widely promulgated without their authors submitting them to these final tests. . . . Others, of more logical mind, recognizing the need of mathematical justification, have thought to find a qualified support in the work of Kelvin and G. H. Darwin. . . . The work of Darwin, instead of permitting hypotheses of polar wanderings, offers the most convincing proof which is available that migrations of the axis of the earth sufficiently extensive to be of geological importance have not occurred [*sic*]. . . . His [Darwin's] papers seem to have checked further speculation upon this subject in England, but, apparently unaware of its strictures, a number of continental geologists and biologists have carried forward these ideas of polar wandering to the present day. . . . Does not the history of the subject show the dangers of over-specialization within one division of science with the consequent putting forth of hypotheses regardless of the verdict of related Sciences?".

In this controversy between physicists and geologists, the physicists, it would seem, have come out second best. They gave decisive reasons why polar wandering could not be true when it was weakly supported by palæoclimatic evidence; and now that rather convincing palæomagnetic evidence has been discovered[15], they find equally decisive reasons why it could not be otherwise.

BOOLE'S "THE LAWS OF THOUGHT"

By F. I. G. RAWLINS

THE Royal Irish Academy has done well to collect and issue a series of papers* commemorating the appearance of "The Laws of Thought" by George Boole in 1854. The occasion was a centenary celebration in Dublin, and here is a permanent record, bearing witness both to the unique character of the book itself, and in parallel, so to say, to the remarkable personality of its author. If ever a publication reflected the innermost being of its originator, this volume assuredly did. Its production, moreover, stands as a monument to the foresight of the electors to the chair of mathematics at Queen's College, Cork, who appointed a candidate without a university degree, and devoid of formal academic training. It is rather as if a similar choice had been made of Ramanujan many decades later, before he went to Trinity College, Cambridge, to carry all before him.

Most appropriately, Sir Geoffrey Taylor opens the series with a graphic account of his grandfather's life. And what a life it must have been; serene, highly disciplined, creative at every stage, both in research and in the task of imparting knowledge. For even when Boole was school-mastering in Lincoln as little more than a youth he was experiencing the joy of discovery, as he read and mastered the works of the French mathematicians. Alongside all this, he taught himself several languages, as if to foreshadow the development of semantics as the century wore on.

Boole had a great appreciation of the place of tranquillity in the intellectual life. We read of him taking a "solitude à deux" with a friend to the Alkborough Hills near his peaceful Trent, and sitting down alone under a bush in the evening. From this excursion arose the precursor of his analytical studies which he later improved and expanded in "The Laws of Thought". At times his inclination seems to have been towards algebraic methods rather than in the direction of geometry, believing the former to be the more powerful instrument. But as we shall see later, this was no lopsided view. His grasp was so sure that, analyst as he sometimes was, history will credit him as a great architect in synthesis.

How exactly did this come about? The answer is to be found in Boole's attitude to Nature. He believed profoundly that there was such a thing as unity *of* Nature, and unity *in* Nature. In these two concepts, which went far to mould the entire pattern of his life, he approximated to Leonardo da Vinci, with his deep veneration for natural law. The method of Boole is based upon this one-ness, and enmeshed in it are the seeds from which has flowered much of the propositional calculus as we now have it, and a great part of the powerful machinery of modern logistics. It must not be too readily deduced from this, however, that the meta-sciences of to-day spring directly from "The Laws of Thought"; what has in fact happened is that out of traditional logic has appeared a means whereby it has become possible to raise such a majestic structure that the elements of Aristotelian thought still embedded in it comprise but a minute fraction of the whole. It is an example on the grand scale of the eternal verity that nothing can be quickened except it die. The sower of that particular harvest was George Boole.

We can now, with this in mind, attempt some appraisal of the method of this remarkable man, and we shall not get far without observing certain features in common with the outlook of Alfred North Whitehead. It is probably no accident that much the same logical pressure acted upon the mind of Boole as it did much later upon the authors of "Principia Mathematica". The essence of his method is to begin with things rather than words; with objects before concepts. Then follows the paramount need to train the mind by rigorous exercise, including the working out of numerous examples. One may compare this with Whitehead's belief in the use of the simplest possible apparatus, to squeeze the last drop of juice out of any problem amenable to experiment. Just as Leonardo da Vinci took infinite pains (somewhat against the grain) to study the works of Archimedes, so we find Boole ever ready to relate his abstractions to things as we find them. His insistence upon the acquisition of a beautiful and legible handwriting gives us a clue to the importance which he attached to means as well as ends. He was human enough to seek relief from pure speculation by resorting sometimes to "mechanical employments", while conversation he regarded as an entertainment, not as an occasion for strife.

Strong traditionalist as he was—as we have already seen—Boole's concept of the construction of a physical science has a present-day familiar look. In "The Laws of Thought" he finds four stages: namely, observation, presumption (that a law exists), experimental tests, and the investigation of causes. In addition, his emphasis upon increasing probability towards the limit of certainty as confirmatory data increased shows how sure an insight he had of a methodology well ahead of his time. This is noteworthy when one recollects that Boole was working at a period when laboratory techniques were very limited and—supposedly—his own contacts with them of the most slender kind.

---

* Proceedings of the Royal Irish Academy. Vol. 57, Section A, No. 6: Celebration of the Centenary of "The Laws of Thought" by George Boole Pp. 63–130. (Dublin: Hodges, Figgis and Co., Ltd., 1955.) 6s.

In passing from here to some evaluation of Boole's place in logic, the elementary fact of history—that the subject had been static "at the same level of very elementary deduction" for some two thousand years—throws into relief the achievement of infusing new life in the form of a conscious mathematical logic into something which had eluded Leibniz and Lambert many years before. All this was propounded in the "Mathematical Analysis of Logic" (1847), and elaborated in "The Laws of Thought". In essence, Boole set about calculating as an algebraist would, afterwards eliminating such terms as were incapable of a logical interpretation. According to him, however, the equality $xx = x$ is unique. In ordinary algebra this is only true for $x = 1$ and $x = 0$, whereas in logic it holds for all values of x. From this he goes on to assume that the laws of his algebra only exceed those of ordinary algebra in this one particular. A number of criticisms have been made of Boole's system both in regard to mathematical rigour, and touching the æsthetic point that in some degree it lacked elegance. No doubt, as one commentator observes, there were some tares among the wheat, and they grew together until the harvest. Time has exterminated the chaff.

A trio of papers in the collection under notice brings the story of Boole's genius up to date by a discussion of the relation of his methods to contemporary many-valued logics, his concept of a function, and the influence of institutionalism upon the classical algebra of logic. Finally, comes a contribution dealing with an engineering application of Boolean algebra, which turns out to be an extremely powerful calculus for the determination of electrical circuits comprising two-state switches, that is, those that can be only 'on' or 'off'. In the case of complex problems in telephony, it can make possible major advances in communication theory, by simplifying equations otherwise almost unmanageable in practice.

In brief, the life and work of George Boole as reflected in "The Laws of Thought" are the perfect illustration of the truth of Whitehead's dictum: "You may not divide the seamless coat of learning".

THE COLE MUSEUM OF ZOOLOGY

UNIVERSITY OF READING

It is fifty years since the appointment of Prof. F. J. Cole to the Department of Zoology in University College, Reading (now the University of Reading). One of the factors that contributed to Reading's rise to the status of a university was the fact that several men and women of high quality identified their careers with her, and Prof. Cole was one of them. Soon after his arrival he started to build up a museum of zoology, and when he retired in 1939 he had the satisfaction of seeing his Department endowed with one of the finest teaching museums in Great Britain. An appreciative Council decreed that it should remain as a permanent memorial to him with the name of 'The Cole Museum of Zoology'.

Small though the Department was, it was from the beginning the special duty of one of the members of the staff to care for the growth and maintenance of the Museum. From 1912 until 1919 this was Miss (now Dr.) Nellie B. Eales, and from 1921 to the present time Mr. W. E. Stoneman has held the curatorship.

The exhibits now number more than three thousand, and each is described in the manuscript catalogue, where references to original publications are found and drawings help to interpret intricate parts. This is the source-book for the Museum's history, and it is appropriate to celebrate its jubilee by recalling some of the highlights.

Prof. Cole appealed to zoological friends all over the world, asking for particular animals in accordance with a careful plan. Prof. Ijima of the University of Tokyo, a world authority on the Porifera, collected and prepared in his own laboratory the magnificent series of Hexactinellid sponges. He, moreover, went to sea six times before he succeeded in dredging from the depths of the ocean the fine sea-lily (*Metacrinus*) which now adorns the Echinoderm case. Skeletons of a record python and an orang were contributed by Dr. Hanitsch, formerly director of the Raffles Museum, Singapore. Mr. Alfred Palmer, by a generous donation, made possible the purchase of a fine gorilla skeleton to complete the Huxleyan series—gibbon, orang, chimpanzee, gorilla, man. Captain C. R. S. Pitman, when game-ranger of Uganda, sent such animals as the tree pangolin and the lung-fish, *Protopterus*. The Australian Government presented specimens of the echidna and the platypus, from which dissections, skeletons and stuffed skins were prepared. Dr. Johannes Schmidt provided a set of stages of the *Leptocephalus* larva (eel) up to its metamorphosis. An officer of an Antarctic whaling ship prepared a group of specimens to illustrate the auditory organ of the whale, and a beautiful and perfect exhibit is the result. From the *Discovery* collections also many gifts were received. Old students going abroad were briefed to obtain specimens, and to them the Museum owes its Java pangolin, West African manatee, bats and monkeys, Central African hyrax, giant millipedes and scorpions and Mauritian lemurs and tenrecs.

The fullest use was made of all this valuable material. A single *Cryptobranchus* from Japan yielded a complete skeleton and preparations of the heart, arterial arches, gut, renal and reproductive organs, as well as a stuffed skin.

Dissections form a major part of the collection, and they include numerous injections of blood vessels, lymphatics and air-sacs. A former student, Dr. D. H. Tompsett, prosector at the Museum of the Royal College of Surgeons, prepared an exquisite Marco resin cast of the pulmonary vessels and bronchi of a sheep, and another of the cavities of the human brain, both of which were presented by the College.

Transparencies, in which the bones and cartilages are stained to show the skeletal parts *in situ*, have been made by Mr. Stoneman. There are wax models of invertebrate larvæ, mostly prepared by Mr. W. Rogers, laboratory steward, from the fine collection of microscope slides of marine larvæ made at Port Erin by the late Mr. H. C. Chadwick and purchased from him. Gastropod development is illustrated by copies of Dr. Doris Crofts's models of *Haliotis* larvæ.

Among the Museum's treasures are numerous delicate preparations of medusæ, corals and sea-pens with polyps expanded, from Naples Marine Biological Laboratory, preserved especially for the Museum by Cavaliere Salvatore Lo Bianco. They were probably the last specimens preserved by that greatest of preparators of marine material.

At one time the Museum of the Royal College of Surgeons, with its long history from Hunter to R. H. Burne, was Reading's nearest parallel and exemplar; but this was destroyed by bombs in the Second World War. The Cole Museum was built up probably in the last years when such things were possible. Thirty years ago it was adequately housed in the room which it still occupies, and now congests. It is greatly to be hoped that on the new University site a worthy building will be planned for the Cole Museum and that provision will be made to maintain what is a unique asset, not only for the University of Reading, but also for the entire country. Since this project may be many years ahead, we look to the University authorities to preserve the Museum intact, perhaps, if necessary, in a temporary building big enough for the whole collection to be adequately displayed and used.

OBITUARIES

Prof. Kurt G. Stern

Kurt G. Stern died on February 3 of a heart attack in St. Mary's Hospital, London, in his fifty-first year. Born in Tilsit, he attended elementary and grammar school there and moved to Berlin for his higher education, where he received his Ph.D. in 1930 at the University. In the following year he won a Rockefeller fellowship, worked for one year at the Rockefeller Institute in New York, and for two more years at the Courtauld Biochemical Institute in London. When he was to return to Germany in 1935, the Nazis had taken over and Dr. Stern decided to accept a research fellowship at Yale University in New Haven, where he became a research associate in 1938 and joined the Overly Research Foundation in 1942. Two years later he was offered a post as research associate and adjunct professor at the Polytechnic Institute of Brooklyn, in which position he remained until his death.

Stern's influence on the development of biochemistry rested on the combination of several distinguished qualities: he was an excellent lecturer and an inspiring teacher; he was a meticulous experimentalist with an innate urge for precision and accuracy, and on top of it all he had a never-failing flair for selecting problems of general importance and far-reaching significance. He was strongly attracted by questions connected with the fundamental aspects of life, and hence biochemistry, biology and physiology were the sources from which he selected his problems; but with equal firmness he adhered to the exact quantitative and reproducible methods of physical chemistry and physics. As a consequence, for many years, his activities developed in the borderland between different sciences, taking problems from one and solving them with methods taken from another. In this difficult, self-assigned task, Stern succeeded not only in introducing precise methods in fields where they were unknown, but also in inventing and constructing many new instruments for the purification and characterization of biological objects, particularly enzymes, virus, proteins and nucleic acids.

While he worked and taught at the Polytechnic Institute of Brooklyn, he also acted as chemical consultant at the Montefiore Hospital in the Bronx; and it was a fitting expression of his constant tendency to bridge gaps between different sciences that each day he moved in the morning through the corridors of a busy hospital at one end of New York's metropolitan area, and in the afternoon lectured and supervized fundamental research in the laboratories of the Polytechnic Institute of Brooklyn at the other end. This type of work he liked; thus he contributed innumerable important results, and in both fields he was highly esteemed and liked by his colleagues and collaborators.

Dr. Stern's activities and efforts won him many recognitions and honours. He served as chairman of the Protein and Nucleic Acid Week of the Gordon Research Conferences; he was the secretary of the Planning Committee of the Chaim Weizmann Institute in Rehovoth; he was president of the American Society of European Chemists and Pharmacists and he served on many occasions as chairman of special symposia arranged by the American Chemical Society, the New York Academy of Sciences and in other scientific and technical organizations. He was awarded in 1953 the Pasteur Medal of the French Society of Chemistry and Biology.

His great scientific achievements and professional success were equalled by his warm, friendly and helpful personality. Everybody who came into contact with Dr. Stern was impressed by his high ideals, his devotion to the cause of science and his unfailingly deep interest in social and human relationships.

H. Mark

Mr. Horatio Ballantyne

Horatio Ballantyne, who died on January 25 at his home at Tadworth, Surrey, in his eighty-fifth year, was a consulting chemist and expert witness in patent cases whose theoretical knowledge was firmly buttressed by wide practical experience. His transfer from this field of activity to the Board of Lever Bros. in 1928, while at the height of his powers, though doubtless of benefit to commerce and industry generally and to that great Company in particular, left a gap in the ranks of scientific witnesses, and when, a few years later, his boyhood friend, Sir Dugald Clerk, the patent agent and expert on internal combustion engines and gaseous fuels, passed away, the fundamental contribution which they had made to the administration of the patent law was demonstrably evident. In engineering matters, Sir James Swinburne, the late Mr. H. A. Gill and Horatio's younger brother, the late Mr. W. H. Ballantyne, provided an adequate complement; but their gallant efforts to assist in cases arising in other scientific fields only made it more manifest that the day of the comprehensive scientific expert witness had come to an end.

The Reports of Patent Cases bears witness to Ballantyne's amazing versatility. From his début in the famous Welsbach gas mantle litigation, he assumed the burden of scientific exposition in patent cases for more than thirty years, dealing with topics as diverse as gramophones, electric lamps and filaments, steel ball grinders, coal-cutting machines, typewriters, confectionery, the drying of milk and a host of others. The first encomium he received was in his first case and came from Mr. Justice Wills, who said in his judgment: "I wish to add that Mr. Ballantyne has given me reason to rely on him. He is one of the most truthful and fairest minded men I have seen in the witness box". The last to my knowledge appears in an appreciation by Sir Kenneth Swan, a distinguished leader of the Patent Bar and himself a son of a great inventor. He wrote: "His evidence, invariably characterized by scrupulous candour and fairness, was not only backed by profound technical knowledge, but was always based on a careful and crucial experiment; moreover it was given with that degree of precision and tenacity that rendered it proof against the most penetrating cross-examination. In short, he was a pattern of what an expert witness should be". Both, it will be noted, remarked Ballantyne's candour and fair-mindedness, two attributes which the experienced judge will thankfully recognize, and without which the most profound scientific knowledge will fail to impress. The value of an expert witness resides in the weight attached to the expression of his opinions. He must, of course, be technically competent and preferably free from addiction to technical jargon. But in the ultimate result, his assistance in the administration of justice will depend not only upon his perception and expression of truth, but upon the manner in which he completes and isolates it. In this Ballantyne was pre-eminent, and that explains why it was that, in cases involving scientific questions with which he was only generally familiar, his assistance was often more valuable than the evidence of more specialized experts.

Horatio Ballantyne was born at Glasgow in 1871. His father, Thomas Ballantyne, who was a pioneer of unitarianism in Glasgow, was married twice, and had thirteen children, Horatio being the eldest son and first child of the second marriage. His father died when Ballantyne was fifteen years old.

At fourteen he left school to begin work in the laboratory of Robert Tatlock, city analyst for Glasgow. It had been planned that he should go to the University, having gained a bursary that would have enabled him to do so, but the young Ballantyne resigned the bursary and went to Tatlock's, starting at a wage of 2*s*. per week.

It was a very busy commercial laboratory, with a large Students' Department attached, and gave a really extensive training in industrial chemical analysis. After some time Ballantyne became chief assistant, and Tatlock and his partner Thompson invited him to become, in 1898, a member of the firm when Dr. J. B. Readman was due to retire; but brighter prospects came his way.

During the years with Tatlock, he had opportunities for carrying on research, especially into the little-understood chemistry of the oils and fats. Some accounts of these investigations were published in the *Journal of the Society of Chemical Industry*. In the evenings he attended classes in chemistry, mineralogy, German, etc. He took first place in Great Britain in the 'South Kensington' examination in honours chemistry, and the first place also (with medal) in the Society of Arts examination in German.

In March 1896 occurred an event which determined the course of his professional life. A few years before that date, Tatlock had received from Norway some samples of minerals which were to be tested for what was then known as the "rare earths", especially yttrium, cerium, lanthanum and thorium oxides. The invention of the incandescent gas mantle by Auer von Welsbach had given a special value to such earths, the chemistry of which was quite unknown to chemists in general. Tatlock had passed on to Ballantyne the problem of working out methods of analysis, etc., and he became in a small way a specialist in this recondite subject.

The Welsbach Incandescent Gas Light Co. of London acquired the rights to the British Welsbach patents, and by the year 1895 had become so successful that many infringing manufacturers appeared. An action for infringement of patent was brought against one of them. Towards the end of October 1895 a specimen of the infringing article was sent to Tatlock for analysis, and as it was said to be made of the rare earths he handed over the problem to Ballantyne. In March 1896 Ballantyne was asked unexpectedly to proceed immediately to London to be present at the trial of the action. The case began before Mr. Justice Wills. Fortunately for Ballantyne, it turned out to be the most important case of the time. The principal leaders of the Patent Bar were engaged in it, as were the leading expert witnesses (Sir Henry Roscoe, Prof. (Sir) James Dewar, Dr. Otto Hehner, (Sir) James Swinburne, Dr. Dupre, (Sir) Dugald Clerk, John Murrey, Prof. Vivian B. Lewes, Prof. Lambert, etc.). Leading counsel for the patentee was J. Fletcher Moulton (afterwards Lord Moulton), at that time the most distinguished counsel at the Patent Bar. The trial of the action was very protracted. Most of the work on the controversial matters fell upon Ballantyne's shoulders and he worked feverishly, night and day. Three times he was called to the witness-box. Such was the event which began Ballantyne's career as an expert witness and led him to specialize in patents and cognate matters.

Ballantyne was elected vice-president of the Institute of Chemistry in 1918, and again for the years 1920–22. He served on a number of Board of Trade departmental committees dealing with patent law and practice and with inventions made in government service. He married in 1899 Miss K. Russell, who survives him with the three daughters of the marriage.

G. H. LLOYD-JACOB

Mr. D. B. Waters

DAVID BOWE WATERS, whose death occurred on February 7 at Glasgow at the age of forty-three, was a civil engineer and was responsible during the Second World War for much of the detailed technical development at the Road Research Laboratory (Department of Scientific and Industrial Research) of the devices known as 'plastic armour' and 'plastic protective plating': these materials were used on most of the Allied merchant ships for the protection of vital parts from aircraft cannon fire. 'Plastic armour' consisted of a tightly packed mass of stone particles held together by a bituminous mortar and backed by a steel plate; 'plastic protective plating' was an even denser material with a higher stone content compacted by vibration and encased in thin sheet steel. In essence, these devices provided a protective layer, the resistance of which to penetration was highly irregular, thus causing projectiles to yaw away from a straight path.

Mr. Waters joined the Bituminous Section of the Road Research Laboratory in 1936: at the time of his death he was in charge of the Laboratory's Scottish branch at East Kilbride. His colleagues will long remember his originality of mind, enlivened always by gaiety and wit.

Dr. Ernst Wanner

Dr. Ernst Wanner was born in Zurich on July 22, 1900. In 1925, he was awarded the degree of doctor of mathematics at Zurich for work on groups of linear transformations, and in 1928 was appointed to the Swiss Meteorological Service, where he remained until his death from a heart attack on November 4, 1955. He worked on magnetic variations at Regensberg and on seismology at Zurich. Latterly he was vice-director of the Swiss Meteorological Service and responsible for personnel. That he was successful in both these fields is a tribute to him both as a scientist and as a man. He was basically good-natured, modest and very straightforward.

With A. Kreis, Wanner constructed a 1,000-kgm. vertical seismograph, which assisted him in obtaining data for the study of Swiss earthquakes and their impact on Alpine structure. He also studied Swiss earthquakes historically, compiling a catalogue of shocks between the dates 1856 and 1879. With all this material he was able to work out the correlation between earthquake epicentres in Switzerland and Swiss Tertiary volcanics and thermal springs. He used a method due to G. Polya and F. Eggenberger on the coupling of earthquake aftershocks. Finally, with P. L. Mercanton, Wanner studied the magnetic anomaly in Jorat, near Lausanne.

Wanner was president of the Swiss Committee of the International Union of Geodesy and Geophysics, vice-president of the International Association of Seismology and the Physics of the Earth's Interior, and the Swiss representative on the European Seismological Commission. He was unmarried.

Ernest Tillotson

NEW FELLOWS OF THE ROYAL SOCIETY

At the meeting of the Royal Society on March 15, the following were elected to fellowship:

Dr. N. P. Allen, superintendent, Metallurgy Division, National Physical Laboratory, Teddington, Middlesex, distinguished for his work on alloy steels, their transformations, and their engineering properties

Prof. J. F. Baker, professor of mechanical sciences, University of Cambridge, distinguished both for his experimental and theoretical investigations of steel structures and for services to education in engineering.

Prof. R. M. Barrer, professor of chemistry, Imperial College of Science and Technology, London, distinguished for his work on the mechanism of adsorption and diffusion of gases in solids and the problem of molecular sieves in zeolite minerals.

Dr. R. Brown, head of the Agricultural Research Council Unit of Plant Cell Physiology, Oxford, distinguished for his work on germination of parasitic seeds and isolation of germination hormones, also for studies of factors involved in cell division and development.

Prof. J. A. V. Butler, professor of physical chemistry, University of London, distinguished for his work on thermodynamics, and the application of physical techniques for the solution of problems of molecular structure of deoxyribonucleic acids.

Dr. D. Gabor, Mullard reader in electronics, Imperial College of Science and Technology, London, distinguished for his work on transient electric phenomena, electron microscopy, the theory of communication and the electric arc plasma.

Dr. H. Gruneberg, reader in genetics, University of London, distinguished for his investigations into the expression of genes during development in mammals.

Dr. C. S. Hallpike, director, Otological Research Unit of the Medical Research Council, London, distinguished for his investigations of the physiology and pathology of the internal ear and the mechanisms of hearing and equilibration.

Prof. J. E. Harris, professor of zoology, University of Bristol, distinguished for his researches in several branches of experimental zoology.

W. K. Hayman, reader in analysis, University of Exeter, distinguished for his contributions to the theory of functions of a complex variable.

Prof. N. Kemmer, Tait professor of natural philosophy, University of Edinburgh, distinguished for his pioneering work on the fundamental particles of physics, particularly on the meson and its role in determining forces within the atomic nucleus.

Dr. N. Kurti, lecturer and demonstrator in physics, University of Oxford, and Senior Research Fellow, Brasenose College, distinguished for his work on phenomena at very low temperatures, particularly in paramagnetism and nuclear alignment.

Dr. R. G. MacFarlane, Radcliffe lecturer in hæmatology, University of Oxford, distinguished for his studies on blood coagulation and their application for the treatment of hæmophilia.

Dr. R. Markham, principal scientific officer, Plant Virus Research Unit (Agricultural Research Council), Cambridge, distinguished for his studies on plant viruses and for his contributions to knowledge of nucleic acids.

Dr. J. W. Mitchell, reader in physics, University of Bristol, distinguished for his work on the action of light on crystals, particularly in photographic emulsions, and on the nature of the photographic latent image.

Prof. W. D. M. Paton, professor of pharmacology, Royal College of Surgeons, London, distinguished for his work on the relation between chemical structure and pharmacological action, and for the discovery of several important new drugs.

Dr. A. B. Pippard, lecturer in physics, University of Cambridge, distinguished for his work on the electrical properties of metals at radio-frequencies, and for his studies of the superconducting state.

Dr. Helen K. Porter, principal scientific officer, Research Institute of Plant Physiology, Imperial College of Science and Technology, London, distinguished for her work on fructosans of leaves, on carbohydrate metabolism of fruits and cereals and for enzymological studies on polysaccharide syntheses in plants.

Dr. G. Salt, lecturer in zoology, University of Cambridge, distinguished for his experimental and ecological researches on insects, especially on parasitic Hymenoptera.

Prof. C. W. Shoppee, professor of chemistry, University College, Swansea, distinguished for his contributions to organic chemistry with special reference to the elucidation of problems of stereochemical relationships in the steroid field.

Prof. F. W. Shotton, professor of geology, University of Birmingham, distinguished for his contributions in stratigraphy and particularly for his work on the Pleistocene deposits of the Midlands.

Dr. E. I. White, keeper of geology, British Museum (Natural History), London, distinguished for his research on the earliest vertebrates and fossil fishes, particularly those from the Old Red Sandstone.

Dr. M. V. Wilkes, director, University Mathematical Laboratory, Cambridge, distinguished for his contribution to the design and construction of automatic calculating machines, and their application to the solution of a wide variety of scientific problems.

Dr. D. H. Wilkinson, lecturer in physics, University of Cambridge, distinguished for his researches in nuclear physics, especially his investigation of the properties of the energy levels of light nuclei.

Prof. A. Wormall, professor of chemistry and biochemistry, St. Bartholomew's Hospital Medical College, London, distinguished for his researches in biochemistry and for his 'pioneer work in the development of the use of isotopes in immunochemistry.

NEWS and VIEWS

Physical Metallurgy at the Imperial College, London: Mr. J. G. Ball

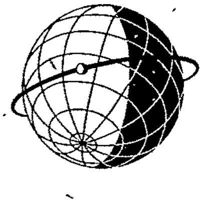
Mr. J. G. Ball, of the Atomic Energy Research Establishment, has been appointed to the chair of physical metallurgy in the Imperial College of Science and Technology, University of London. After leaving the University of Birmingham, Mr. Ball joined the Welding Research Council in 1941. When this became the British Welding Research Association in 1945, he was appointed senior metallurgist with responsibility for establishing and directing the metallurgical laboratories; there he initiated a programme of basic work on light alloy and structural steel welding. Mr. Ball led a strong team on steel welding which has made fundamental contributions to the understanding of welding behaviour and the development of new alloy steels of good weldability. He was particularly associated with developments in the fabrication of Bailey bridges and is a member of a Ministry of Supply Committee on this subject. He joined the Atomic Energy Research Establishment, Harwell, in 1949, to take charge of investigations on the metallurgy of plutonium, and he pioneered the special techniques for handling plutonium and for micro-scale investigations. He was jointly responsible with Dr. R. Hurst for the design of the new plutonium laboratory at Harwell, which is based on new principles and incorporates novel techniques. The plutonium core for the fast reactor Zephyr was fabricated under his direction. For the past three years he has been head of the Reactor Metallurgy Group in the Metallurgy Division, and has given much attention to the problems of irradiation behaviour of fissile materials and the design and behaviour of fuel elements. Mr. Ball is a member of the Council of the Institution of Metallurgists. With Mr. Ball's appointment, it is intended that the development of the research and postgraduate activities in metallurgy at the Imperial College will have a bias towards the metallurgy of nuclear energy.

Chemistry at Rothamsted Experimental Station: Dr. G. W. Cooke

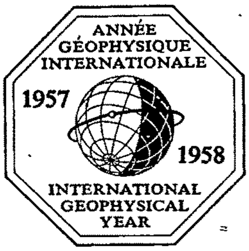
Dr. G. W. Cooke has been appointed head of the Chemistry Department of Rothamsted Experimental Station, in succession to Dr. R. K. Schofield, who has gone to the Department of Agriculture, University of Oxford (*Nature*, 176, 910; 1955). Dr. Cooke was educated at Loughborough Grammar School and (the then) University College, Nottingham, graduating with first-class honours in chemistry in 1937. After postgraduate research in biochemistry with the late Prof. J. M. Gulland, he joined the Chemistry Department at Rothamsted as a Ministry of Agriculture research scholar. In 1940 Dr. Cooke obtained his Ph.D. for a thesis on soil phosphate chemistry. During the Second World War he was concerned with testing new phosphate fertilizers which were made as alternatives to superphosphate. Afterwards he turned his attention to improving the efficiency of fertilizers by developing special methods of application. This work, which proved the value of fertilizer placement practices for certain crops, is already being applied by farmers His experience in fertilizers has led to Dr. Cooke being invited to carry out short-term work for both the Food and Agriculture Organization and the Organization for European Economic Co-operation. He has been honorary secretary of the Agriculture Group of the Society of Chemical Industry, of which he is at present vice-chairman. He has also served on the Council of the Fertilizer Society.

Symbol for the International Geophysical Year

It has been decided to use the following symbols in connexion with the International Geophysical Year:



(1)



(2)

Symbol 1 is a representation of the Earth with meridians and circles of latitude, showing the south pole, to signify the special antarctic features of the International Geophysical Year; part of the Earth is shown in darkness, implying the influence of the Sun; a satellite orbit is shown encircling the Earth at an inclination to the equator, with the satellite, of course exaggerated in size, shown partly sunlit. Symbol 1 is to be used without change on publications issued by the Comité Spécial de l'Année Géophysique Internationale (CSAGI) and other International Geophysical Year publications under rules issued by the General Secretary of the Comité Spécial. This symbol does not include an inscription because the relevant information will normally be printed on the title page and cover of each publication. Symbol 2 is to be used on instruments, equipment or uniforms of personnel associated with the International Geophysical Year national committees, where the French or English language is appropriate; other national committees will substitute a translation of the inscription in the relevant language. If commemorative postage stamps are to be issued by any nation, the inscription may be used with the central symbol but otherwise disposed and with a border other than the octagonal one.

Man-power in the Royal Air Force

In submitting the Air Estimates to the House of Commons on March 5, the Secretary of State for Air, Mr. Nigel Birch, referred at some length to the problem of saving man-power. Apart from limited inquiries into specific aspects of the subject, in which the Royal Air Force has had the assistance of business men, trade union officials and others, imaginative and effective work is going on all the time in the Royal Air Force itself, which has, he claimed, pioneered the application of scientific methods to the man-power question. This work has aimed not only at saving man-power but also at adjusting establishments in a highly technical and rapidly changing Service; further, the Air Ministry Man-power Research Unit has been in existence for many years and has done much good work. Inquiries are now being extended into the whole life and work of a station, and not only into specific aspects. For example, it has been found that in servicing operational aircraft, with a slightly larger supervising staff and tradesmen with the correct skills, considerable savings in man-power can be effected. Arising out of the discovery of a desire to have the technical and administrative wings on the airfield broken down into squadrons, experiments are being made with technical squadrons, signal squadrons, engineering squadrons, and so on, which have indicated that morale as well as efficiency are thereby improved. The application of these conclusions in a much bigger way on operational airfields is now being investigated by the Man-power Utilization Committee. Senior staff are also being sent to make special studies of work methods, not only in the Royal Air Force, but also in industry, and in this work they are having the help of young national service officers with honours degrees in scientific subjects, who were helping to work out the techniques.

Mr. Birch believes that the experience drawn from industry can have solid and substantial results in saving man-power and increasing efficiency, and that as a result of all these experiments it should be possible during the next two or three years to save some thousands of posts. He referred also to the need for very highly trained technical officers which is being met by the Technical Cadet Scheme, and by the postgraduate training of serving officers, for example, in the postgraduate course in guided weapons. The real background of the Royal Air Force was, and will remain, however, the general duties officer, and the period of training at Cranwell has been extended to three years, first to enable the cadets to finish their training in jet aircraft, and second, to ensure that they have a good general education as well as a technical one.

Mr. G. S. de Freitas, while welcoming this reference to scientific research into man-power, and referring to the need for increasing the supply of scientists and technologists, as well as reducing unnecessary demands on the limited resources in Britain of skill and materials, suggested that more attention to human relations in the Royal Air Force is also required. There was little other reference in the debate to what is already being done in the Royal Air Force to save man-power, although there was general recognition of the importance of deploying wisely scientific and technological man-power and increasing its supply so far as possible. Dr. A. D. D. Broughton, in supporting the idea of an exchange of technicians between the Service and industry, stressed the importance of keeping a careful watch on the competition for technical man-power between the Services and industry.

Recent Earthquakes in Lebanon

A swarm of earthquake shocks, of which four were strong, occurred on the night of March 16, and the following day. The epicentres were in the south of Lebanon, where considerable damage was done in some forty villages. Reports so far received state that 112 people are known to have been killed and more than a hundred injured. Considerable apprehension was caused, and thousands of people gathered on the shore, away from buildings. Minor earth tremors have been known to occur in Lebanon, but large shocks are infrequent there. The larger earthquakes are more frequent in southern Turkey.

Preparation of Illustrations for Publication

Illustrations in the form of drawings or graphs are often the most important feature of a scientific paper, and many research workers with little or no previous experience in the matter sometimes unwittingly cause considerable extra trouble and expense in editorial offices by submitting illustrations which require a great deal of alteration before they are suitable for reproduction. Most journals have their own peculiarities, and before submission of a paper intending authors should examine the particular journal they have in mind to see, for example, if any particular form and size of lettering is favoured (many journals prefer to set up letters and numbers in actual type when these occur outside the block).

However, as a general guide, intending authors (even senior ones) could not do better than consult "Notes on Preparation of Illustrations", prepared by the editorial office of the *Biochemical Journal* (price 1*s*., from the Lister Institute of Preventive Medicine, Chelsea Bridge Road, London, S.W.1). This gives simple instructions, and goes on to consider a typical graph. It shows the graph drawn incorrectly, then as it should have been drawn, and finally as it would appear when published. The points discussed are really based on common sense alone; but the pamphlet does emphasize in a particularly direct way the essentials of the matter, and its acquisition by departments and/or individuals for the modest outlay of a shilling is a worth-while investment.

Stress Analysis Group of the Institute of Physics: Annual Conference

THE summarized proceedings of the ninth annual conference of the Stress Analysis Group of the Institute of Physics, which was held in the University of Sheffield during September 28–30, are printed in the January issue of the *British Journal of Applied Physics* (7, 1; 1956). The opening lecture was delivered by D. G. Sopwith (Mechanical Engineering Research Laboratory, East Kilbride), who spoke on the application of stress analysis to the design of some engineering components. Dr. Sopwith outlined the pattern that any design investigation should follow and emphasized that the stress analyst's task is not finished until the results are presented in a form such that the designer can apply them directly to the particular problem under consideration. Four papers by members of the Engineering Department of the University of Sheffield dealt with the measurement of residual stresses in cold-drawn tubes; the effect of tensile overstrain on the yield criterion for mild steel, brass and copper; extrusion under drop-hammer impact; and stress-strain characteristics of metal at high rates of strain, respectively. D. A. Drew (Rolls-Royce, Ltd., Derby) discussed the measurement of aircraft engine vibration in flight and pointed out that, though great accuracy is not vital, the measuring system has to be capable of dealing with frequencies up to 15 kc./s. Other papers dealt with strain gauges; the use of the resistance-network analogue for solving plane stress problems; machining stresses in turbine blades; and the application of the frozen stress method of photo-elastic analysis using 'Araldite' resin models to the study of the stresses in the T-junction of a branched pipe. In addition, a series of short papers presented by R. G. Boiten (Institut T.N.O. voor Werktuigkundige Constructies, Delft), describing the work of his organization, are of particular interest; they included descriptions of the photoelastic bench at Delft, work on prefabricated strain gauges, and a new type of brittle lacquer the raw material of which consists of plumber's resin.

Refugia Indicated by Pollen Profiles

C. H. HEUSSER has given an account of some interesting pollen profiles in the Queen Charlotte Islands, British Columbia (*Canadian J. Bot.*, 33, 5, 429; 1955). In all, five peat sections were examined from muskegs in different islands of the group with the primary purpose of reconstructing the post-glacial plant succession and associated climatic and physiographical alterations. A secondary purpose was to support or disprove the geological and zoölogical data favouring the existence of refugia in which biota survived from pre-glacial or inter-glacial times. The oldest pollen record tends to support this contention. The record is older than any derived from sections heretofore studied on the north-west coast. Twenty-three plant entities are represented in the bottom sediments below the lodgepole pine maximum which in these other sections marks the oldest peat. In addition, 27 per cent of the coniferous pollen at the base of the section is constituted of climax forest trees, thus implying the presence of long-established forest when pollen sedimentation began. The number and kinds of pollen in the basal peat favour the interpretation that vegetation persisted in refugia through at least the last glaciation. The pollen profiles further corroborate earlier findings for changes in land–sea level relations and for the following post-glacial climatic sequence: early cool-moist, warmer and drier (thermal maximum), and late cooler and wetter.

The Neurohypophysis: Symposium in Bristol

THE Colston Research Society, Bristol, has arranged since 1948 annual symposia on subjects appropriate to each of the Faculties in turn of the University of Bristol, and this year the symposium, to be held during April 9–12, will be on "The Neurohypophysis". The subject is one which appeals to a diversity of scientific interests, and the list of invited speakers includes anatomists, biochemists, pharmacologists, physiologists and zoologists. Besides eight speakers from Great Britain, there are three speakers from the United States, two from Sweden and one each from Canada, Chile, France, Germany and Switzerland. The symposium will be under the direction of Prof. H. Heller (Department of Pharmacology, University of Bristol), and Sir Henry Dale will open the proceedings. On April 10 the Society will hold its annual reception, at which the principal speaker will be Sir Lionel Whitby. Further information can be obtained from Dr. R. J. Fitzpatrick, Department of Pharmacology, University of Bristol.

Oversea Service Division, Colonial Office

THE following appointments have recently been made in the Oversea Service Division, Colonial Office: E. W. Momber (assistant director of agriculture, Northern Region, Nigeria), deputy director of agriculture, Northern Region, Nigeria; T. A. Phillips (principal of the School of Agriculture, Northern Region, Nigeria), deputy director of agriculture, Eastern Region, Nigeria; S. T. Hoyle (principal scientific officer, Nyasaland), senior principal scientific officer, Nyasaland; Miss F. M. Roberts (principal scientific officer, Jamaica), principal scientific officer, plant pathologist, Kenya; W. H. Foster, senior scientific officer (botanist and plant breeder), Northern Region, Nigeria; A. M. M. McFarquar, agricultural economist, Western Region, Nigeria; P. Thomas, cocoa soil survey officer, Gold Coast; D. R. Younger, manager, Yumdum Experimental Farm, Gambia; C. F. Hutchison, assistant bacteriologist, Jamaica; J. E. Clarke, entomologist, Game and Tsetse Control, Northern Rhodesia; D. G. Coursey, scientific officer (chemist), Federation of Nigeria; M. G. R. Hart, scientific officer, Sierra Leone; D. W. Brocklesby, veterinary research officer (protozoologist), East Africa High Commission; R. I. C. Hyam, veterinary officer, Northern Rhodesia; W. R. Nunn and L. D. Tennant, veterinary officers, Uganda; D. J. Skinner, veterinary officer, Kenya; Miss M. de Vere Allen, laboratory technologist, Kenya.

Announcements

BRIGADIER J. A. SINTON, V.C., F.R.S., has been awarded the Manson Medal for 1956 of the Royal Society of Tropical Medicine and Hygiene. This Medal is awarded triennially to the living author of such original work in any branch of tropical medicine or tropical hygiene as the Council may consider to be deserving of the honour.

MR. P. R. OWEN, reader and director of the Laboratory of Fluid Motion in the University of Manchester, has been appointed professor of the mechanics of fluid motion in the University.

MR. R. W. MARSH, head of the Plant Pathology Section at Long Ashton Research Station, is being seconded to the Food and Agriculture Organization for the period April–June to report on crop protection methods and organization in Yugoslavia.

A CONFERENCE on starch will be held in Detmold, Germany, during May 2–4, and will consist of three sessions as follows: fundamental research and research methods; starch production and techniques; and starch fractions and derivatives. The conference is organized by the Arbeitsgemeinschaft Getreidesforschung e.V., Detmold, from which further information can be obtained.

FOLLOWING the extremely successful Summer School in Theoretical Chemistry held last year at Oxford, another similar School is to take place during July 7–21, under the direction of Prof. C. A. Coulson. Further particulars can be obtained from the Assistant Secretary, Delegacy for Extra-Mural Studies, Rewley House, Wellington Square, Oxford. Applications should be made before April 30.

THE Chemical Society is organizing a symposium on "Antibiotics and Mould Metabolites", to be held on March 26 in the Great Hall, University of Nottingham. Seven papers will be read and these will be published later as No. 5 in the Society's series of "Special Publications" (8*s*. 6*d*. to Fellows of the Society; 15*s*. to others). Further information can be obtained from the Society at Burlington House, Piccadilly, London, W.1.

THE Society of Chemical Industry is organizing a three-day conference on the "Disposal of Industrial Waste Materials", to be held in the University of Sheffield during April 17–19. The conference will cover a very wide range of materials, including fine chemicals, industrial effluents, slag and ash, and atomic-energy products. The conference is open to all on payment of a registration fee of 2 guineas (10*s*. 6*d*. for members of the Society). Application forms and further information can be obtained from the General Secretary, Society of Chemical Industry, 56 Victoria Street, London, S.W.1.

A SYMPOSIUM on "Vegetable Tannins", organized by the Society of Leather Trades' Chemists, will be held in the Chemistry School, Pembroke Street, Cambridge, during April 12–13. The chairmen during the two days will be Prof. R. D. Haworth and Dr. F. E. King, respectively. The conference is open to all, on payment of a fee of £1. Registration forms, to be returned by March 31, and further information can be obtained from G. H. W. Humphreys, Forestal Land, Timber and Railways Co., Ltd., Forestal Central Laboratories, Harpenden, Herts.

AN international symposium on "Macromolecular Chemistry", under the auspices of the Commission on Macromolecules of the International Union of Pure and Applied Science, will be held in the Weizmann Institute of Science, Rehovot, Israel, during April 3–9. The first half of the symposium will consist of sessions of papers on the following three topics: general behaviour of polymers in solution; general behaviour of biocolloids and polyelectrolytes in aqueous solution; and special polymeric systems in solution. The rest of the meeting will be devoted to tours around Tel Aviv, Haifa and Jerusalem. Further information can be obtained from the Weizmann Institute of Science, Rehovot.

THE fourth and final meeting of the series of meetings on "Nutritional Requirements and Food Fortification", organized by the Nutrition Panel of the Food Group, Society of Chemical Industry, will be held at the Royal Society of Medicine (Barnes Hall), 1 Wimpole Street, London, W.1, on April 11, at 6 p.m., when the subject of iodine and fluorine will be discussed. Iodine metabolism and the iodization of food will first be considered, and the meeting will then turn to physiological and medical aspects of fluorine, including the dental problem and the fluoridation of water supplies. Further information can be obtained from the honorary secretary of the Panel, L. C. Dutton, Virol, Ltd., Hanger Lane, Ealing, London, W.5.

A DEBATE on the motion "That Science can Provide as Good an Education as the Humanities", organized by the Fine Chemicals Group of the Society of Chemical Industry, will be held in the William Beveridge Hall, Senate House, University of London, at 7 p.m., on April 20. The principal speakers will be as follows. *For the Motion:* Dr. R. P. Linstead (rector of the Imperial College of Science and Technology, London) and Prof. A. R. Ubbelohde (professor of thermodynamics in the Imperial College). *Against the Motion:* Mr. B. L. Hallward (vice-chancellor of the University of Nottingham) and Mr. H. D. P. Lee (headmaster of Winchester College). The chair will be taken by Sir William Ogg (director of the Rothamsted Experimental Station and immediate past-president of the Society of Chemical Industry). Admission will be by ticket, obtainable from the honorary secretary of the Group, Dr. J. D. Kendall, Ilford, Ltd., Ilford, Essex.

THE essay subjects for this year's *Endeavour* Prizes of the British Association for the Advancement of Science will be as follows: research in polar regions; scientific aids to archæology; the story of steel-making; the chemistry of big molecules; new elementary particles; the control of plant diseases. The essays must be sent in by June 1 and should not exceed four thousand words. Competitors must be less than twenty-five years old, and the Prizes will be 50, 25 and 15 guineas, respectively, with two special awards of 5 guineas to those less than eighteen. Further information can be obtained from the Assistant Secretary, British Association for the Advancement of Science, Burlington House, Piccadilly, London, W.1.

ERRATUM.—In the biographical note on Edward Goodrich Acheson in the issue of March 3, p. 412, the United States Patent Office was incorrectly referred to as the United States Post Office; the Patent Office exhibited one of E. G. Acheson's patents, among seventeen which were considered to have most benefited mankind, and not seventeen of Acheson's patents, as stated.

SNOW ACCUMULATION AND ABLATION

THE mass of snow and ice stored at high elevations on the Earth is a large reservoir of the hydrological cycle. Any reduction in its mass by melting releases potential energy, and the debts of past climates become discharged. We have neither made much use of this energy nor made a serious attempt to measure its size or its fluctuations. Even the mass of water accumulated in annual snowfields is measured only in a few places, and yet its sudden release in a thaw is often the source of a disastrous flood; for example, the 1950 Red River flood at Winnipeg. If the snow stored in the upper catchment area of the River Severn were known and the relation between its ablation and the weather were established, it would be possible to predict the likelihood and the size of the flood lower down the river. Unfortunately, however, snow accumulation and ablation are not easy to measure, and we have almost no knowledge of the quantity of water lying as snow in any catchment area in Britain.

The discussion meeting on "Snow Accumulation and Ablation", organized jointly by the Royal Meteorological Society and the British Glaciological Society and held in London on January 18, was concerned mainly with the problem as it affects the budget of glaciers. Even in Britain, glaciers are of interest; for as one speaker (L. C. W. Bonacina) remarked, there would be glaciers in Scotland after fifty summers—not winters—like that of 1951.

It is well known that European glaciers are retreating in association with the warming of the climate. Their retreat is measured in the simplest way by recording the annual change in the position of the glacier tongue. This measurement merely indicates that the glacier is striving to balance its income, the total accumulation, against its expenditure, the net ablation; but it reveals neither the sizes of its budgetary items, nor which climatic variable dominates its retreat. For that purpose it is necessary to measure the annual changes in the glacier mass both in the higher parts where there is a surplus (the net accumulation) and at the lower levels where there is a deficiency (the net ablation). This will show whether the retreat is associated with decreased precipitation or with increased atmospheric heat causing greater ablation. Then it is necessary to investigate the heat balance at the glacier surface to discover the importance of the various meteorological factors causing the ablation. All the heat sources and sinks at the glacier surface have to be measured: the net radiation, the convection from the air, the conduction from the glacier, the evaporation and the condensation. This task is similar to estimating the heat balance at the ground surface, with the one simplification that the snow surface remains at 0° C. whenever melting occurs.

Such investigations of the mass and heat budget of a glacier are difficult undertakings, and it is not surprising that only a few studies have been made. The observations of Ahlmann and Eriksson in North East Land in 1931 were analysed by Ångström[1]. An intensive study of the heat balance over a glacier surface was made by Sverdrup[2-4], Ahlmann and Olsson on Isachsen's Plateau in Spitsbergen in 1934. Sverdrup's findings were used to obtain some idea of the relation between ablation and climate on the Vatnajökull in Iceland by Ahlmann and Thorarinsson[5], and these findings were also applied to observations on the Fröya Glacier in East Greenland by Eriksson[6]. The most exhaustive study has been made by Wallén[7] on the small, but accessible, Kårsa Glacier in Swedish Lapland. This is the only study that has covered a number of consecutive years (1942–48), and it was concluded that the principal cause of the recession of the glacier was increased ablation associated with increased summer temperature and humidity, and a longer ablation season. More recently, Baird[8], Ward[9] and Orvig[10] have made the first studies in the Canadian Arctic on two ice caps in Baffin Island, and observations have been made on the ice shelf of Queen Maud Land in the Antarctic[11]. (An ice shelf is a coastwise glacier composed of land ice, sea ice and local snow, generally floating on the sea.)

The discussion at the meeting was opened by R. A. Hamilton, of the British North Greenland Expedition, who gave a brief description of the geography and glaciology of the Greenland ice cap and of its dominant weather systems.

H. Lister, another member of the Expedition, followed with a detailed account of his measurements of the ablation and of the heat balance during the melting season made on one of the glaciers flowing from the Greenland ice cap. The practical difficulties of using normal meteorological instruments to measure the gradients of temperature, vapour pressure and wind speed over a polar glacier surface were well illustrated. The many meteorologists present must have been convinced of the need for the development of more suitable instruments for reliable work in cold climates. The subject of heat transport through the air has been one of much controversy during recent years in the light of current ideas on turbulence and there is a feeling that the Greenland ice cap is not a convenient place to delve into detailed research on this problem; it can be pursued more profitably on the snowfields of the Cairngorms, for example. Such a site would be suitable also for development trials of instruments and for determining the optimum observations required for a study of heat balance. It is gratifying to record that P. D. Baird, of the University of Aberdeen, has made a start in this direction, with the help of the Meteorological Office, by establishing a weather station on the Cairngorm plateau this winter.

W. H. Ward spoke generally of the problems of the direct measurement of snow accumulation and ablation in the light of his experiences on two ice caps in Baffin Island, Canada. The long-term seasonal measurement of accumulation and ablation was not too difficult and was easiest in the ablation zone of a glacier. It was a question of measuring the change in the mass of water relative to a suitable reference horizon, and the dense ice surface in the ablation zone was a convenient reference. But in the thick permeable accumulation zone it was sometimes impracticable to reach a reference level through which some melt water did not seep and re-freeze at a lower level. When accumulation and ablation occurred intermittently, it was difficult to define the duration of the ablation season.

Daily measurements of ablation and accumulation are of greater interest to the meteorologist, and the usual methods of measurement are subject to many errors. The ablation is frequently measured by the lowering of the surface relative to a stake sunk in the snow, and the change in level is multiplied by a density to give the ablation in, say, inches of water. But the surface can settle for a variety of reasons. Compaction can occur without ablation, melt water descending through subsurface snow can cause compaction beneath a frozen snow surface and radiation can cause melting below the surface. Furthermore, the snow density varies irregularly with depth. Constant watching of the snow and the weather cannot eliminate all sources of error. In the accumulation area of a glacier during the melting season, the total mass of ice and water can be measured by sampling every snow layer from a pit dug to a suitable reference level. The density of each sample and the thickness of each layer are measured and their products summed up. That task may easily take a full day's work. The water content of all the samples can be measured by calorimetry, but it is an impossible task in a deep profile.

These are the methods of measurement available at present, and there is a pressing need to develop a simple field-method of recording separately the total masses of water and ice in a melting snow profile.

W. H. WARD

TESTING OF METALS BY OPTICAL METHODS

On January 13 a symposium, at which there were some sixty participants, was held at the Institute of Physics, London, on "The Possible Uses of Surface Methods as a Means of Testing Metals (with Special Reference to Optical Methods)". This was sponsored by the Non-Destructive Testing Group of the Institute of Physics, and it was to be understood that only non-destructive methods were to be discussed. The symposium was opened by Prof. S. Tolansky, of the Royal Holloway College, University of London, Dr. O. S. Heavens, of the University of Reading, and Dr. R. W. B. Stephens, of the Imperial College of Science and Technology, University of London, who each in turn gave a half-hour discourse on selected topics, after which the meeting was thrown open to general discussion. The chair was occupied by Dr. J. Thewlis.

In an introductory survey, illustrated by some forty slides, Prof. Tolansky selected as typical subjects for examination some of his own studies on the optical testing of surface finish, of microtopography in general, the examination of micro-hardness and directional hardness, the character of electrodeposits and the examination of machined metal surfaces. Attention was devoted to five different methods of approach which he uses for the study of surface structure. There is first two-beam interferometry, which is capable of extensive application; then, for increased precision, indeed reaching down to structural features the heights of which approach crystal lattice dimensions, there is multiple-beam interferometry in a variety of forms, examples of which were shown. It was stressed that the great resolutions attainable are only in the height–depth dimension and not in extension across the surface. Experiments revealing the perfection of contour of the silver layers used in multiple-beam interferometry were described. The light-profile microscope was then illustrated, and it was emphasized that this has very obvious metallurgical applications, some of which were shown. The advantage of this system is that it is capable of resolving an elementary cube of side (roughly) half a light-wave. Thus in effect a useful magnification of about a thousand is available in three dimensions, and this is of much value in many problems. A simple optical shadow-casting technique was then described and possible applications discussed.

Finally, a review was included of a critical experimental examination intended to test the validity of the method of total reflexion advocated for the exploration of engineering bearing surfaces. In this, a hypotenuse of a right-angled prism is pressed on to the surface and at the points of contact total reflexion is interfered with, revealing thus a dark pattern. Some difficulties in interpretation were discussed.

Dr. Heavens then reviewed the development of recent studies of surface reflectivity and of the assessment of surface films and oxide films on metals. He pointed out that electromagnetic theory enables the optical constants of a material to be deduced from observations on light reflected from a surface. The theory is simple for the ideal theoretical case of a plane boundary separating homogeneous, isotropic regions. Thus accurate experiments can yield information on the nature of a real surface from the difference between such observations and the computations of the theory for the ideal case. In the case of transparent materials, the presence of a transition layer at the surface is revealed by a gradual, rather than abrupt, differential phase-change in the light reflected from the surface. For heavily absorbing materials, the optical constants are easily deduced from polarimetric observations. Since the depth of penetration in these cases is a small fraction of a light-wave, then these observations yield information about the surface layers only and cannot easily be adapted to the problem of examining the bulk properties. Simple criteria exist, however, enabling the homogeneity of the surface layers to be checked.

The problem of examining surface roughness was then discussed by Dr. Heavens. He indicated that this may be tackled by a number of different reflexion methods, according to the scale of the roughness involved. For very rough surfaces (irregularities of many wave-lengths) he described scattering methods as useful. By judicious selection of the wave-length a wide range of roughnesses may be covered. Irregularities of the order of a wave-length may be examined by two-beam interference methods, such as are widely used in the optical industry. Under this heading, the interference microscope, coupled with replica techniques, was mentioned. It was then stressed that for surface roughnesses much smaller than a wave-length there are two notable methods, namely, multiple-beam interferometry which can be applied to a wide range of surfaces, both transparent and absorbing, and, for specialized applications, phase-contrast methods. Both these methods enable a very high resolution normal to the surface to be attained.

Although much information may be obtained by a detailed analysis of the state of light reflected from a surface, methods suitable for non-destructive testing tend to be restricted to those which are reasonably simple to make and to interpret.

The third formal contribution, by Dr. Stephens, was devoted mainly to suggesting future possible extensions of techniques. It was pointed out that, as a general assessment, the application of optical reflexion methods is mainly dependent on the provision of good reflecting surfaces. Since for opaque materials the light-wave penetrates only to depths of the order of a few hundred angstroms, considerable care is necessary to avoid any treatment of the surface which might alter appreciably its physical characteristics as compared with the bulk material. The use of obliquely incident light minimizes the effect of small surface blemishes, and radiation wavelength is another factor at our choice. In testing for a high surface polish, it would be desirable to use the shorter ultra-violet wave-lengths; but when the object is to standardize the material itself, then longer wave-lengths are to be preferred. Dr. Stephens then directed attention to the recent advances in infra-red detectors—the photoconductive cells with their very small time-constants which provide new possibilities in non-destructive testing. Moving farther along the electromagnetic spectrum to the microwave region, the use of these centimetre waves offers an advantage in reflectivity measurements from the aspect of less exacting requirements in surface smoothness, and furthermore, by changing the frequency, the effective depth of penetration can be conveniently varied. Dr. Stephens here emphasized the advantage of such studies over methods using visible light, which are confined effectively to surface layers.

Recent work on the fundamental properties of surface electromagnetic waves has indicated another possible line of approach to the investigation of surface properties. These, Sommerfeld or Zeeneck waves, are attenuated both in the direction of propagation and normally to the surface to an extent dependent on the reactance of the surface, and are thus sensitive to geometrical irregularities and surface composition. Another approach in surface testing which Dr. Stephens thinks may merit attention is to investigate optically the effect of applying a second physical agency to the specimen, for example, a magnetic field, as in the Kerr magneto-optic rotation effect.

The three formal surveys were succeeded by a lively discussion to which many of the audience contributed. An appreciable fraction of the available time was taken up with a discussion of the reliability of replication methods, contributions being made by Dr. J. Thewlis, Miss K. B. Day and also Prof. Tolansky, who expressed the view that he has experimentally established that some materials can be used for making replicates with very high fidelity in extension, but yet simultaneously with appreciable uncertainty in depth. Mr. J. C. Kelly raised the issue of the relative perfection of contour of vacuum-deposited silver and vacuum-deposited dielectric multilayers. This matter received appreciable discussion.

The novel surface-penetrating methods proposed by Dr. Stephens aroused much interest and several queries about such procedures were posed.

Several members present were surprised at the extreme sensitivity of the polarization methods advocated by Dr. Heavens.

It was clear from the vigour of the discussion that the symposium had justified itself and focused attention in a practical way on a wide variety of techniques available to those who must needs examine metals in a non-destructive fashion.

PHOSPHOLIPIDS IN FOODS

A CONFERENCE on recent advances in the knowledge and uses of phospholipids in foods, arranged jointly by the Food Group and the Oils and Fats Group of the Society of Chemical Industry, was held in London during February 9–10 at the Wellcome Research Institution. The opening session, under the chairmanship of Prof. T. P. Hilditch, was concerned with the chemistry and physical chemistry of phospholipids. Papers were presented by Prof. T. Malkin and Dr. B. A. Pethica. The afternoon session, at which Dr. K. A. Williams took the chair, was devoted to consideration of methods of separation. Dr. June Olley described methods of counter-current distribution, and Mr. D. N. Rhodes' chromatography. A third paper, on deteriorative changes in food phospholipids, was presented by Dr. C. H. Lea. During the first half of the second day, two papers were presented: one by Dr. J. A. Lovern on phospholipids in fish, and the other by Dr. F. Aylward on plant phospholipids, the chairman being Dr. A. J. Amos. The final session, under the chairmanship of Prof. A. C. Frazer, was also introduced by two papers: Dr. J. N. Hawthorne spoke on animal phospholipids, and Mr. H. H. Hutt on the large-scale production and industrial uses of phospholipids.

The papers were full of interesting information and covered a wide range, from relatively abstruse and detailed chemistry and physical chemistry to technical points concerned with large-scale production. Discussion was lively and varied in each session. It was apparent that things are moving on the chemical side. A wider range of pure synthetic phospholipids is likely to be available in the near future. This should lead to greater and more accurate knowledge of the physical chemical properties of this group of substances. Once this information begins to become available, many fascinating problems in the biological field, especially those associated with the structure and functions of lipoproteins, are likely to open up. The importance of close co-operation between chemists, pharmacologists, biochemists and nutritionalists in this field cannot be over-emphasized.

Work on phospholipids in foods is still in a formative stage, but methods of isolation and identification are rapidly developing. The importance of phospholipids in relation to deteriorative changes in food is well recognized. They may also play an important part in relation to some of the attractive properties of foods that technologists may wish to retain or enhance. This conference concerned itself mainly with the chemical and physical chemical background, with the occurrence of phospholipid in natural materials and the technological uses to which phospholipids may be put. There is clearly considerable scope for the use of phospholipids in food technology. However, the biological effects of separated and prepared phospholipids used in food out of their normal context will require careful examination. With increasing knowledge and improving techniques in this field, it should soon be possible to make a more accurate assessment of the importance of phospholipids in the diet to health and nutrition. We may confidently expect considerable advances in this field during the next ten years, and it is encouraging to see such a wide interest taken in the subject at this early stage.

FULBRIGHT PROGRAMME IN GREAT BRITAIN AND COLONIAL TERRITORIES

FIFTH REPORT

THE fifth annual report on the Fulbright Programme in Britain and Colonial Territories* takes the form of a review and appreciation of the work of the Commission during 1949–54. To this Senator J. W. Fulbright himself contributes a foreword, while there are reviews from the American side and from the British side by Herbert Agar and Dame Lillian Penson, respectively, an article on "Orientation" by Sir Alexander Gray describing what is done to introduce the newly arrived scholars, and a series of articles on special features of the Programme. Sir Raymond Priestley deals with the Colonial programme, Mrs. L. M. Cochrane with the "Special Categories", Dr. S. C. Roberts with the American Studies Conference and Dr. E. A. Ford with the Interchange of Teachers Programme. There are also the usual general appreciations of the work of the British scholars in America and of American scholars in Britain, this year by Dr. F. A. Young and Dr. A. L. Goodhart, respectively, followed by comments from selected lecturers, advanced research scholars, supervisors and graduate students. Besides a summary of awards since 1949, there are appended a directory of Fellows for 1949–54 and an analysis of fields of study and research during 1953–54.

Of the 674 awards in 1953–54, compared with 732 in 1952–53, 329 were to United States and 345 to British citizens, the 1952–53 figures being 349 and 383, respectively. Of those to United States citizens, twelve were to visiting lecturers to British universities, eighteen to advanced research scholars and 163 to graduate students; eleven awards were made in the special categories group; fourteen for visiting lecturers, research scholars, school teachers or graduate students in the British Colonial Territories, and a hundred travel grants were again made to primary and secondary school teachers for exchange under the Anglo-American Teacher Interchange, the remaining eleven awards being to lecturers for the American Studies Conference. The travel grants to British citizens likewise included one hundred to school teachers under the Anglo-American Teacher Interchange, seventy-eight to advanced research workers, visiting lecturers and teachers and 167 to graduate students. The anticipated 350 awards to United States citizens and 384 to British citizens in 1955–56 will bring the cumulative total since 1949 to 4,842. Analysed by fields of study and research, the subjects claiming most awards in 1953–54 were chemistry (26 British and 13 American), education (13 and 3), history (16 and 23), literature (16 and 44), mathematics (11 and 4), physics (12 and 6), medicine (20 and 2), engineering (23 British) and dentistry (12 British).

Originally, the prime concern was to place the scholars in the universities of the United Kingdom; but it was contemplated from the beginning that there should be a counterpart to the reception of American university teachers and students in British universities in the form of travel grants for British lecturers and students to go to the United States, and on both sides applications have always vastly exceeded the number of possible awards. Nevertheless, the Commission has not been prevented from branching out in new directions, and in her review Dame Lillian Penson stresses the particular value of the creation, as a result of Sir Christopher Warner's proposal, of a Special Citizens' section in the Commission's budget which has enabled the Commission to spend a part of its resources in effecting contact between such groups as social workers and extramural tutors. The grant towards the expenses of the teachers in secondary schools exchanging with one another under the scheme for teachers interchange is another development from the original programme, as is the grant made annually for the past three years towards the organization and maintenance of an American Studies Conference at either Oxford or Cambridge in late July or early August to discuss aspects of academic disciplines of interest on both sides of the Atlantic.

Dame Lillian, moreover, lays special stress on the gradual development during recent years of the Colonial programme, in which there is still room for further growth and experiment. The Colonies themselves have welcomed with enthusiasm the seconding to them of the American scholars, and Dame Lillian believes it would be difficult to exaggerate the importance, at this stage of evolution, of the presence of American scholars in these centres of research or teaching. Reviewing this programme in more detail, Sir Raymond Priestley notes that the Commission has now decided to increase to more than 25 per cent the 10–15 per cent of the annual budget expenditure previously devoted to this purpose. Reports made by the American visitors to the Colonies show how significantly these visits are serving the general aims of the Fulbright Programme in promoting international understanding; and although it is too early to assess the contributions to learning which have stemmed from the visits, it is not too early to record the indebtedness of Colonial institutions to the services rendered by their guests. The Royal University of Malta, for example, has profited greatly from the teaching in English literature and in history by a series of Fulbright professors. The administrative problems of the Colonial programme are well on the way to solution in view of the enthusiastic response from the Colonial schools and teacher-training colleges to the initiation in 1952–53 of grants for American school teachers to work in schools and training colleges in the Colonies, and the Commission has decided to use a substantial part of the increase in its Colonial budget for this purpose.

---

* Fifth Annual Report of the Fulbright Program in the United Kingdom and Colonial Territories, 1949–1954. Pp. 184. (London: United States Educational Commission in the United Kingdom, 1955.)

Describing the Special Categories programme, Mrs. L. M. Cochrane outlines the reasons which led to the selection and visit of a social work survey team whose five members have covered the fields of delinquency (adult and juvenile offenders); family and child care; organization and administration of public services; group work and community organization; and health and rehabilitation. This visit was the outstanding event of 1954: the personal relationships established wherever the members of the team went were extremely successful, and the full written report was to be presented in 1955. The visit has already led to the suggestion that a similar team should survey adult and workers' education and that the Commission should sponsor research teams to visit British Colonial areas; in commenting generally on the British scholars in the United States, Dr. F. A. Young emphasizes that the special categories, broadly speaking, are an investment in adult education, both as a mean of cultural diffusion and as a form of social service which has generated a cluster of rapidly emerging professions including workers' education, social work, library service, museum technology and educational broadcasting. He points out that the visiting scholars in this section move outside the well-worn academic paths and are continuously discovering much that to them is new and exciting. They seem to be nearer to the everyday life of Britain and come closer to the heart of the United States. Accordingly they are in many ways more effective interpreters, promoting understanding where it is most needed, at the base rather than at the apex of our social structure. The large part they have played in the advancement of scholarship and international understanding, writes Dr. Young, is the basic achievement of the British scholar in America; and elsewhere in the report Prof. Una Ellis-Fermor expresses the view that the Commission has given timely help to young and promising scholars visiting Britain who will in all probability be among the leading university teachers of the future.

CENTRAL LABORATORIES FOR SCIENTIFIC AND INDUSTRIAL RESEARCH, HYDERABAD

REPORT FOR 1954

THE annual report for 1954* of the Central Laboratories for Scientific and Industrial Research, Hyderabad, the new buildings of which were formally opened by Pandit Nehru on January 2, 1954, includes the usual lists of papers published during the year and of staff. Two more pilot-plant buildings were due to be constructed in the following year. In the Oils Section, besides investigations on local bleaching earths, samples of triricinolein and sodium ricinoleate were prepared, as well as castor-oil-modified alkyds of 40 per cent, 50 per cent and 60 per cent oil length by the monoglyceride. Work on dehydrated castor oil included its utilization in the preparation of industrial finishes, while studies continued of the antioxidant properties of catechin in fats and oils and of factors affecting the refining of cottonseed oil. In the Entomology Section, work has proceeded on a number of lines: the pharmacological action of the portion of *A. squamosa* seed-oil insoluble in petroleum ether, using the frequency of the isolated heart of the cockroach; the insecticidal properties of chlorinated turpentine against *B. chinensis* and *T. castanium*; the anti-oxidant properties of catechin against pyrethrum; and the insecticidal properties and spreading pressure of various indigenous oils. The Fibre and Paper Section has been occupied chiefly in putting the pilot-plant project for making hand-made paper on a regular production footing, and the report of the Laboratories is printed on hand-made paper produced by the Section. A comparative study of different types of paper led to improvements in the quality of several types produced by the Section.

The Fuel Section continued its work on the briquetting and the low-temperature carbonization of non-caking Indian coals and on the products of low-temperature carbonization, and its systematic survey of the coalfields of Hyderabad State. In the Heavy Chemicals and Fertilizers Section the utilization of felspar and iron pyrites received further attention, as well as the production of sulphur dioxide from gypsum, while preliminary work was carried out on the preparation of hydrazine hydrate; studies continued in phosphate fertilizers and the preparation of active carbon from vegetable waste materials and from a low-temperature coke. The systematic study of Hyderabad clays continued in the Ceramic Section, and in the Organic Chemistry, Pharmaceuticals and Drugs Section, besides work on Indian turpentine, eucalyptus oil and alkaloids from *Strychnos nux-vomica*, investigations proceeded on the preparation of compounds with œstrogenic activity and of insecticides from phenol and its ether. A number of quinazolines have been condensed with magnesium phenyl bromide to give 3 : 1 : 4-benzoxazines, and some of them were being examined further for hypnotic action. The synthesis of the analgesic, methyl dihydromorphinone (metopon), was being continued on a larger scale.

In the Biochemistry Section the yield of citric acid by fermentation of molasses has been increased by supplements of 0·5–2 per cent of methyl or ethyl alcohol, and further work on the itaconic acid fermentation has confirmed that glycolysis is the initial sequence from sucrose and that the presence of arsenite induces the mould to accumulate keto acid. The oxidation of glucose to gluconic and 2-keto-gluconic acids by *Pseudomonas fluorescens* was studied in greater detail, and an exhaustive examination made of the amino-acids of the protein from the seed-cake *Annona squamosa*. X-ray studies of Indian clays were continued, and in the Physical Chemistry Section the conductivity of sulphuric, nitric and hydrochloric acids in binary mixtures of methyl or ethyl alcohol, acetone, and dioxan with water was determined. Pilot-plant work in the Chemical Engineering Section included the pretreatment of cotton seed, the preparation of dehydrated castor oil and the fractionation of fusil oil on the 'Quickfit' all-glass vacuum distillation unit, while the Section also continued to study the solvent extraction of oil cake and the condensation of saturated vapours. The Operational Research Section examined the possibilities of utilizing pectin in the fruit-preserving industry and the utilization of amosite asbestos fibre for asbestos cement sheets.

COMPRESSED AIR HYGROMETER FOR MEASURING FROST POINT IN THE STRATOSPHERE

THE most satisfactory method of measuring the water vapour content of air in the stratosphere, where the frost point is −75° C. (−103° F.) or less, is to determine the frost point with the Dobson–Brewer frost-point hygrometer carried in an aircraft. In this apparatus the water vapour in the air is condensed as ice on the outside of a thimble cooled internally by cold petrol (cooled by a mixture of petrol and solid carbon dioxide) or by liquid air. The observer adjusts the rate of flow of the cooling liquid and notes the temperatures at which the ice deposit increases and decreases. The mean of these two temperatures is taken as the frost point; there may be an interval of 5–10 deg. C. between them. As the frost point is reduced, the ice deposit becomes thin and more difficult to see and, finally, at frost points below −85° C. (−121° F.) the ice becomes glassy and cannot be seen at all without special optical aid.

Dr. A. W. Brewer (Clarendon Laboratory, Oxford) suggested that the effective range of the instrument could be effectively increased by compressing the incoming air before it reached the hygrometer. Compression raises the frost point, as can be seen from the fact that the humidity mixing-ratio (grams water vapour per kilogram of dry air) is unchanged by the compression. The mixing ratio at the low vapour pressures concerned is proportional to e/p, where e is the vapour pressure and p the air pressure. The ratio e/p is constant in compression so that a ten-fold increase in pressure increases the vapour pressure in the same ratio. This produces an important increase in frost point. Thus, if air with a frost point of −85° C. at the pressure of 115 mb. prevailing at about 50,000 ft. is compressed to 1,014 mb., the mean air pressure at sea-level, its vapour pressure is increased from $23 \cdot 53 \times 10^{-5}$ mb. to $2 \cdot 0757 \times 10^{-3}$ mb. and its frost point correspondingly increased to −71·5° C. (−96·7° F.). A frost point of about −70° C. is much more easily measurable than one of −85° C.

Mr. P. Goldsmith (Meteorological Research Flight of the Meteorological Office) has proposed (*Quart J. Roy. Met. Soc.*, October 1955, p. 607) the use of the engine compressor of a jet aircraft as the source of compressed air. The system has been used on both Ashton and Canberra aircraft, and satisfactory agreement obtained with frost points measured by the normal method. The compressor provides air compressed to a pressure of six to eight times the external air pressure. Goldsmith's article describes in detail the working of the apparatus.

Using this instrument, thirty-five ascents were made from South Farnborough by the Meteorological Research Flight during 1954 to measure frost point in the stratosphere at heights up to 50,000 ft., and the results are given in a paper by R. J. Murgatroyd, P. Goldsmith and W. E. H. Hollings (*Quart. J. Roy. Met. Soc.*, October 1955, p. 533). The compressed air was used above 30,000 ft.; at lower altitudes there is a danger that the high pressure and temperature of the compressed air would damage the hygrometer. They found the frost point decreased steadily with height through the troposphere and that there was usually no change in the rate of fall at the tropopause. In the stratosphere the rate of decrease of frost point decreased with height, and sometimes there was a discontinuity of the rate of fall a few thousand feet above the tropopause. At heights of 10,000 ft. to 15,000 ft. above the tropopause the frost point became almost constant at a value of −82° C. (−115·6° F.) to −85° C. The value was the same in summer and winter. The air here is very dry, having a relative humidity with respect to an ice surface of only 1 per cent. The humidity of the stratosphere is important in the study of the flux of long-wave radiation and of the large-scale circulation of the atmosphere. It is believed that such low humidities are only explicable on the supposition that the air has come from the equatorial stratosphere, being warmed as it does so.

WELDING OF ALUMINIUM AND ITS ALLOYS

THE welding of many commercial aluminium alloys is rendered difficult as a result of their tendency to crack at temperatures above the solidus, or in other cases at much lower temperatures during the cooling of the weld. In 1944 the light-alloy industry initiated a comprehensive series of researches on this problem at the University of Birmingham, the investigations being started under the supervision of the late Prof. D. Hanson and continued under Prof. L. Aitchison. The Aluminium Development Association, in its Research Report No. 27*, has now published a summary of the work of this research team during 1944–50. This quite admirable publication, prepared by Dr. W. I. Pumphrey, a former leader of the team, summarizes the principal investigations and conclusions of the twenty-six papers which have been published.

It was first necessary to develop a hypothesis to explain the high-temperature cracking, and it was shown that on heating to the solidus temperature the ductility fell to zero and the strength dropped rapidly but did not disappear entirely until some higher temperature, still below the liquidus, had been attained. This latter fact was found to be of prime importance, and the temperature above the solidus at which the strength finally disappears emerged as a major factor in the elucidation of the problem.

The development of tests to reveal the susceptibility to both high- and low-temperature forms of cracking was essential to the continuation of this work, and such tests, applicable not only to welds but also to castings, have been developed and are described. The low-temperature form of the defect is connected with the ductility of the material and, in particular, with the nature and mode of occurrence of the brittle intermetallic compounds. Where the weld is under conditions of severe restraint, the presence of these compounds in an intercrystalline form is clearly a source of great weakness.

The other main objective of the work was the development of alloys with good welding and mechanical properties, and three series—the aluminium–copper–silicon alloys, those of aluminium with zinc and magnesium and those with zinc, magnesium and copper—are specifically considered. The tests devised permit the materials to be given at any rate a quasi-quantitative value, and, from this, cracking diagrams have been drawn up for a number of binary and ternary alloys together with the quaternary aluminium–copper–magnesium–silicon and aluminium–magnesium–silicon–manganese alloys; in one case, aluminium – zinc – magnesium – copper – manganese, a start has been made on a quinary series.

---

* Aluminium Development Association. Research Report No. 27: Research into the Welding of Aluminium and its Alloys: a Summary of the Work of the A.D.A. Welding Research Team at the University of Birmingham, 1944 to 1950. Prepared by Dr. W. I. Pumphrey. Pp. 60. (London: Aluminium Development Association, 1955.) *7s. 6d.*

The work has most clearly justified the time and money expended on it, and this publication provides a first-rate summary of the results which have been obtained.

F. C. THOMPSON

A RARE *CRYPTOMERIA*

YAKU-SHIMA, an island about thirty-seven miles off Kyushu, Japan, and covering approximately 190 square miles, is famed for the forests that cover its steep mountain-sides and for its abundant wildlife, especially deer and monkeys. The really unique and outstanding feature of the island, however, is the *Cryptomeria japonica* or 'Yaku-sugi' trees that are found there. These can be compared with the world's most spectacular trees, both because of their size—they grow to 16½ ft. in diameter and 117 ft. high—and their age, which is calculated to be between 1,000 and 3,000 years old. Their classification in systematic botany is not clear, although they are believed to be the ancestors of the Japanese species of *Cryptomeria*, in spite of differing from them both morphologically and ecologically. At one time there seems to have been a mysterious gap in the species' ecology, due either to its requirements or the conditions it was subjected to, as no trees are to be found between four hundred and eight hundred years old; they are all either older or younger. The Yaku-Shima virgin forests are of great interest, for the Yaku-sugi trees grow there along with firs, hemlock and Yamagurumas (*Trochodendron aralioides*, Sieb. et Zuce), and fill the island's valleys with tall trees decorated with intertwining epiphytic and parasitic plants.

At present, negotiations are going on between the Forestry Agency of the Ministry of Agriculture and Forestry and the National Park Division of the Ministry of Welfare to see whether the area should be designated as a national park. It would be a tragedy if the island's beauty were not perpetuated for future generations, and the International Union for the Protection of Nature has offered all possible help to its member, the National Parks Association of Japan, which in its turn is supporting the National Park Division's project (*Bull. Inter. Union Protect. Nature*, **4**, Nos. 5 and 6; December 1955).

WEATHER AND THE LAND

DURING the early years of his period of office the late Sir Nelson Johnson, director of the meteorological Office during 1938–53, realized that much greater assistance could and should be given by the Office to the economic life of Great Britain. One of his major decisions in this respect was the establishment in 1947 of the Agricultural Meteorological Section of the Climatology Branch, the Section becoming in 1948 the Agricultural Branch of the Office under the assistant director for climatology. Since then the Branch has developed its activities very widely. Besides the Branch office at the headquarters of the Meteorological Office, there are now meteorological advisers at the offices in Bristol and Cambridge of the National Advisory Service for Agriculture, and a meteorologist has recently been posted to the Meteorological Office, Edinburgh, for similar duties in Scotland.

A pamphlet written by the staff of the Branch* explains to the farmer the 'why and how' of his meteorological problems, how meteorologists can help to solve the problems, and how best to use the forecasts prepared at the Central Forecast Office and broadcast by the B.B.C.

The first chapter describes the general climate of the British Isles with special reference to plant growth, and the second gives the local variations in climate associated with altitude, aspect, and the nature of the soil and its covering. The third chapter explains the meteorological aspects of methods available for using solar radiation more efficiently by means of glasshouses and cloches, and methods such as shelterbelts and irrigation, of mitigating unfavourable meteorological effects. After this is a chapter describing the structure of depressions and the use of cloud forms and other portents of weather in interpreting the broadcast forecasts and applying them to local conditions. Finally, the fifth chapter gives the times of and areas used in the broadcast forecasts, lists the local meteorological offices from which forecasts can be obtained by telephone and the various special forecast services such as spell warnings which are available, defines terms used in weather forecasts, and states how the farmer can obtain advice (from headquarters, or from the meteorological offices attached to the National Advisory Service or to the Edinburgh Meteorological Office) on making the best use of his land.

The pamphlet gives a general compendium of meteorological knowledge as applied to agriculture in all its aspects and is of very great value to all agriculturists, while the parts on the use of the broadcast forecasts would be of much value to those whose business or pleasure is affected by the weather. Chapter 4 could well be used in schools for teaching the use of weather forecasts.

EMPLOYMENT STATISTICS FOR RECENT BRITISH GRADUATES

A RECENT broadsheet on "Graduates' Jobs", issued by Political and Economic Planning (No. 387), summarizes the results of an inquiry into the careers of 3,961 men who graduated in Great Britain in 1950. Returns were received from some 30 per cent of these, and it is unlikely that there is any main source of bias in the sample; more than half graduated in arts, more than a quarter in science, and less than one-fifth in technology. Many were older than the normal run of graduates, and most had seen war service or had done national service before going to a university. More than half had married by October 1954, and 20 per cent had married in the year they graduated or earlier.

Much the largest entries were into industry and teaching (both 23·4 per cent), mathematics and science teaching claiming 6·7 per cent, while 33 per cent of arts graduates became teachers as compared with 19·9 per cent of science graduates. The Civil Service took 8·6 per cent, 5·5 per cent (or 15·7 per cent of the science graduates and 3·9 per cent of those in technology) going into the Scientific Civil Service; 7·5 per cent went into commerce, 4·2 per cent into the universities, 4·1 per cent took up law, and 3·6 per cent went into local government service, including 8·3 per cent of the technologists. Of the technologists, 45·4 per cent went into manufacturing industry, 8·8 per cent into building, contracting and civil engineering, 6·5 per cent became consultant engineers and 6·1 per cent entered public utilities.

Industry claimed the highest proportion (23·7 per cent) of first-class honours graduates as well as second-class honours men (20·8 per cent) and 26·4 per cent of others, but over the past four years lost about 10 per cent of its entrants; the Scientific Civil Service claimed 11·0 per cent of first-class honours men and 5·5 per cent of those with second-class honours. Since 1950 it has lost 7 per cent of its intake. The universities, however, which claimed 17·8 per cent of first-class honours men, increased their share of graduates by nearly 4 per cent, whereas school teaching, which by contrast only attracted 2·8 per cent of first-class honours men in mathematics and science, 4·6 per cent of second-class honours men and 10·3 per cent of others (the corresponding figures for arts men being 6·5, 20·6 and 15·2) lost 7 per cent of its original entrants.

Commerce lost 25 per cent of the graduates who started in it; but in general there was a high degree of stability in occupation. Figures for the research associations, which took 2·9 per cent of the science graduates (as compared with 6·0 per cent for the universities) or 1·4 per cent of first-class and 1·7 per cent of second-class honours men, do not suggest that they absorb as yet any considerable proportion of the country's scientific man-power, but rather that their influence may be out of proportion to the numbers, like that of the universities, owing to the high quality.

ENGINEERING RESEARCH IN THE IMPERIAL COLLEGE, LONDON

THE report on research work in the City and Guilds College, 1952–55*, which represents engineering within the Imperial College of Science and Technology, London, where the number of engineering students now exceeds a thousand, appears appropriately when the expansion of the College is being widely discussed in relation to the need for engineers in Britain. Intended for the non-specialist and arranged in six sections, the report gives a readable and illustrated account of the many-sided contribution to national welfare and industrial advance which is already coming from the Departments of Aeronautics, Chemical, Civil, Electrical and Mechanical Engineering and Mathematics. In supersonics, while much effort has gone to the design of the new supersonic wind tunnel for the Roderic Hill Building, some theoretical work has been done on the pressures and forces acting on aircraft fuselages as they move through the air at supersonic speeds; detailed measurements are being made in a 5 ft. × 1 ft. wind tunnel on a jet ejected normal to a stream to determine how and why the jet turns along wind. General methods of analysis of aircraft structures have been developed, including the effects of non-linear elastic behaviour of materials and initial strains which arise with non-uniform heating of a structure. A systematic programme of tests over the past two years on riveted and redux-bonded joints indicates that the glued joints have better fatigue properties than their riveted equivalents, and that alloys of high static strength currently used in aircraft structures may be inferior under repeated loadings, particularly in regions of high-stress concentrations, such as joints, to the lower-strength alloys.

In chemical engineering, in connexion with the design of plant for purifying and liquefying natural gas on a large scale, the physical properties of the gas mixtures present are being further investigated, and an experimental plant has been erected for studying the distillation of liquid air. Problems of mass-transfer in solid–gas, solid–liquid, gas–liquid, and liquid–liquid systems, the drying characteristics of solids, the sedimentation of concentrated suspensions of particles in a liquid, fluidization of particles by means of an upward current of liquid, and transport by means of a gas or liquid are also being investigated, and an apparatus has been set up for studying both the sublimation of pure solids and the technical process of freeze-drying. The growth of an organic crystal from the melt has been investigated by a method in which the growth of individual faces is measured directly with a travelling microscope. The compressibilities of mixtures of steam and carbon dioxide have been measured up to 100 atmospheres and 650° C. In the high-speed fluid kinetics laboratory, the high-pressure supersonic flow through nozzles and the design of such nozzles for hot and cold gases are being studied, as well as the formation and disintegration of jets and sheets and the design of nozzles for atomization. Methods for concentrating low-grade iron ores have been examined, and an experimental technique has been designed for subjecting typical blast-furnace charges to the conditions they would encounter in descending the furnace. Other researches have been concerned with the basic chemical physics of gases and vapours, the melting of crystals containing organic molecules, mechanical wear and lubrication, the abrasion of copper and iron surfaces, flame spectroscopy and the accurate and detailed analysis of the peroxides, aldehydes, ketones, olefins and other intermediate products in the oxidation of hydrocarbons; and a fruitful study has been made of engine crank-case explosions.

In civil engineering, in connexion with the design of a large arch dam to be constructed at Dokan, Iraq, on a tributary of the Tigris, the elastic equations governing the stress distribution have for the first time been solved numerically, and the work assisted and confirmed by experimental methods using a material which has only recently become available. Work on thin-walled rectangular box girders conducted for the British Shipbuilding Research Association confirmed that introduction of expansion joints is a practice to be avoided. The Department has also fostered the application of simplified models to the analysis of building frames. Much work has been done on the fundamental strength and deformation characteristics of both reinforced and pre-stressed concrete framework members. Experiments on curved channels have yielded far-reaching results, and definite progress has been made in studying the movement of sediment along a river bed. Of particular interest are the work on the action of wind on a water surface, bearing directly on the North Sea floods of 1953, and the construction in the laboratory of a model of the Lynmouth valley with which a relation was established between the quantities of water flowing through the model and the corresponding water-levels. The resulting estimate of the flood was used by the engineer advising on the reconstruction of the damaged parts of Lynmouth. Further investigation of spillways, the fundamental and practical aspects of the shear strength of soils, the stability of earth dams and of clay slopes in railway, road and canal cuttings, the settlement of buildings, the sedimentation of water or sewage, the filtration of water through sand, and a continuing physical, chemical and biological study of new impounding reservoirs are other subjects in which the investigations of the Department directly impinge on public health or safety.

---

* Imperial College of Science and Technology (University of London). Report on research work in the City and Guilds College, 1952–55. Pp. ii+61. (London: Imperial College of Science and Technology, 1955.)

In the Department of Electrical Engineering, studies have been made of the effect of eddy currents in unlaminated materials in electrical machines, of cross-magnetization on the characteristics of a cross-field generator and of saturation and armature reaction on the building-up curve of a d.c. exciter supplying the field-winding of an alternator. Studies in the Power Systems and Computer Laboratories of physical phenomena arising in the transmission and utilization of electrical energy have involved the development of special measuring equipment. Other work has concerned the improvement of methods available for carrying out the numerical calculations required in engineering design and research. Special efforts have been made to develop and extend the statistical methods of control design. The Department has also engaged in research on human perception, especially speech and hearing, as well as various circuit applications of transistors, the distortion of microwaves resulting from the presence of dielectric and conducting cylinders and the determination of the reflexion coefficient of a set of parallel plates similar in form to those used in constructing lens aerials. Work in the Ultrasonics Laboratory is concerned with the behaviour of solids, liquids and gases under the influence of ultrasonic waves of varying frequency. The application of the so-called corona effect of high voltage in dry air has also been studied.

Researches in heat transfer in the Department of Mechanical Engineering have been concerned with the utilization of low-grade heat, with marine condenser tubes, with thermal stresses in steam turbine rotors, and heat transfer to gas turbine blades, as well as with heat transfer from a rotating disk. Other investigations have been concerned with combustion in reciprocating engines, the vibration of propagating flames, combustion in gas turbines and the use of the gas turbine for chemical reactions such as the cracking of methane to acetylene. A theoretical study has been completed of the stresses in and flexibilities of curved pipes, and the axial compression of six expansion bellows of three different types has been examined experimentally by electrical resistance strain-gauge surveys. Some plane strain processes are being examined to determine the region over which plane strain conditions apply, and to establish means for obtaining basic stress–strain curves for metals at deformations much greater than those attainable in the standard tensile test. A programme of research in photoelasticity is concerned with the possible extension of the method to the examination of materials which have been plastically deformed, and under another programme the failure of materials under relatively few cycles of high stress-intensity is being examined with the view of obtaining fundamental knowledge on fatigue as well as design data. Besides the study of the troublesome vibration known as 'oil-whirl' and thin-film lubrication, a vibrational method is being developed for the fatigue testing of metals; and an apparatus has been built for vibrating cantilevers of various shapes in several modes of bending and torsion.

In the Department of Mathematics, a major investigation was concerned with the design of an arch dam, and others with the numerical solution for the flow of a viscous fluid past fixed obstacles, and the temperature distribution in two conductors sliding over one another and generating heat by friction over their area of contact.

SPIRAL PATTERNING OF SOLAR CORPUSCULAR PRECIPITATION

By E. R. HOPE
Defence Research Board of Canada, Ottawa

THE plots of radio blackout distribution in the North American and North Atlantic region, as published by V. Agy[1] and J. H. Meek[2], agree with the isochrons of the 'morning' maximum of magnetic disturbance in the Arctic region, as found by (anonymous) Soviet research[3,4]. Fig. 1 (from ref. 3) shows these isochrons (geographical loci of simultaneous occurrence), which may be explained by a diurnally rotating spiral of solar corpuscular precipitation. Fig. 2 reproduces Agy's Figs. 5 and 6 [1].

To interpret Agy's and Meek's local-time plots, which show peculiar southward lobes centred at about long. 90° W. (as in the right-hand side of Fig. 2), W. R. Piggott[5] tried plotting in G.M.T. the longitudes where the maximum rate of occurrence of blackout (storm-D ionization) is found. This plot, extending over the Atlantic-Canada sector only, showed an apparent east-to-west rotation-period of 48 hr., on which basis Piggott suggested that there must be two D-region activity centres, separated by 180° of longitude, and rotating around the pole once in two days. Agy[1] then tried changing his local-time plot (Fig. 2, right) to a G.M.T. plot. This eliminated the lobes and clearly displayed the apparent 180° rotation in 24 hr. (Fig. 2, left).

Table 1 shows the G.M.T. isochrons in Fig. 1 and Fig. 2 (left), with the longitudes where they cross the circle of latitude 60° N.

Allowing for the fact that Agy's plot is for the summer season only, while the Russian data are probably for the whole year, the agreement of isochrons 00–14 is excellent. The directions of these isochrons also correspond rather well, as may be judged by visual comparison.

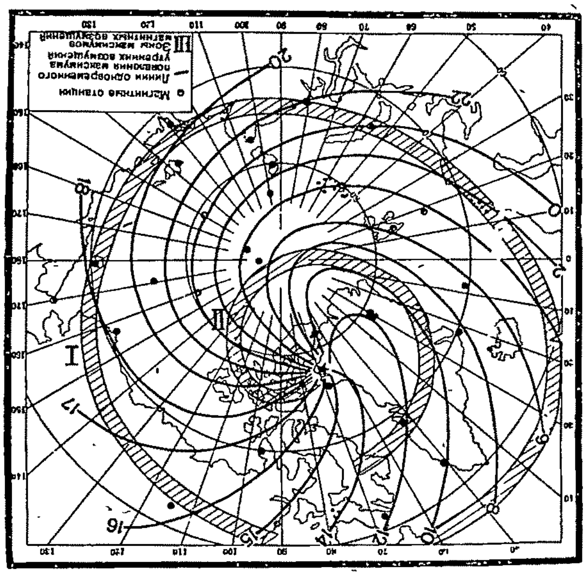

Fig. 1. Isochrons of morning maximum of magnetic disturbance (the figures attached to the isochrons represent world time). ●, Magnetic stations; —, isochrons of maximum of morning disturbance; I and II, maximum zones of magnetic disturbance. The figure, which is taken from ref. 3, is inverted to facilitate comparison with Fig. 2

We conclude that Agy's G.M.T. isochrons 00–14 are low-latitude continuations of the Soviet isochrons. (The disturbance-spiral, on magnetically disturbed days only, may extend its effects far southward; its passage appears to be detectable in the earth-currents at Tucson. See translator's comments to ref. 6.)

One is impressed by the complete independence of the work and data in the two cases. Soviet isochrons: diurnal maximum of magnetic disturbance (probably based on amplitude of magnetic variation); Agy's isochrons: maximum of fundamental Fourier harmonic of diurnal variation of *F*-layer blackout probability (*D*-layer or *E*-layer absorption).

A fact of capital interest is that west of isochron 14 the agreement abruptly disappears. Yet the northern parts of the isochrons (14, 16, 18) still agree, in both position and direction. Above 70° N., this is true even of isochrons 20, 22, 00. On Fig. 2 (left), a smoothly curving line may be drawn, beyond which the Soviet isochrons seem to disappear suddenly under a different set of north–south contours (cf. ref. 4, pp. 19, 23, "axis maximum" and its times). It will be interesting to pencil in, on the charts, the position of the great Arctic magneti anomaly[3], and to compare it with the sharp bend in Agy's isochrons.

Table 1

Isochron	Crosses 60° N. at longitude: (Agy, Fig. 2)	(U.S.S.R., Fig. 1)
G.M.T. 00	15 E.	10 E.
02	0	5 W.
04	20 W.	15
06	35	27
08	45	41
10	60	57
12	75	69
14	95	83
15	—	100
16	115	115
17	—	170 (extrapolated)
18	—	120 E. (extrapolated)
20	160 W.	60 E
22	167 W.	25 E.
00	175 W.	10 E.

Now the non-uniform rotation (Fig. 1) of th disturbance-spiral accounts precisely for Piggott' apparent 48-hr. period. Between isochrons 00 an 12 in the Atlantic sector, it will be seen that th spiral is rotating just half as fast as the sun.

Farther west, the accelerated rotation (Fig. 1) mus enfeeble the disturbance effect by spreading it over larger area. This would help the disappearance of th Soviet isochrons under what we suppose to be the independent contours in the Bering Sea area (ref. 4, p. 21

Whereas the G.M.T. plot shows actual momentar positions of the disturbance wave, the local-time plo only shows synchronic relationships along eac meridian separately. In Fig. 2 (right), the northwar progression of the local-time isochrons is due to th rotation of the disturbance-spiral, for along any give meridian the motion of the spiral is poleward. Th 'lobe' shape, a kind of artefact, is produced as follow In the eastern half of the lobe the sun is gaining o the spiral; if the observer moves from meridian t meridian at the sun's speed (as in this plot), he see the spiral in this region turning backward, west t east, and its arm moving south. The bottom of th lobe marks the point where the speeds of the sun an the spiral are about equal. After this, the spiral gain on the sun, and appears to move north along th meridian.

What the local-time plot provides is a graphica comparison of velocities. From the uniform orientation (toward 90° W.) of the contours in the lobe, an their uniform spacing, we see that different segment of the disturbance wave are rotating at differen velocities (that is, the spiral is progressively deformed and that the rotation-velocity of each segmen depends only, or mainly, on longitude.

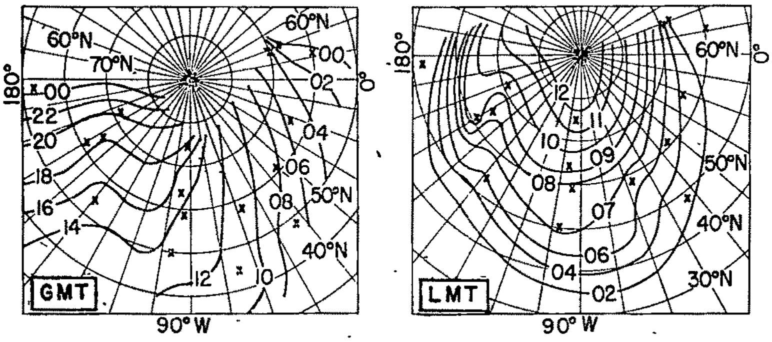

Fig. 2. Time of maximum percentage of time of blackout φ_i during summer (from Vaughan Agy, ref. 1)

I am grateful to Dr. Vaughan Agy for permissio to reproduce Fig. 2, and to the Canadian Defenc Research Board for authorizing publication of thi communication. [Oct. 22

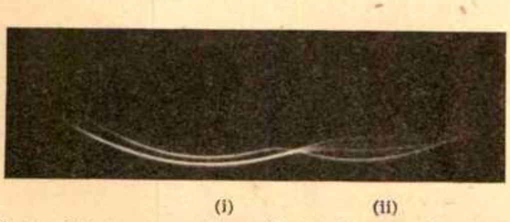
Immunological Methods in Plant Taxonomy

THE application of immunological analysis to plant taxonomy has been made practicable by the development of gel-diffusion methods, both by the Elek–Ouchterlony technique[1] and by the more recent immuno-electrophoretic technique of Grabar and Williams[2]. By these means the individual proteins in plant extracts may be differentiated and the extracts compared component by component with those from related species. We have applied a modification of these general methods to the investigation of the genus *Solanum*, with particular reference to the inter-relationships of certain Mexican species of potato, and the comparison of these with *S. tuberosum*, the domestic potato.

Thin slices of tuber of each species were soaked in sodium hydrosulphite (0·7 per cent solution) for 30 min., rinsed in distilled water and the sap expressed by crushing the slices, supported within folded strips of moist calico, through stainless steel rollers. Antisera were raised in rabbits to crude saps from *S. tuberosum* and *S. ehrenbergii* (a Mexican species), using a combination of Freund's adjuvant technique[3] with courses of intravenous injections. Agar containing veronal buffer (*p*H 8·5) was poured to a depth of 2 mm. on lantern slides in 'Perspex' frames; in the agar, holes were cut with a cork-borer to hold the tuber extracts to be compared, and a trough at a distance of 1 cm. to hold the antiserum. The reagents were allowed to diffuse towards one another and lines of precipitate formed, each line corresponding to an antigen–antibody system. Where lines from different extracts joined end to end they were assumed to belong to identical or cross-reacting proteins. In some cases a much improved separation of the lines was obtained by subjecting the antigen to a short (4-hr.) electrophoresis before adding the antiserum (Fig. 1).



(i) (ii)

Fig. 1. *S. tuberosum* reacting with homologous antiserum. (i) Without electrophoresis the antigen shows only two lines of precipitate; (ii) with electrophoresis, one of the lines has been split into three, and their relative positions changed

With both antisera, well-marked cross-reactions occurred between all the forty species examined; but by comparison of the 'line spectra' and by cross-absorptions of the antisera, it was possible to divide the species into well-defined groups.

By using *S. tuberosum* antiserum, the fourteen Mexican species were separated into three divisions (Fig. 2*a*) and then by the use of the antiserum against *S. ehrenbergii* two of these could be further subdivided, giving a total of five groups (Fig. 2*b*). Each group, with the exception of one, corresponded to a particular taxonomic series according to the classification proposed by Hawkes[4]; the one exception (Group 4) contained species from two series. The taxonomic series corresponding to the groups mentioned here are as follows: Group 1. Series *Morelliformia*. Group 2: Series *Pinnatisecta*. Group 3: Series *Cardiophylla*. Group 4: Series *Demissa*, and *Longipedicellata*; *S. tuberosum* and other South American species. Group 5: Series *Bulbocastana*.

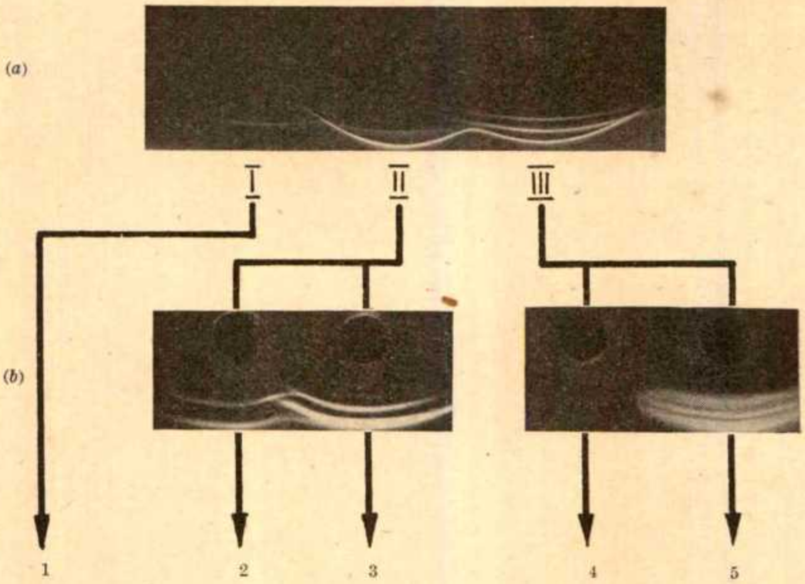


Fig. 2. (*a*) Separation of the species into three divisions with *S. tuberosum* antiserum. (*b*) The splitting of group II into two by means of unabsorbed *S. ehrenbergii* antiserum and of group III into two by means of the same antiserum absorbed with *S. tuberosum* extract

These results will be published in detail elsewhere. The work is being carried out mainly under a grant from the Nuffield Foundation.

Effects of Single and Fractionated Doses of X-Rays on Mouse Embryos

THAT embryonic tissues *in vitro* may be affected more drastically by fractionated, than by single, doses of X-rays was shown by Spear in 1932 [1]. Working with chick embryo fibroblasts, he demonstrated that the depression of activity of these cells is far greater with two 2½-min. exposures separated by 80 min. than with a single 5-min. exposure. In view of the possible significance of these findings for our understanding of the nature of embryonic damage resulting from X-irradiation, and in view of the general interest in the question of radiation hazards to the developing mammalian embryo, the present experiment was designed to determine whether there is a difference between the effects of single and fractionated doses of X-rays on developing mouse embryos *in vivo*.

Strain-101 female mice were mated to strain-*C3H* males and irradiated with X-rays (250 kVp., 15 m.amp., 3 mm. aluminium, half-value level 0·4 mm. copper, 80 r./min.) 9½ days after the appearance of copulation plugs. Irradiation was administered either as a single dose of 300 r. or as three 100 r. fractions at 30-min. intervals. Embryos were obtained by dissection three to six days after irradiation. The majority of dissections were made on coded animals. The criteria used were lumbo-sacral spina bifida and coloboma of the eye, two abnormalities which, following irradiation on day 9½, are produced with high frequency[2] and are easy to classify accurately by gross inspection. The lumbo-sacral region was scored for length of antero-posterior axis affected ; each eye was scored separately for extent of pigment defect.

The two criteria represent strikingly different developmental disturbances. The lumbo-sacral damage consists of a disorientation of the neural tube and somites, resulting in neural arch malformation ; the eye defect represents an altered differentiation of optic cup elements, resulting in the presence of retinal sensory cells in areas normally consisting of pigment epithelium (unpublished results).

The results of single and fractionated doses of X-rays are compared in Table 1. While the incidence of malformation is not affected by fractionation, the severity of embryonic defects is far greater in response to a fractionated dose than in response to a single dose. A striking parallel can be seen between the relative effects of these two methods of irradiation on the lumbo-sacral axis and on eye pigmentation.

It would be premature to speculate on the nature of the processes responsible for the differential effect of single and fractionated irradiation on development. However, from the point of view of developmental mechanics[3], any interpretation of the nature of embryonic damage in response to X-irradiation must consider the present results, namely, that in the two widely differing embryonic systems so far studied, fractionation is more effective than a single dose, and the degree of increase in effectiveness is similar in the two systems. From the point of view of radiological practice[4], the demonstration that short-interval fractionation can increase the radiation hazard to developing embryos *in vivo* adds yet another factor calling for caution.

Table 1. COMPARISON OF THE EFFECTS OF SINGLE AND FRACTIONATED DOSES OF X-RAYS ON DEVELOPING MOUSE EMBRYOS

	Lumbo-sacral region				Eye pigment formation			
	300 r. single dose		300 r. fractionated dose		300 r. single dose		300 r. fractionated dose	
		(per cent)		(per cent)		(per cent)		(per cent)
Normal	12	11·4	12	15·0	33	15·7	22	13·8
Mildly abnormal*	90	85·7	17	21·3	158	75·2	29	18·1
Severely abnormal†	3	2·9	51	63·8	19	9·0	109	68·1
Total	105		80		210		160	

* Includes all embryos in which the extent of abnormality (measured in mm. of lumbo-sacral axis and percentage of eye surface) is less than half that found in the most abnormal embryo.

† Includes all embryos in which the extent of abnormality is at least half that found in the most abnormal embryo.

This work was carried out under contract *W*-7405-*eng*-26 for the Atomic Energy Commission.

A Requirement for Catalase in Tyrosine Metabolism : the Oxidation of *p*-Hydroxyphenylpyruvic Acid to Homogentisic Acid

IN this communication evidence is presented that catalase is required in one of the steps of tyrosine metabolism, namely, the conversion of *p*-hydroxyphenylpyruvic acid to homogentisic acid. This oxidation requires two protein fractions which have been separated and partially purified from dog liver by treatment with organic solvents followed by fractionation with ammonium sulphate[1]. Fraction *A* is precipitated by 0·40–0·55 saturated ammonium sulphate ; fraction *B* by 0·60–0·75 saturated ammonium sulphate.

In studies to establish the function of the two protein components, it was observed that fraction *A* contained appreciable amounts of catalase and that the activity of this fraction was proportional to its catalase content. Further experiments showed that fraction *A* could be replaced by purified catalase obtained from beef or rat liver (Table 1). The product formed from *p*-hydroxyphenylpyruvic acid with fractions *A* plus *B* or with catalase plus fraction *B* was identified as homogentisic acid by chemical analysis and by paper chromatography with methods previously described[2]. Catalase appears to be specifically required in this oxidation, and could not be replaced by ferritin, hæmoglobin or cytochrome *c*.

Various amounts of catalase were added to constant amounts of fraction *B* (sufficient in the presence of excess catalase to oxidize 5 µmoles of substrate in one hour) to study the effect of catalase on the reaction. When catalase was present in limiting amounts, the rate of reaction, as measured by oxygen uptake, was proportional to the amount of catalase added. 5γ of catalase was sufficient to give about one-half the maximal rate and 1γ produced significant activity. However, at least 30γ of catalase was required to give the maximal reaction-rate. The low activity observed when fraction *B* was tested alone

Table 1. EFFECT OF VARIOUS CATALASE PREPARATIONS ON THE OXIDATION OF *p*-HYDROXYPHENYLPYRUVIC ACID TO HOMOGENTISIC ACID

Incubation conditions: The main compartment of the Warburg vessels contained 1·0 ml. of 0·2 *M* phosphate buffer, *p*H 6·5, 20 μmoles of neutralized glutathione, 100γ of 2,6-dichlorophenolindophenol, the enzyme preparations described below and water to make a total volume of 2·0 ml. The side-arm held 5 μmoles of *p*-hydroxyphenylpyruvic acid in 0·5 ml. of 0·2 *M* phosphate buffer, *p*H 6·5, or buffer alone in the control flasks. The centre well contained 0·2 ml. of 20 per cent potassium hydroxide. Incubation was at 37° C. for 1 hr. with air as the gas phase and a shaking rate of 180 oscillations per min

Catalase preparation Source	(Per cent purity)	γ of catalase*	Fraction *B* (900γ/flask)	Substrate oxidized in 1 hr (μmoles)
Rat liver†	86	28·8	–	0
Beef liver‡	20	432·0	–	0
Beef liver	20	27·0	+	4·8
Rat liver	86	28·8	+	4·9
Rat liver	86	9·6	+	3·9
Rat liver	86	4·8	+	2·5
Rat liver	62	5·0	+	2·5
None	—	—	+	0·7

* Based upon the activity of pure rat-liver catalase; 1 unit of activity is defined as the amount necessary to decompose 63·2 per cent of the remaining peroxide in one sec. 1 unit of activity is equivalent to 5·85γ of pure rat liver catalase. We are indebted to Drs. R. Greenfield and V. Price for assay of these preparations.

† The rat liver catalase preparations were kindly supplied by Dr. R. Greenfield. The principal contaminant in these preparations, a protein with S_{20}, W of 6·3–6·5 (ref. 8), was eliminated as the active component by comparing the activity of catalase preparations of different purity.

‡ Crystalline beef liver catalase from Worthington Biochemical Corporation.

(Table 1) was probably due to a small amount of catalase still present, since it is very difficult to obtain fraction *B* completely free of catalase.

When large amounts of catalase (432γ) were incubated with all additions except fraction *B*, no oxidation of *p*-hydroxyphenylpyruvic acid occurred (Table 1). Even in the presence of enzymatically generated peroxide, catalase did not catalyse the oxidation of *p*-hydroxyphenylpyruvic acid to homogentisic acid.

The exact mechanism by which catalase participates in this reaction has not been established. If hydrogen peroxide is involved, it would have to arise from the oxidation of *p*-hydroxyphenylpyruvic acid, since there is no oxygen uptake in the absence of the substrate.

It is well known that catalase can function as a peroxidase with various compounds[3], such as alcohols[4,5], nitrite[6], phenols and amines[7], and it has long been suspected that under physiological conditions catalase may not only decompose hydrogen peroxide but also participate in oxidative reactions. The present studies on the oxidation of *p*-hydroxyphenylpyruvic acid to homogentisic acid have demonstrated, for the first time, a requirement for catalase in the oxidation of a normally occurring substrate. It is possible that catalase, in association with other oxidases, may participate in other reactions of this type.

Effect of Blocking the Reticulo-endothelial System on the Storage of Vitamin A Ester and Alcohol in the Liver of the Rat

VITAMIN A is absorbed through the lymphatic system mostly in the esterified form[1] and is stored in the liver predominantly as ester with small amounts of the free form. Its absorption via the lymphatic route raises the question of the reticulo-endothelial system being associated with its storage mechanism in the liver. Experiments, carried out in this laboratory, consisting of intraperitoneal injection of indian ink followed by oral administration of oily solutions of vitamin A, show a marked interference in the deposition of the esterified form of the vitamin in rat liver, the free form remaining unaffected.

Male rats of this Institute were raised on a diet low in vitamin A composed of white rice, casein, yeast, groundnut oil and minerals, and were used when they weighed 75–100 gm. One group of rats was kept on the basal diet alone to serve as negative control; each of a second group of six rats was given one intraperitoneal injection of 1 ml. of normal saline daily for seven days and a single oral dose of 3,000 μgm. of vitamin A in 0·2 ml. of groundnut oil on the last day of the injections, and a third group of six rats received treatment similar to the second group, except that 1 ml. of a 20 per cent suspension of indian ink ('Reeves Fixed Indian Ink') in normal saline, instead of normal saline alone, was used. All rats were fasted for 24 hr. after the dose and bled to death by drawing as much blood as possible from the heart while under light ether anæsthesia. Plasma was extracted according to the method of Kimble[2] and the liver with anhydrous sodium sulphate and peroxide-free diethyl ether[3]. The two forms of vitamin A were separated and determined as described by Ganguly *et al.*[4], excepting that a Klett-Summerson photoelectric colorimeter, with a red filter, standardized against standard vitamin A, was used for the determination of the Carr–Price reaction.

The results, as presented in Table 1, show a markedly lower concentration of the ester form of vitamin A in the liver and a markedly higher value of the same form in the blood of rats treated with indian ink, as compared to those treated with saline, demonstrating that blocking of Kupffer cells interferes with the storage of vitamin A ester in the liver of the rat; this confirms the earlier findings of Kagan *et al.*[5] in the guinea pig. In contradistinction to the vitamin A ester values, the vitamin A alcohol values are almost unaffected in the liver, probably indicating different mechanisms of storage of the two forms of vitamin A in the liver and lending

Table 1. EFFECT OF INTRAPERITONEAL INJECTION OF INDIAN INK ON THE VITAMIN A ESTER AND ALCOHOL VALUES IN BLOOD AND LIVER OF RATS

No. of rats	Treatment	Blood (μgm./ml. plasma)		Liver (μgm./organ)	
		Vitamin A ester	Vitamin A alcohol	Vitamin A ester	Vitamin A alcohol
6	Negative control	*	*	10·2 (8–12)	1·4 (1–1·8)
6	Saline + 3,000 μgm. vitamin A	1·9 (1·6–2·2)	1·2 (0·8–2·0)	2,238·3 (1,980–2,450)	56·0 (45–65)
6	Indian ink + 3,000 μgm. vitamin A	5·1 (3·5–8)	1·9 (1–2·5)	1,168·8 (900–1,322)	54·3 (47–61)

* Too low for determination.

support to such a concept put forward by Krinsky and Ganguly[6]. In separate preliminary experiments, in which liver homogenates of normal stock rats were dialysed against a series of buffers ranging from pH 7·0 to pH 4·0, we have found that the two forms of vitamin A are precipitated at different pH values. This observation also lends further support to this concept. Further work is in progress and a detailed report will be published elsewhere.

This investigation was aided by a research grant from the Indian Council of Medical Research and by the Rockefeller Foundation.

Differences between the Electrical Charge carried by Normal and Homologous Tumour Cells

Differences between the behaviour of normal fibroblasts and sarcoma cells have been observed in tissue culture by Abercrombie and Heaysman[1]. Normal fibroblasts affect each other's movements by contact inhibition, whereas sarcoma cells do not show inhibition either with respect to each other or to normal fibroblasts. Time-lapse colour films taken with the interference microscope (shown at the Bristol meeting (1955) of the British Association by E. J. Ambrose and M. Abercrombie) have shown that this difference in behaviour is due to differences in the mechanism of contact formation in the two cases, being dependent upon a loss of adhesiveness of the cell surface of the tumour cells. This reduction in the adhesiveness of the tumour cell suggests that the electrical properties of the surface may have altered during the malignant transformation. These properties may be investigated by electrophoretic measurements of cellular mobility. For example, studies of bacteria during growth, in the presence of bacteriostatic agents, have revealed marked changes in the nature of the cell surface, changes which are passed on to the progeny during subsequent growth, either in the presence or the absence of the drug. Thus the growth of *Aerobacter aerogenes* in the presence of proflavine[2] or crystal violet[3] gives rise to new populations of cells, which, although biologically indistinguishable from the original strain, have a distinctive electrometric behaviour.

The electrophoretic technique used for this work[4] has now been extended to a study of the surface behaviour of normal and homologous tumour cells. The tissue cells, separated by the perfusion method of Anderson[5], were washed twice on a centrifuge run at low-speed with $M/30$ phosphate buffer solution (pH 6·8, ionic strength 0·13) and finally suspended in the same solution. Tumour cells and red blood cells were washed in a similar way. All determinations of mobility were carried out in the buffer solution. Samples of hamster kidney tumours[6] induced by stilbœstrol were obtained in a highly distinct and compact form. Samples of rat liver tumours induced by butter yellow were also examined. Red blood cells from the same tissues were used as internal controls. This method eliminated any possibility of alterations due to changes in the serum proteins of the tissues, which could become absorbed on the cell surface. Red blood cells for a given mammal were found, in fact, to have a mobility which was independent of their source. Preliminary studies of ascites tumour cells (mouse Ehrlich carcinoma) showed that the mobility of the intact cells was independent of size of cell and tumour age.

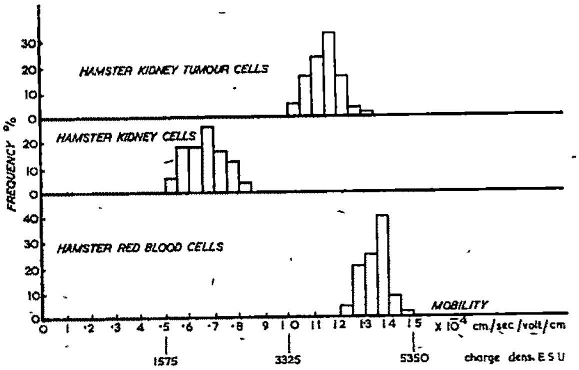

Fig. 1. Electrophoretic mobilities of intact cells. Histograms showing the mobility of red blood cells, normal and tumour kidney cells of the hamster. Each cell type shows a Gaussian distribution about the mean

Typical histograms for the normal and homologous tumour kidney cells are shown in Fig. 1. The average charge density of the tumour cells is almost twice that observed with the normal cells from which they have been derived. A similar increase in mobility was observed with the liver tumours. In this case, the tumour values were not so homogeneous, because these tumours are more diffuse than kidney tumours and suffer from some contamination with normal cells. The increase in the mobility of the tumour cells indicates either a change in the number of charged groups attached to the high-molecular weight material, for example, the carboxyl-rich chains of the protein, or a change in the ability to absorb positive ions. That the latter may in fact be the case is suggested by observations of de Long, Coman and Zeidman[7], that tumour tissues show a decreased calcium content in comparison with normal tissues.

Changes in the nature of the cell surface may possibly provide a new approach to the chemotherapy of cancer and enable a preferential attack to be made on the malignant cell.

We thank Prof. A. Haddow for his interest in this work, and we are indebted to Prof. J. A. V. Butler for valuable help and suggestions. We also wish to thank Dr. E. Horning, who supplied the samples of hamster kidney tumours, and Dr. D. Darcy, who supplied the rat liver tumours. One of us (J. H. B. L.) acknowledges continued financial support from the British Empire Cancer Campaign. Influence of a Magnetic Field upon the Leucocytes of the Mouse

THIS communication contains the results of one part of the research programme aimed at studying the effect of magnetic fields on living organisms and tissues. Female *C3H* strain mice from the Roscoe B. Jackson Memorial Laboratory were kept for 4–5 weeks in magnetic fields of 4,200 gauss strength, produced by 'Alnico' permanent magnets. The animals were placed in individual cages 3·5 in. inner diameter and 1·40 in. height. The magnetic field-strength was in the centre of the cages 4,400 gauss, decreasing to 4,000 gauss toward the periphery of the cage, as measured with a Dyne-Empire Model *D*-79 gauss meter. Control animals were kept in identical cages, wherein the pole-pieces of the magnets were simulated with 1-in. thick brass disks to provide identical conditions with respect to temperature, illumination and cosmic radiation[1]. The food of the animals consisted of standard Rockland mouse diet in pellet form. Blood samples taken from the tail at intervals of 7–14 days were investigated with respect to white blood count, red blood count and differential count.

The first experimental series was performed on mice forty weeks old during the spring of 1955. In this series nine mice were kept in magnetic fields for five weeks and in standard plastic cages, 4–5 animals in each cage, for an additional eight weeks after removal from the field. In this series no control animals were used.

The second similar experimental series was performed during late summer and autumn of 1955 on mice nine weeks old. In this series, nine mice were kept for four weeks in the magnetic fields and remained during the fifth week in their individual cages, however, removed from the field. Thereafter they were transferred to standard plastic cages, 3–4 animals in each cage for an additional thirteen weeks. In this series four control mice were kept for five weeks in individual cages and thereafter transferred to a plastic standard cage. The blood samples were taken from all animals, treated and controls alike, always on the same dates.

(*a*) In both series a significant decrease in the number of segmented cells is observable within the first two weeks while the animals were kept in the magnetic fields. This change cannot be attributed to the confinement to small cages, because the controls confined to identical cages seemed rather to indicate an increase in the number of segmented cells. The average decrease is 28·7 ± 6·7 per cent for the first and 47·9 ± 8·6 per cent for the second series (errors mean standard errors); indicating that the effect is significant on the level: $P < 0{\cdot}001$. Table 1 illustrates for the animals of the second series the individual differences between starting value (base line) and lowest value reached within the first fourteen days, as a percentage of the starting value.

(*b*) After removal from the magnetic field the number of segmented leucocytes increases and reaches a maximum a few weeks after removal from the field. The mean increase is for the first series 135 ± 30 per cent and 226 ± 65 per cent for the second, expressed in per cent of the minimum. These values indicate that the effect is significant on the probability level: $P < 0{\cdot}001$. That this maximum cannot be considered as a result of the transfer of the animals from the small cages to standard cages is proved by two circumstances: (1) no such increase was observed with the controls; (2) the majority of the mice manifested the maximum in the number of segmented cells one week after removal from the field; that is, at a time when they were still in small individual cages.

(*c*) The increase is followed by a decrease below the base-line value: the mean decrease being 59·4 ± 7·0 per cent in the first and 33·2 ± 8·2 per cent in the second series; the values given in per cent of the previous maximum. This effect is significant on the probability level: $P < 0{\cdot}001$.

(*d*) In the second series, where the observations were continued over a period of 124 days, the last counts again gave base-line values.

In the number of the lymphocytes a significant increase was observed in both experimental series after the animals were removed from the magnetic fields. The mean increases between the value shown at the time of removal and the following maximum, expressed as a percentage of the lower value, were: 270 ± 56 per cent in the first and 28·1 ± 6·5 per cent in the second series respectively. The effect can thus be considered significant on the probability level: $P < 0{\cdot}001$. The control animals did not show any significant change in the number of their lymphocytes. The count taken on the 124th day in the second series seems to indicate an increase of 38·6 ± 16·6 per cent above the base-line value; however, the probability-level of this effect is only $P = 0{\cdot}02$. No significant change was observed in the red blood count in either of the two experiments.

The observations on histological changes of organs of the mice kept in a magnetic field will be published elsewhere.

Effect of Cortisone on the Serum Gamma-Globulin

Nicol and Snell[1] showed that cortisone depresses the phagocytic activity of the reticulo-endothelial system during the first two weeks of treatment, and that if the cortisone injections are continued the reticulo-endothelial system apparently recovers during the third and fourth weeks. Nicol and Bilbey[2] reported that cortisone also produces changes in the blood. They showed that when 10 mgm. of cortisone is given daily intramuscularly for one or two weeks, the total leucocyte count falls, due to reduction in the number of lymphocytes and polymorphs; but if the cortisone is continued for three or four weeks the total leucocyte count returns to normal, due to increase in the number of polymorphs, although the lymphocyte count remains low.

The present communication deals with the effect of cortisone on the antibody-level in the serum, the serum γ-globulin-level being taken as the measure of the antibody-level, since most antibodies are found in association with the γ-globulin fraction of the serum protein. In this investigation the γ-globulin-level was estimated by first separating the γ-globulin fraction by paper electrophoresis, then treating the electrophoretic paper with dyes and estimating the optical density of the protein dye complex by means of a photoelectric cell. In this manner the percentage of γ-globulin in relation to the total protein in the serum could be assessed.

Twelve male guinea pigs, aged about one year, were used for this investigation. Blood samples were first taken from each animal by heart puncture and the γ-globulin-level of normal serum estimated as described above. Each animal then received a daily dose of 10 mgm. of cortisone intramuscularly for five weeks, the blood samples were taken at weekly intervals and the γ-globulin-level of the serum estimated. More than forty estimations of this kind were made during the five weeks of cortisone treatment.

In all the animals the γ-globulin level became markedly reduced during the first two weeks of the cortisone injections and thereafter remained at a low level. In two of the animals, however, it increased slightly during the fourth and fifth weeks. These findings are in agreement with Bjørneboe, Fischel and Stoerk[3], who showed that cortisone inhibits the production of antibodies during active immunization and also after immunization is well established. They are also in line with the other blood changes recorded by Nicol and Bilbey[2]. Further, they emphasize the profound depression of the body defences produced by cortisone, and the great necessity to protect patients from intercurrent infection especially during the early stages of cortisone therapy.

Action of Ribonuclease on the Multiplication of the Influenza Virus

Recent work of Ada and Perry[1] on the nucleic acid composition of influenza virus has shown that the infectious particles lack deoxyribonucleic acid, and that they contain about 0·8 per cent of ribonucleic acid. The degree of infectiveness is, in fact, a function of the ribonucleic acid content; the 'incomplete' form of the virus is characterized by a low infectivity/hæmagglutination ratio, and its ribonucleic acid content is lower than that of the standard form[2].

Indirect evidence for the importance of nucleic acid in the virus constitution is also given by the inactivation curve of virus infectivity by ultra-violet light; maximum effect is obtained[3] at a wave-length of 2652 A.

In the case of the tobacco mosaic virus, Casterman and Jeener[4] have observed a marked inhibition of synthesis of the virus by ribonuclease. The present work was undertaken with the hope of further defining the role of ribonucleic acid in virus growth, by studying the inhibitory action of ribonuclease on the multiplication of influenza virus.

Virus of strain *PR*8 was cultivated in the allantoic cavity of the embryonated egg, or in test-tubes on a fragment of chorioallantoic membrane suspended in 1 ml. of diluted Hanks solution (method of Tamm *et al.*[5]). The hæmagglutinating power was assayed with chicken red-blood cells, by serial dilution of the culture medium. The infectivity was estimated by the method of Reed and Muench[6], after inoculation of embryonated eggs.

The enzymatic activity of the ribonuclease (G.B.I. or Armour) in the culture medium corresponded to concentrations of 0·1–0·7 mgm./ml. Tubes containing oxidized (inactive) ribonuclease served as controls. The following results have been obtained.

(1) The presence of ribonuclease in the culture medium inhibits completely the synthesis of the influenza virus cultivated on fragments of chorioallantoic membranes. In the controls, the hæmagglutinating titre rises regularly during incubation.

(2) Ribonuclease added to the culture medium at various times after introduction of the virus inhibits

Table 1. TREATMENT BY RIBONUCLEASE AT VARIOUS TIMES AFTER INFECTION BY THE VIRUS

Time between virus and ribonuclease injections	Hæmagglutinating titres, after incubation for 24 hr. at 37° C. Controls	Treated
(*a*) *In vivo*		
− 30 min. (before)	$10^{3\cdot 1}$	$10^{0\cdot 6\pm 0\cdot 3}$
+ 3 min. (after)	$10^{3\cdot 0}$	$10^{0\cdot 6\pm 0\cdot 3}$
+ 60 min.	$10^{3\cdot 0}$	$10^{1\cdot 6\pm 0\cdot 5}$
+ 2 hr.	$10^{3\cdot 4}$	$10^{3\cdot 4}$
+ 6 hr.	$10^{3\cdot 2}$	$10^{3\cdot 3\pm 0\cdot 1}$
(*b*) *In vitro*		
0 hr.	$10^{3\cdot 0}$	$10^{0\cdot 6\pm 0\cdot 3}$
+ 1 hr.	$10^{3\cdot 6}$	$10^{1\cdot 6\pm 0\cdot 2}$
+ 2 hr.	$10^{3\cdot 3}$	$10^{2\cdot 7\pm 0\cdot 3}$
+ 4 hr.	$10^{3\cdot 7}$	$10^{2\cdot 5\pm 0\cdot 3}$
+ 6 hr.	$10^{2\cdot 8}$	$10^{2\cdot 6\pm 0\cdot 2}$

virus multiplication, but only within the first two hours after infection. The same experiment with the chick embryo gives similar results: the enzyme (0·1 ml. of an 8 mgm./ml. solution) was injected into the allantoic cavity at various times after the virus had been injected (Table 1).

(3) Fragments of chorioallantoic membrane treated during 1 hr. with ribonuclease, and then well washed in saline at 37° C., support the growth of hæmagglutinating particles, but there is a lag-time of about ten hours.

(4) A good correlation has been observed between infectivity and hæmagglutinating power: the hæmagglutination titre can thus be considered as proportional to the number of active virus particles.

The following hypotheses may be considered in order to explain the facts.

(*a*) Ribonuclease acts directly on the ribonucleic acid of the particles, before they enter the cells of the membrane. This hypothesis can be discarded at once, since a suspension of influenza virus treated with ribonuclease, and then purified by adsorption on and elution from red blood cells, keeps its agglutinating and infective powers intact.

(*b*) Ribonuclease prevents the adsorption on, or penetration of the virus into, the host cells. This explanation is unlikely; the multiplication of the virus is not affected when the chorioallantoic membrane is infected with the virus in the presence of ribonuclease and washed after 1 hr. Adsorption and penetration of virulent particles are thus not prevented by the enzyme.

(*c*) Ribonuclease alters the metabolism of the host cell and thus prevents the synthesis of the virus.

In order to test this last hypothesis, the following experiment has been carried out: phenylalanine-^{14}C was added to fragments of the membrane previously treated with oxidized or reduced ribonuclease; no difference was found in the specific radioactivity of the proteins. The turnover-rate of the proteins is thus not affected by the ribonuclease The incorporation of adenine-^{14}C, on the contrary, is much reduced in membranes treated with the active enzyme. Further experiments are needed in order to decide whether this inhibition is correlated with a decrease in ribonucleic acid turnover. However, this inhibition of adenine incorporation into membranes treated with ribonuclease cannot entirely explain the inhibitory action of the enzyme on virus growth, since such membranes are still capable of supporting virus synthesis.

In conclusion, ribonuclease, in the reduced state only, prevents synthesis of the influenza virus provided that it acts during the first two hours after infection, that is, during the beginning of the lag period. It does not act directly on the ribonucleic acid of the infectious particles, and it does not prevent their adsorption on and penetration into the host cells.

A possible explanation of our findings is that the influenza virus separates into ribonucleic acid and protein when it penetrates into the cell, as has already been suggested for other viruses; in this free state, the virus ribonucleic acid might be sensitive to ribonuclease. If so, ribonucleic acid has essentially the same function in the influenza particle as deoxyribonucleic acid in the bacteriophages, and it might thus be responsible for genetic continuity.

Incorporation of Adenine and Uracil into Ribonucleic Acid during Enzyme Induction in Resting Yeast

Spiegelman *et al.*[1], Pardee[2] and Creaser[3] have shown that purine or pyrimidine analogues inhibit induced enzyme formation in various micro-organisms. This strongly suggests that synthesis of nucleic acid is necessary for the formation of adaptive enzymes. Gale and Folkes[4] have shown that incorporation of uracil into ribonucleic acid is increased during induced formation of galactosidase in disrupted *Staphylococcus*.

Similar results have been obtained in our laboratory. We have observed an increased incorporation of labelled adenine and uracil into ribonucleic acids during the induced formation of cytochrome *c*[5], cytochrome peroxidase and catalase[6] in resting yeast (strain 'petites colonies').

The formation of these proteins is induced by oxygen in cells grown anaerobically. The mutant 'petites colonies' never acquires a functional respiratory system, and shows no Pasteur effect. In this strain, oxygen acts merely as an inducer of catalase, cytochrome *c* and cytochrome peroxidase; it is not consumed and cannot be involved in any energy-producing system[5].

The 'petites colonies' mutant was grown anaerobically, the cells washed with water and resuspended in a medium containing glucose, potassium acid phosphate and magnesium sulphate, but without a source of nitrogen or growth factors. They were incubated again for 1 hr. under anaerobic conditions. 8-^{14}C-adenine or 2-^{14}C-uracil was then added to the suspension; one half was shaken in the air, the other under anaerobic conditions. Samples were mixed with 10 per cent trichloracetic acid, the sediment was

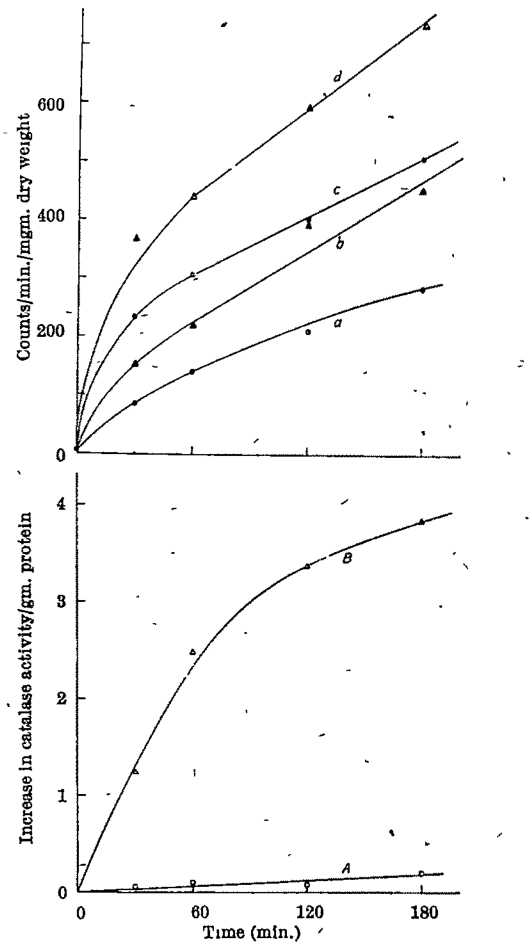

Fig. 1. Incorporation of radioactive carbon from uracil (curves *a* and *b*) and from adenine (curves *c* and *d*) into acid-insoluble compounds. Curves *A* and *B* show the increase in catalase activity per gm. of cell protein. *A*, *a* and *c* are the controls; *B*, *b* and *d* the induced cells

thoroughly washed to remove all acid-soluble compounds, plated, and its radioactivity measured.

The results of such an experiment are shown in Fig. 1. The incorporation of radioactive carbon from adenine or uracil is considerably increased during the induction of the enzyme.

On the other hand, when the same yeast strain was grown under aerobic conditions, it contained large amounts of catalase, which did not increase on further shaking in air. In this case, the rate of incorporation of adenine into nucleic acids was the same under anaerobic conditions as in the air.

The purine bases and the pyrimidine nucleotides liberated by hydrolysis of the nucleic acids were isolated by chromatography. When 8-^{14}C-adenine was added to the yeast suspension, both purines were labelled; when 2-^{14}C-uracil was added, both pyrimidine nucleotides contained radioactive carbon. The specific activities of the four components increased simultaneously during the induction of the enzymes. However, the relative increase was greater for guanine than for adenine, and greater for cytidylic acid than for uridylic acid.

The purines (adenine, guanine, hypoxanthine) from acid-soluble compounds have also been isolated. Their specific activities decreased more rapidly during adaptation than in the control.

It appears from my results that an increased synthesis, or a modification, of nucleic acids is associated with enzyme induction. One may conclude that ribonucleic acid is involved, because the induction increased the incorporation of uracil into the uridylic nucleotide obtained from nucleic acids.

The increased incorporation of adenine caused by the inducer is observed even when enzyme formation is blocked by *p*-fluorophenylalanine. According to Halvorson and Spiegelman's results[7], this analogue inhibits amino-acid utilization for protein synthesis in yeast. It may be concluded that the increased incorporation of adenine does not depend on the actual formation of any new enzyme system. The modification or synthesis of nucleic acid may be a condition for synthesis of induced enzyme; it is not a consequence of the formation of new enzyme molecules.

Ammonium sulphate fractionation of a yeast extract at *p*H 6 gave several fractions containing ribonucleic acid. The specific activities of both adenine and guanine of the different fractions differed considerably, and the percentage increase in specific activity due to enzyme induction was different for each ribonucleic acid fraction. This makes it very probable that the effect observed does not reflect any general change in ribonucleic acid metabolism, and that it involves certain specific nucleic acid fractions which will eventually be isolated.

Response of the Sheep to Sublethal Doses of Fluoroacetate

As part of a study of the capacity of the sheep to metabolize lower fatty acids, the effect of continued administration of sublethal doses of fluoroacetate is being investigated.

Contrary to reports of the action of fluoroacetate on other animals[1], we have found that for sheep its toxicity is profoundly influenced by the route of administration and by the nature of the fodder.

Sodium fluoroacetate (2 mgm. daily) was administered to adult merino sheep (40–50 kgm. body-weight) as follows: 1 mgm./20 ml. water as a drench twice daily, or 1 mgm./5 ml. water as a subcutaneous injection twice daily; 2 mgm./litre of water/day dripped continuously into the abomasum through a fistula; or 2 mgm./litre 0·9 per cent saline/day dripped continuously either into the peritoneal cavity or into the jugular vein. Three groups of animals that were treated in these ways were provided respectively with rations comprised of (*a*) 800 gm. wheaten chaff, (*b*) 800 gm. lucerne chaff, or (*c*) 800 gm. wheaten chaff plus 100 gm. gluten. The concentration of citrate in the blood was determined[2] at regular intervals during treatment.

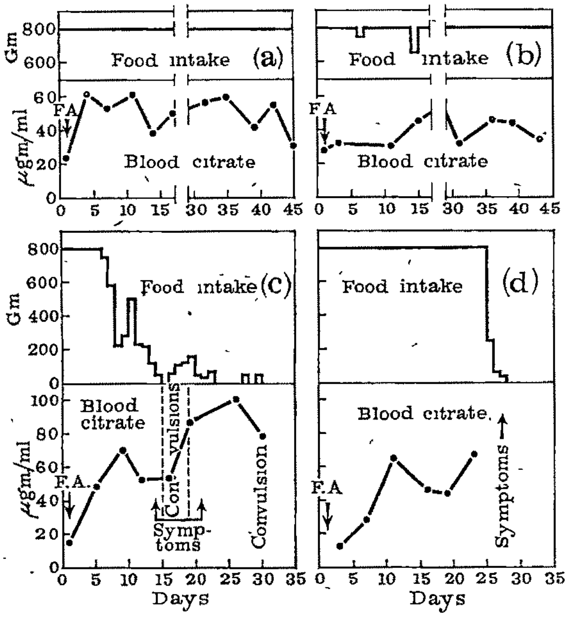

Fig. 1. Food intake and blood citrate-levels of four sheep receiving fluoroacetate. (*a*) Lucerne chaff diet, fluoroacetate drenched; (*b*) wheaten chaff–gluten diet, fluoroacetate drenched; (*c*) wheaten chaff diet, fluoroacetate drenched, (*d*) lucerne chaff diet, fluoroacetate via abomasal fistula

Sheep fed wheaten chaff developed symptoms when fluoroacetate was administered by any of the above routes. Failure to eat the full ration after seven to ten days of treatment and an almost total loss of appetite after twelve to eighteen days were constant features. Some died after a few days of treatment, apparently from heart-block; in the others, muscular inco-ordination and body tremors appeared after fourteen to eighteen days of treatment and culminated in periodic tetanic convulsions of short duration that continued until death ensued a few days later. During this latter stage, the animals that refused all but a small fraction of the ration wheaten chaff readily ate a full ration of lucerne chaff when this was offered, and eventually recovered despite the continued administration of fluoroacetate.

Those on the lucerne chaff ration continued to eat the whole of it and showed no symptoms for periods up to forty-five days, provided the fluoroacetate was administered by drench or by subcutaneous injection. When administered by intravenous injection or via an abomasal fistula, however, death occurred within ten to twenty days, and was not preceded by the characteristic syndrome shown by the animals that were maintained on the wheaten chaff ration: they consumed their ration until a day or so before death and showed no sign of tetanic convulsions.

The group fed wheaten chaff and gluten maintained their appetite and evidenced no symptoms for periods up to forty-five days, during which fluoroacetate was administered either as a drench or a subcutaneous injection.

Three animals in which rumen fistulæ had been established were fed on wheaten chaff, and a supplement of 20 gm. of acetic and 20 gm. of propionic acids adjusted with sodium hydroxide to *p*H 5·5 was introduced each day into the rumen. This supplement, however, did not prevent the symptoms. The sequelæ were identical with those that appeared when wheaten chaff alone was fed.

The symptoms were not closely correlated with the concentration of citrate in the blood. Some animals on wheaten chaff became convulsed during periods when their blood contained 60γ of citrate/ml., whereas others were apparently normal when their blood contained up to 80 γ/ml.

The animals consuming the lucerne rations did not become convulsed after treatment with fluoroacetate *per os*, although the citrate concentrations in their blood rose to 60 γ/ml.

The response of typical animals to treatment with fluoroacetate is indicated in Fig. 1.

The effects of lucerne or of a supplement of gluten suggests that protein may protect the ruminant against sublethal doses of fluoroacetate. Investigations are being continued.

Length of the Muscle Fibres of the Rat Diaphragm

Since its introduction in 1946[1] the phrenic nerve diaphragm preparation from the rat has become one of the most commonly used mammalian nerve–muscle preparations in experimental research. Although indirect stimulation is most often employed, direct stimulation of this preparation has been increasingly used in recent years.

The general opinion is that the directly evoked muscle impulse arises at the cathode and runs along the entire length of the muscle fibre. It cannot, however, traverse the boundaries of the muscle fibre in which it is set up.

When the stimulating electrodes span the entire muscle, all the fibres of the muscle may respond if the current density is high enough to stimulate each fibre individually. With stimulation at one end, however, the response depends on the proportion of the length of the muscle fibres to the length of the muscle, and the whole muscle reacts only if the fibres run the whole length of the muscle[2]. When direct stimulation is applied, it is important to know how great a fraction of the muscle is actually stimulated. Consequently, knowledge of the length of the muscle fibre is valuable. According to Brown and co-workers[3], the length of the single fibres of the rat diaphragm does not exceed 5 mm.

Hajdu and Knox[4] have shown that end-plate potentials can be most easily recorded from a narrow zone midway between the central tendon and the ribs transversely to the fibre direction. That the end-plates are actually localized in this zone with a rather small scatter is easily shown by means of histochemical technique. On stimulating fully curarized preparations either at one end or all over, we have been surprised by the often negligible difference in the height of contractions elicited (Barstad, unpublished work). It therefore seems open to question whether the fibre-length can be limited to 5 mm.

We have tried to elucidate the problem by means of histological as well as electrophysiological technique. Rat diaphragms were cut into strips 5–10 mm.

broad, parallel to the fibres, from the costal insertion to the central tendon. The strips were placed in a saturated aqueous solution of sulphur dioxide[5] at room temperature for eight to fourteen days. They were heated in distilled water to boiling point and then immediately cooled to room temperature. This procedure was carried out four or five times.

After blunt dissection, entire single fibres were isolated with the aid of a binocular of magnification 20. The fibres, both unstained and stained with Heidenhain's hæmatoxylin, were studied under a microscope. The transverse striation was easily observed in all cases.

Twenty single fibres from rat diaphragms were successfully isolated in this way. In each case the fibre could be traced continuously from the costal margin to the central tendon. A greater number of fibres were broken up into two or three parts during dissection. It thus seems very probable that at least some of the fibres run the whole length of the muscle.

To supplement these findings we recorded action potentials from completely curarized isolated rat-diaphragm preparations that were stimulated by electrodes at the costal insertion of the muscle. Square wave pulses with a frequency of 10 per min. and a pulse width of 0·6 m.sec. were supplied by an electronic stimulator with an output of 75 m.amp.

Despite a troublesome shock artefact, it was possible to record potentials close to the central tendon. The decrease in action potential in the tendinous part of the muscle was roughly parallel to the decrease in the proportion of muscle tissue in this part of the preparation as shown in cross-sections stained with hæmatoxylin and eosin.

This finding also indicates that at least a considerable number of the muscle fibres run the whole length of the muscle.

A Radiographic Method for the Study of the Function of the Cow's Udder

In studying the function of the milk gland, with the view of increasing milk production, particular attention has been devoted in recent years to the milk-ejection mechanism (the let-down reflex). Ely and Petersen[1] demonstrated the important part played by oxytocin in milk ejection; Grachev[2] and Barishnikov *et al.*[3] emphasized the influence exerted by the central nervous system.

In almost all the reports available, the methods of studying the let-down reflex have been based upon catheterization of the udder and the measurement of changes in pressure within the udder during different phases of milking. Contradictory findings obtained in this way may be attributable to variation in details of technique, such as the diameter of catheter used, depth of insertion, or possibly irritation of the udder by the indwelling catheter.

We have attempted to develop a method which would permit objective registration of motor activity in the udder. This method consists of demonstration by X-rays of changes within the collecting ducts and cisterns of the udder by means of a contrast medium filling this system.

Preliminary experiments were carried out using isolated cow's udders. The suitability of various contrast media, the technique of filling the milk ducts and cisterns, and the amounts of medium required were worked out. 'Ultraren' (aqueous iodide solution) proved the most satisfactory contrast medium, and 20 ml. sufficed to display the cistern of one milk gland of an udder of average size.

The method was then tested in a cow (No. 80, red spotted breed) with low milk production (3 litres daily) which had recovered from mastitis of the left posterior quadrant. Tests were preceded by a period of acclimatization to experimental conditions. Thus, the cow was accustomed to the X-ray room, gradual darkening of the room, the sound of the X-ray apparatus, etc., by being milked under identical conditions at the same time daily. She seemed entirely accustomed to the experimental environment after ten days. Adaptation was considered complete when the milk yield in the X-ray room equalled that obtained under normal conditions in the cow-shed.

Preparation for radiographic study was then carried out as follows. The tip of the teat was gently wiped, and a fine sterile rubber catheter introduced. A 'Nelaton' catheter No. 2 was used, dipped in 'Pateol' (urological antiseptic lubricant). The procedure caused no defensive reaction in the cow. About 20 ml. of milk was allowed to drip from the catheter, 20 ml. of contrast medium was slowly injected, and the catheter withdrawn. A 35 per cent solution of 'Ultraren', heated to 37° C., did not seem to cause any irritation of the udder, as evidenced by no change in radiographic appearance. The following is a brief report of some of our observations made using this method.

After mechanical stimulation of the teat filled with contrast medium, such as squeezing several times as in milking, contractions of the distal portion of the cistern, most marked in the central section of the teat, appeared within a few seconds. The shadow, initially of smooth cylindrical shape, developed an hour-glass constriction.

If a teat on the opposite side of the udder was similarly stimulated, contraction occurred after a delay of about one minute. Contractions were periodic and continued for about 15 min. The duration of each contraction was 7–15 sec., their frequency 1–2 contractions a minute. With contractions, the contrast medium was forced to the roof of the cistern, and after several contractions reached the larger milk ducts. It was possible to demonstrate that this was not merely due to simple diffusion of the contrast medium.

The relationship between contraction of the cisternal smooth muscle and milk ejection evoked by administration of oxytocin was also investigated. It was found that intravenous injection of oxytocin in dosages sufficient to cause milk ejection was not associated with contractions as described above.

The effect of squeezing the teat during milking was also noted. Following such squeezing of the base of the teat at the beginning of milking, the contrast material was observed to rise in the cistern and spurt into the milk ducts, as in isolated udder preparations.

On the basis of these preliminary observations, we believe this method is a promising one for investigation of the motor function of the udder, and hope in future investigations to re-assess current theories as to the nature of this process.

Region *E* and the S_q Current System

The equilibrium equation for the electron density N in a solar-controlled ionospheric region, such as normal region E, is, with the usual nomenclature:

$$\frac{\partial N}{\partial t} = q_0 \cos \chi - \alpha' N^p - \operatorname{div}(N\mathbf{v}) \qquad (1)$$

where χ is the solar zenith angle, α' the effective recombination coefficient and $\mathbf{v}$ the vector drift velocity; q_0 is proportional to the intensity of the solar ionizing radiation. The solution of this equation has been discussed by Martyn[1] and by Appleton and Lyon[2]. At or near noon, $\partial N/\partial t \doteqdot 0$, and if the movement term $\operatorname{div}(N\mathbf{v})$ is small, the critical frequency fE is related in a simple manner to χ, and we can write:

$$(fE)^n = K \cos \chi \qquad (2)$$

K is a constant, $n = 2p$ and for an isothermal region has the value 4 for recombination and 2 for attachment. In practice, it is found that the values of n deduced from the approximate equation (2) usually lie between 2 and 4, and this has been interpreted by most workers as evidence for a height gradient in the effective recombination coefficient or non-isothermal conditions in the layer. An alternative approach, and one which we adopt here, is to suppose that the apparent variations in n with time and place may result at least partly from neglect of the movement term $\operatorname{div}(N\mathbf{v})$.

It is now generally believed that the S_q magnetic current systems are located at or near the level of region E, and Martyn[3] has shown that vertical drift may be expected to modify the electron density distribution at places where the current systems have east–west components. Such modifications will appear in fE and these in turn may influence the index n. Curve A in Fig. 1 shows average values of n deduced (by the method of least squares) from equation (2), using monthly mean noon values for the years 1952–54 for all available stations in a longitude zone centred approximately on the 150° E. meridian. For these years of low solar activity only minor corrections for changing month-to-month activity were necessary. It will be seen that there is a clear variation of n with latitude, with quite marked singularities at or near Tokyo and Watheroo. These stations are situated near the mean latitudes of the foci of the S_q current systems, and it seems probable that the singularities in the curve are to be associated with the fact that the foci are overhead at approximately 1100 hr.

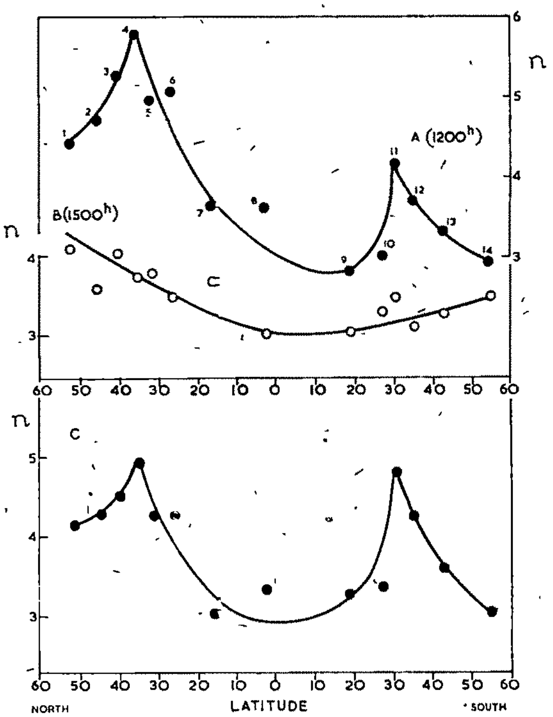

Fig. 1. Index n for stations centred approximately on the 150° E. meridian, derived from values of fE for 1952–54. Curve A: 1200 hr.; curve B: 1500 hr.; curve C: 1200 hr. reduced to common solar distance.

1, Adak. 2, Wakkanai. 3, Akita. 4, Tokyo. 5, Yamagawa. 6, Okinawa. 7, Baguio. 8, Singapore. 9, Townsville. 10, Brisbane. 11, Watheroo. 12, Canberra. 13, Hobart. 14, Macquarie Island

The values of n are a measure of the seasonal variation in fE, and depend quite markedly on any differential influence between seasons. In January the solar distance is some 3 per cent less than in July, and when the appropriate small corrections are made to the monthly mean values of fE to allow for this, the marked asymmetry in curve A is largely removed (Fig. 1, curve C). The small residual differences between stations in the higher northern and southern latitudes may possibly be due to the magnetic asymmetry of the Earth.

We have made a similar study for two other longitude zones (centred on 10° E. and 70° W.) and find confirmatory evidence for these singularities north and south of the equator. Now magnetic studies show that, in summer, the current systems are much stronger than in winter, and also that the foci are then some 10° nearer the equator. At the foci, no vertical drift will occur; at higher latitudes (current towards the west) drift will be downwards, and at lower latitudes (current towards the east) drift will be upwards. Martyn and also Appleton and Lyon have shown that the changes in electron density to be expected as a consequence of vertical drift depend on both the velocity of drift and on the height-gradient of this velocity. If downward drift is associated with a decrease in fE, and vice versa, then an explanation for the marked peaks in n near latitudes 35° N. and 30° S. can be formulated

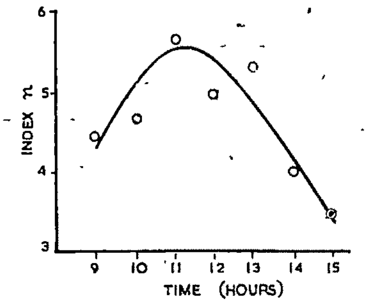

Fig. 2. Index n for various hours at Tokyo (1952–54)

in terms of vertical drift assuming that, with change of season, the foci of the current systems move north–south across these latitudes and the current intensity varies in the manner indicated by magnetic studies[4].

The S_q current system moves around with the Sun, and near 1500 hr. at all latitudes less than about 70° the east–west component is very small, so that vertical drift effects may also be expected to be much reduced. We have calculated the index n from the seasonal variation in fE at 1500 hr. at all stations. These values are shown in Fig. 1, curve B, and it will be seen that they are generally less than at noon, and that at this hour no peaks appear at any latitude. This remarkable change between 1200 and 1500 hr. tends to confirm that our interpretation of Fig. 1, curve A, is probably valid. Moreover, when the influence of the current systems is removed, there appears to be a gradual decrease in n towards the equator. This may be evidence for a change in E-layer characteristics (such as vertical temperature gradient) from temperate to equatorial latitudes.

For certain stations we have also calculated the index n for each hour between 0900 and 1500, and the values found for Tokyo are plotted in Fig. 2. In these calculations the appropriate corrections for the equation of time and varying sunspot number and solar distance have been made. It will be seen that the variation over the day is markedly asymmetric, forenoon values being considerably larger than those at corresponding afternoon times, and the peak value is not at noon but at about 1100 hr. This type of variation is just that to be expected, since the east–west component of the S_q current system, and hence vertical drift effects, are a maximum an hour or so before noon.

If 'normal' values of fE (that is, those unaffected by S_q effects) occur when the focus is overhead, we can estimate the approximate order of magnitude of the change in region E ionization at various latitudes as a result of vertical drift. For the latitude of Tokyo, our results suggest that in June and December the peak ionization density is respectively decreased and increased by some 3–4 per cent, whereas at the equator the corresponding increase seems to be about 10 per cent. It is to be emphasized that the fE perturbations involved are very small and these figures are only approximate indications of the orders of magnitude. However, the experimental results certainly indicate a marked increase in vertical drift effects towards the equator, a conclusion which is in accordance with theoretical considerations.

A more extended study shows that region E exhibits a number of departures from a Chapman-type layer, and it is now clear that these are largely, if not entirely, to be explained in terms of vertical drift.

We have made a similar study of n for region F and find that although there is some evidence f anomalous values near the latitudes of the curre foci, there are no sharply defined maxima of th kind found for region E. A more detailed discussio of these and other results will be published elsewher

The above work was carried out as part of th programme of the Radio Research Board of th Department of Scientific and Industrial Researc and this is published by permission of the Direct of Radio Research.

Note added in proof. Appleton *et al.* have recent published (*Nature*, 176, 897; 1955) a description work which provides other ionospheric evidence f the influence of the S_q current system in region E.

Determination of the Thickness of Ice Shelves by Seismic Shooting Methods

Seismic soundings of the thickness of the floati ice shelves of Antarctica have so far been attempte by two expeditions, the Second Byrd Antarct Expedition of 1933–35[1], and the Norwegian–Britis Swedish Antarctic Expedition 1949–52[2,3]. Furth measurements are likely to be made by sever expeditions during the International Geophysic Year 1957–58.

Reports which have appeared to date do not gi a satisfactory interpretation of the detailed recording The reasons for rejecting Poulter's earlier interpreta tion[1], which assumed that sea water percolat through ice shelves to sea-level, have already bee outlined[2]. My preliminary report[2] used an empiric method, based on the known thickness of ice at o station, to interpret the travel times of echoes other stations in terms of thickness, as the detaile interpretation of the echoes was not clear. Th method indicated that the ice shelves were of almo uniform thickness, a result which appeared to one's experience of these features.

Now that a detailed study of the results has bee made, this picture has proved to be inconsistent wi various related observations. A new and consiste interpretation of the results is therefore proposed.

The major inconsistency found was the lack agreement of ice thickness with the surface heig of the ice shelves. These heights proved to be mo accurate than originally anticipated, the standa deviation for ten measurements at different times f a station at 115 km. from Maudheim being 3·3 The variation of surface height with the prelimina estimates of ice thickness shown in Table 1 cou only be explained by large variations in the me density of the ice shelf with location. Poulter h actually used his results to make such deductio However, detailed interpretation of the seism velocity–depth curves shows that depth–densi profiles in Queen Maud Land do not vary rapid with location. Assumptions such as varying ro loads carried at the bottom of the ice fail to satis the density variation which would be needed correlate surface heights with the preliminary esti

* Seismometers 100–150 m. from shot point.

ates of thickness. In addition, mean densities necessary for such correlation would not fit the values obtained by Schytt[4] at Maudheim to a depth of 100 m., as do the new mean densities shown in Table 1.

In order to interpret the results in a way consistent with the surface height observations, it is necessary to assume that we have been dealing with the second reflexion of a *P* wave at station 178, but with the first reflexion of the *P* wave at the other four stations. The arrival times of the main reflected pulses are shown in Table 2, tabulated according to the new interpretation. The pulse now interpreted as being the *PS* phase at station 170 was originally assumed to be the same as the triple reflexion of the *P* wave at 178, and was considered to favour the preliminary method of interpretation. Confirmation as to whether or not this is the *PS* phase could be obtained by future workers measuring the horizontal component of motion, which should be much larger than the vertical component for short spreads such as we used. Both the vertical component of amplitude in relation to that of the *P* wave reflexion and the mean arrival time of this pulse are of the correct order for the *PS* phase, but, as the spread of arrival times over the six seismometers appears to be about double that calculated, some doubt remains.

Another check on the new interpretation is provided by working out the reflexion coefficient for the energy reflected by the ice-water interface after making allowance for attenuation of the *P* waves. This has been done by measuring the amplitude of successive multiple reflexions, and agreement with the theoretical value is much closer than that provided by the preliminary figures. Finally, a pulse on the records at 178 has been recorded which arrives in the middle of the Rayleigh waves and is apparently the first *P* reflexion at this station. The clarity of the pulse was not sufficient to be taken as an echo on its own merits, but in view of the foregoing it is now assumed to be the first reflexion.

The revised interpretation of the results is shown in Fig. 1. Full use has been made here of the surface heights of the ice shelves in order to estimate changes in ice thickness.

The idea of an approximately constant equilibrium thickness of ice shelves of about 200 m., which was expressed in the preliminary publications, is not correct. It still appears likely that an approximate equilibrium thickness is maintained at a given locality, as indicated by surface levelling at different times at Maudheim, but this 'equilibrium thickness' obviously varies with position. Consequently any equation relating accumulation and spreading of ice sheets must also take into account variations of thickness as the ice shelf moves forward.

The proposal that 'ice hills' form where there is insufficient depth of water to float an ice shelf, which would otherwise be expected to be present, fits the new interpretation of observations still more closely than the earlier interpretation.

As regards the section of the profile over which the ice was resting on rock, no significant changes in

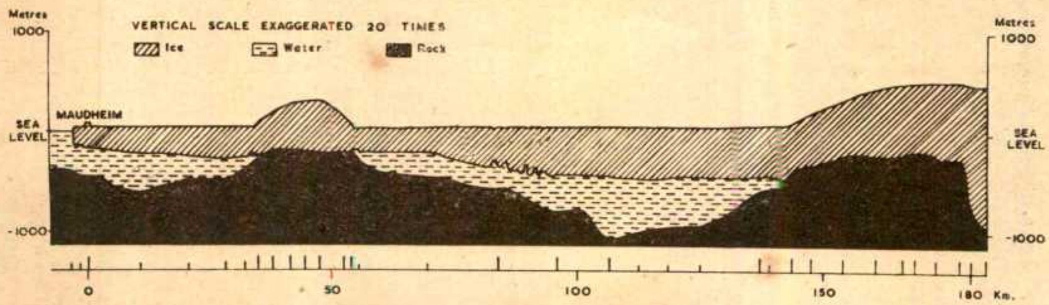

Fig. 1. Main seismic profile. The long vertical lines above the distance scale show points at which echoes were obtained from the bottom of the ice, while the short lines indicate points at which echoes were recorded from the sea bottom only

interpretation from the preliminary publications have resulted from the more detailed study.

Control of the Staining Procedure after Paper Electrophoresis

WHEN quantitative techniques are attempted for the analysis of serum proteins separated by electrophoresis on filter paper, it is recognized that the staining procedure, followed by removing the surplus stain, constitutes sources of error. In order to get more satisfactory reproducibility we apply on each paper strip (after electrophoresis but before staining) 0·02 ml. of a 0·05 per cent solution of polyethylenimine (Badische Anilin und Sodafabrik, Ludwigshafen (Germany)) in water. This polybase, $-[-CH_2-CH_2-NH_2-]_n-$, has the advantage of being stained by naphthalene black 12 *B* as well as by sudan black; therefore it can be used equally well as a reference substance for protein staining and lipoprotein staining. The molecule (mol. weight approx. 30,000–40,000) of the polybase (called 'Polymine') is of linear build and possesses such an affinity for cellulose that the stained spots cannot easily be eluted but must be estimated by direct-reading colorimetry. The paper strip *a* (see Fig. 1) shows the separation of normal serum proteins (Whatman paper No. 1, *p*H 8·6, 10 V./cm.) and a spot of 0·02 ml. 'Polymine' standard on each side. Strip *a* has been stained with naphthalene black and strip *b* with sudan black. It is well known that in pathological sera the uptake of dyes is variable; in such cases the 'Polymine' standard can serve as a reference because the solubility interrelationships between dye, solvent and polybase are constant.

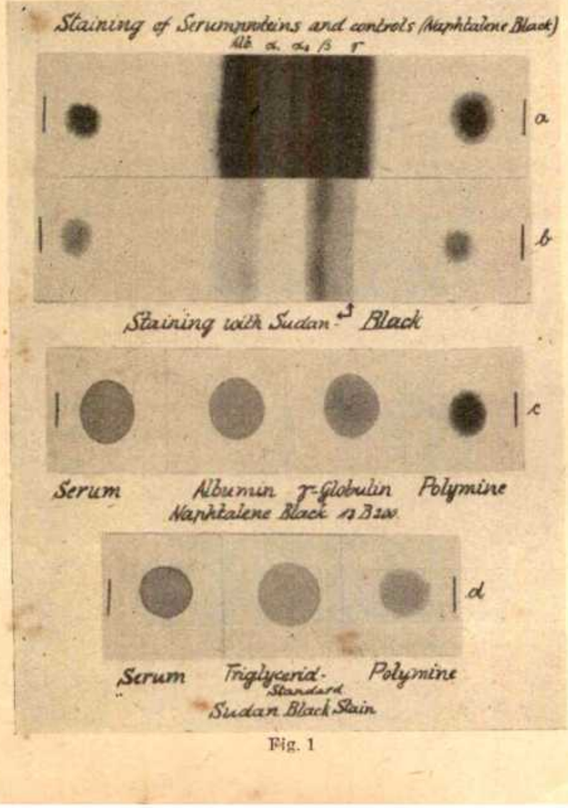

Fig. 1

Table 1

	Volume (ml.)	Amount (γ)	Planimeter reading	First standard deviation
Stained with naphthalene black				
Serum, dil. 1 : 40	0·02	35	0·92	1·8
Albumin, human	0·02	30	0·90	1·7
γ-Globulin, human	0·02	30	0·83	1·6
'Polymine' (0·05 per cent)	0·02	10	1·00	2·0
Stained with sudan black				
Serum, dil. 1 : 1	0·02	150 (lipids)	1·25	1·7
Triglyceride-standard	0·02	80	1·20	1·5
'Polymine' (0·05 per cent)	0·03	15	1·00	2·7

On paper strip *c* the staining of some proteins with naphthalene black is compared with the staining of the 'Polymine' standard on the right. Paper strip *d* is stained with sudan black; in the middle section there is a drop of 0·02 ml. of triglyceride standard, containing 60 γ of triolein and 20 γ of tristearate, which we have used[1] as reference for lipoprotein staining. The spot on the left of it is a drop of 0·02 ml. of normal serum diluted 1 : 1 with sodium chloride (physiol.). The dye uptake of such a drop gives a fair measure of the total lipids of the serum. Table 1 shows the mean results of twenty-five spots of each substance, as read in the electronic densitometer Model 525 of the Photovolt Corp.

The different diffusion (spread) of the spherical colloids (proteins) and the linear colloid ('Polymine') is noticeable.

A New Solvent for Quantitative Paper Chromatography of Sugars

MANY mobile phases are found in the paper chromatography of sugars; but the separation of sucrose, fructose and glucose is somewhat difficult, because their R_F values are very near each other[1]. The separation is enough for identification purposes, but it is not good enough for elution or photometric readings, because the sugars are still partly mixed. The solvent suggested below divides the sugars quite well with the following R_F values (at 20° C.): sucrose, 0·17; glucose, 0·26; mannose, 0·30; arabinose, 0·32; fructose, 0·32; xylose, 0·33; ribose, 0·41.

The solvent, which was studied for non-volatile organic acids[2], is: normal propyl alcohol, 50 c.c.; benzyl alcohol, 72 c.c.; water, 20 c.c.; 85 per cent formic acid, 20 c.c. It must be freshly prepared. The photometric readings give with this solvent a graph of well-separated curves, so that errors due to the computation of common areas are eliminated.

It is preferable to evaporate the solvent with warm air before spraying with the reagent.

Ultra-Violet Absorption of Oxygen in Organic Solvents

It has been found that, in a number of organic solvents, dissolved oxygen gives rise to absorption in the far ultra-violet. This absorption is completely eliminated when oxygen is removed by boiling, or by bubbling nitrogen or other gases through the solvent.

In Fig. 1 are shown spectra of cyclohexane at 30° C. in equilibrium with oxygen at several partial pressures. In the wave-length range studied, the absorbance due to oxygen is found to be directly proportional to the partial pressure of oxygen above the solution. Similar spectra have been obtained with *n*-hexane, *n*-heptane, methanol, ethanol and diethyl ether.

To determine whether the absorption might be due to free oxygen, the solubility of oxygen in cyclohexane was measured. At a partial pressure of one atmosphere, approximately 0·27 vol. of oxygen (reduced to standard temperature and pressure) dissolves in one volume of cyclohexane. The absorbance of an equivalent concentration of gaseous oxygen is negligible in the spectral range considered, so the absorption of the solution must be due to interaction between oxygen and the solvent.

Assuming that this interaction results in the formation of a molecular complex which is in turn responsible for the absorption, a reaction of the form $mO_2 + nS \rightleftharpoons (O_2)_m{\cdot}S_n$ with equilibrium constant $k = a_c/a_0{}^m a_s{}^n$ may be supposed to apply, where O_2 is oxygen, S is solvent, m and n integers, and a_c, a_0 and a_s are the activities of the complex, oxygen and solvent respectively. For the activity of oxygen the partial pressure p may be substituted. Assuming, furthermore, that the solution is ideal and that Beer's law holds for the complex, a new equilibrium constant is found: $k' = D/p^m x^n$ (D is the absorbance at a given wave-length due to the complex, and x is the mole fraction of solvent).

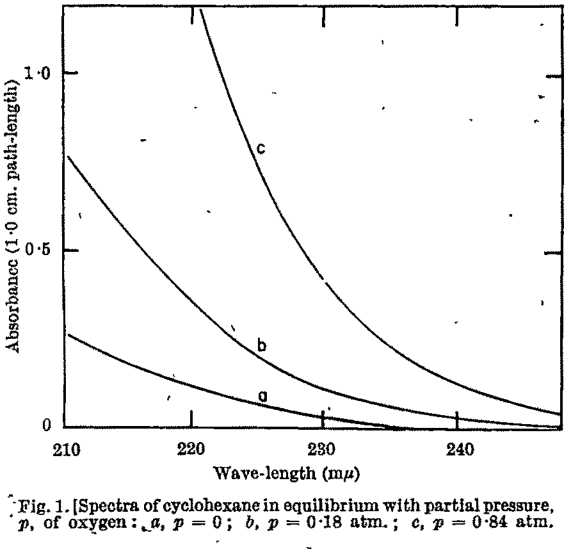

Fig. 1. [Spectra of cyclohexane in equilibrium with partial pressure, p, of oxygen: a, $p = 0$; b, $p = 0{\cdot}18$ atm.; c, $p = 0{\cdot}84$ atm.

As the solvent is present in large excess, x is essentially independent of p. Consequently, from the proportionality of D to p, one must conclude that $m = 1$.

The value of n was found by determining the dependence of absorbance on solvent composition, for a series of mixtures of cyclohexane and *n*-heptane at a given partial pressure of oxygen. The absorbance was considered to be the sum of the absorbances of the cyclohexane and of the *n*-heptane complexes, the contributions of each being governed by the separate equilibrium constants k'.

As oxygen absorbs considerably less in *n*-heptane than in cyclohexane, although equally soluble in the two solvents, definite conclusions could be drawn only with regard to the latter. The results indicate that, for cyclohexane, $n = 1$; or, in other words, cyclohexane and oxygen form a 1 : 1 molecular complex.

This investigation was supported by a grant-in-aid from the American Cancer Society upon recommendation of the Committee on Growth, National Research Council. One of us (J. F. S.) was a Scholar in Cancer Research of the American Cancer Society.

Ectotrophic Mycorrhiza in Renantherous Species of *Eucalyptus*

There appear to be in the literature no detailed studies of mycorrhiza in *Eucalyptus*. Brief references are made by Samuel[1], in South Australia, and Smith and Pope[2], in South Africa.

It might be thought mycorrhiza plays no significant part in success or failure of *Eucalyptus* introductions since so many species have been successfully cultivated as exotics in numerous countries. While this is true of *Eucalyptus* as a whole, introduction records show that species of the group *Renantherae* are largely exceptional to this.

The failure of the *Renantherae* is striking when it is realized that they have been introduced on many occasions because they contain a larger percentage of good timber species than any other group of the genus. The situation is well illustrated by records from Cyprus. Chapman[3] lists twenty-one renantherous species in a total of about seventy introductions since 1878; but not one of them could be found growing on the island in 1953, although representatives from all other groups were found.

Table 1

	Heat-sterilized soil + *Scleroderma* spores			Heat-sterilized soil		
	Growth* (6 mths.) (in.)	Colour	Mycorrhiza	Growth* (6 mths.) (in.)	Colour	Mycorrhiza
Renantherae						
E. dives	5·3	Normal green	Abundant	3·2	Yellowish	Nil
E. pauciflora	6·2	Normal green	Common	3·3	Yellowish	Nil
E. macrorrhyncha	11·3	Normal green	Abundant	7·8	Yellowish	Nil
Macrantherae						
E. bicostata	9·5	Normal green	Nil	8·3	Normal green	Nil

* Average maximum growth in height. There were many seedlings per pot

The *Renantherae* have been found on genetic grounds to be a very distinct natural unit within the genus *Eucalyptus*[4]. They differ from the rest of the genus in many respects, and this led to the idea that their mycorrhizal requirements may also differ. Experience in Iraq in 1953 at the forest nursery at Eski Kellek supported this view. Here some eucalypts grew easily, and the plants were as healthy and vigorous as stock of a similar age grown under comparable conditions in Australia. Species of the *Renantherae*, however, raised there at the same time, were weak and chlorotic and mostly died. The particular species were *E. dives*, *E. pauciflora*, *E. robertsonii* and *E. fastigata*. Afterwards, in Australia, at Canberra, similar symptoms were induced in the same species by growing them in soil sterilized by heating. This effect is contrary to that commonly obtained using sterilized soil, as Stahl[5] demonstrated by his well-known experiments, and indeed his results apply to most *Eucalyptus* species other than the *Renantherae*.

Trials were continued to test the idea that lack of mycorrhiza was responsible for failure. Three species of the *Renantherae*, *E. dives*, *E. pauciflora* and *E. macrorrhyncha*, were used and compared at the same time with *E. bicostata*, belonging to the group *Macrantherae-Normales*. Pot cultures using spores from fruiting bodies of the gasteromycete, *Scleroderma flavidum*, were made for comparison with plants in sterilized soil to which spores were not added. *Scleroderma flavidum* was chosen because its fruiting bodies are found closely associated with *E. pauciflora* and *E. robertsonii* in experimental plantations near Canberra. Spores were applied liberally ½ in. below the final surface and the pot was then filled up with more heat-sterilized soil so that the growing roots had to pass through the spore layer. After four months there were distinct differences, as shown in Table 1.

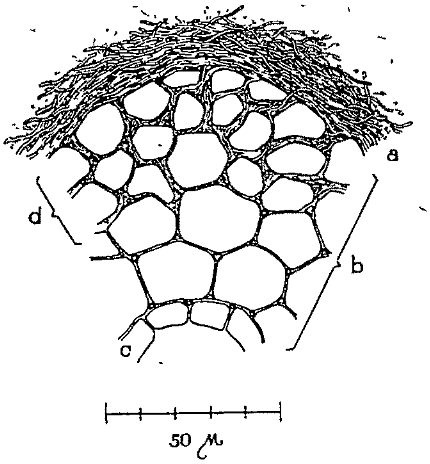

Fig. 1. Cross-section of a mycorrhiza of *E. macrorrhyncha* and *Scleroderma flavidum*, showing (*a*) hyphal mantle, (*b*) cortex, (*c*) endodermis, (*d*) Hartig net

Good growth and good colour in the *Renantherae* were accompanied by the development of mycorrhiza following the application of *Scleroderma* spores, whereas *E. bicostata* grew equally well with or without the spores and did not produce mycorrhizas. The mycorrhizas in the three renantherous species were clearly visible on the outside of the ball in the pot and consisted of a thick hyphal mantle and a coralloid branching habit characteristic of the ectotrophic mycorrhiza of some hardwoods. Microscopic examination of that on *E. macrorrhyncha* showed a dense, thick hyphal mantle outside the root epidermis with a distinct Hartig net penetrating to a depth of two or three cortical cells, and exhibiting a structure (Fig. 1) closely comparable with that of ectotrophic mycorrhiza figured by Björkman[6]. The experiment shows, therefore, that *Scleroderma flavidum* is able to form an ectotrophic mycorrhiza with three renantherous species and that these grow healthily in heat-sterilized soil if *Scleroderma* spores are added; but they do not form mycorrhizas and grow poorly in soil sterilized by heating if no fungus is added. While it is probable that ectotrophic mycorrhiza occurs in species in other groups of the genus, it seems clear that it is not essential for thrifty growth in these. The experiment and observations suggest that the failure or indifferent growth of many species of the *Renantherae* in the northern hemisphere may be corrected by inoculation with the appropriate fungus. Some of the best timber-producing species are renantherous, such as *E. regnans*, *E. fastigata*, *E. gigantea*, *E. pilularis*, *E. marginata* and *E. obliqua*.

There are reasons for thinking that the situation may differ in the southern hemisphere, and there are records of satisfactory growth of renantherous species in both New Zealand and South Africa. It may well be that there is a degree of affinity in the fungal flora of these three countries, as is the case with the higher plants, which leads to the presence of adequate mycorrhiza-forming fungi.

A more detailed account will be published elsewhere. I am indebted to Dr. Erwin Gauba for the microscopic preparation and to Mr. O. Ruzicka for the drawing.

FORTHCOMING EVENTS

*(Meeting marked with an asterisk * is open to the public)*

Monday, March 26

Chemical Society (in the Great Hall, The University, Nottingham), at 9.30 a.m.—Symposium on "Antibiotics and Mould Metabolites".

Pharmaceutical Society of Great Britain (at 17 Bloomsbury Square, London, W.C.1), at 7 30 p m —Dr. E. F. Hersant · "Analysis and the Pharmacist".

Tuesday, March 27

Chemical Society (in the Great Hall, The University, Nottingham), at 10.45 a.m.—Prof. W. Wardlaw: "Alkoxides, Old and New" (Presidential Address).

Bone and Tooth Society (at the Institute of Orthopædics, 234 Great Portland Street, London, W 1), at 5 p.m.—Symposium on "Bone Tumours". Dr. A. D. Thomson. "The Classification of Bone Tumours"; Dr. C. H G. Price: "Primary Osteogenic Tumours of the Skeleton and Their Relationship to Bone Growth and Metabolism"; Dr. H. A. Sissons: "Experimental Bone Tumours".

Chadwick Trust (at the Royal Society of Health, 90 Buckingham Palace Road, London, S.W.1), at 5 30 p.m.—Dr. B. A. Southgate: "A Survey of Progress in the Control of Stream Pollution"* (Chadwick Public Lecture).

Institution of Electrical Engineers, Measurement and Radio Sections (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. E. Franklin and Mr. J B James: "The Applications of Transistors to the Trigger, Ratemeter, and Power Supply Circuits of Radiation Monitors".

Royal Aeronautical Society (at 4 Hamilton Place, London, W 1), at 7 p m.—Mr. J F. Harper · "The Rise of the Aircraft in Pest Control Agriculture".

Society of Instrument Technology (at Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Mr. R. K. Sandiford: "Atomic Energy Plant Instrumentation".

Wednesday, March 28

*Chemical Society (in the Great Hall, The University, Nottingham), at 11 a.m.—Prof Dr. Otto Hahn · "Personal Reminiscences of a Radiochemist" (Faraday Lecture).

British Nuclear Energy Conference (in the Lecture Hall, The Institution of Mechanical Engineers, 1 Birdcage Walk, London, S W.1), at 3 p.m.—Symposium on "Nuclear Energy".

Physical Society, Colour Group (at the Victoria and Albert Museum, South Kensington, London, S.W.7), at 3.15 p.m.—Annual General Meeting. 3 30 p.m.—Mr H. L. Gloag and Dr. R. G. Hopkinson: "Colour and Lighting in Buildings".

British Institution of Radio Engineers, London Section (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6.30 p m.—Mr. K. E. Harris: "Some Problems of Secondary Surveillance Radar".

Society of Chemical Industry, Chemical Engineering Group (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Mr. F Seligman: "Some Aspects of the Use of Radio-Isotopes".

Society of Chemical Industry, Food Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6 30 p.m.—Dr. Frank Wokes and Mr. John J. Doherty. "The Use of Recovery Experiments in Fluorimetric Assays of B Vitamins in Food"; Dr. J. M. Shewan and Dr N. R. Jones: "Chemical Changes Occurring during the Spoilage of Chilled Fish and their Relation to Freshness Tests".

Oil and Colour Chemists' Association (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 7 p.m —Dr J. E. O. Mayne: "Current Views on How Paint Films Prevent Corrosion".

Royal Aeronautical Society (at 4 Hamilton Place, London, W.1), at 7.30 p.m.—Mr A. V. Cleaver: "Artificial Space Satellites".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Scientific Officer, Grade 1 (with a university degree of high standard with chemistry as a major subject, or equivalent qualifications, and preferably some research experience) in the Defence Standards Laboratory, Department of Supply, Maribyrnong, Victoria, Australia, to carry out research on explosives, particularly in the fields of initiation and detonation—The Senior Representative AP.48), Department of Supply, Australia House, Strand, London, W.C.2 (March 29).

Senior Lecturer (with a university degree and good industrial and/or teaching experience) in Electrical Engineering, to teach electrical engineering measurements and servo-mechanisms to post-Higher National Certificate standard, and to be responsible for organizing laboratories—The Principal, School of Electronics (Ministry of Supply), Radar Research Establishment, Malvern, Worcs March 29).

Physicist (preferably with an honours degree in physics or mathematics) in the Nuclear Power Branch at Headquarters in London, to take charge of a small section responsible for the theoretical and economic aspects, and longer-term applications of nuclear power, and the physics problems arising therefrom—The Director of Establishments, Central Electricity Authority, Winsley Street, London, W.1, quoting Ref. ND/6 (March 30)

Lecturer in Mathematics—The Principal, Borough Road College, Isleworth (April 2).

Lecturer (with special qualifications in physical chemistry or in inorganic chemistry) in the Department of Chemistry—The Registrar, University College, Singleton Park, Swansea (April 4).

Lecturer (with a good university degree, preferably in electrical engineering, and a special interest in, and experience of, electrical engineering materials, for example. solid and liquid dielectrics, insulation, and magnetic materials) in Electrical Engineering—The Registrar, The University, Birmingham 15 (April 6)

Demonstrator or Assistant Lecturer (with a good honours degree in physiology, biochemistry or chemistry with subsidiary physiology) in the Department of Physiology—The Registrar, The University, Manchester 13 (April 9)

Head (with high academic qualifications, preferably an honours degree in mining, practical mining experience, and teaching experience) of the Mining and Geology Department—The Principal, Wigan and District Mining and Technical College, Wigan (April 9).

Lecturer in Chemical Engineering—The Principal, College of Technology, Manchester (April 9).

Reader or Senior Lecturer in Veterinary Anatomy at Makerere College (University College of East Africa)—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (April 12).

Entomologist (with an honours degree in zoology or other suitable qualification) for fundamental and applied research on insect pests of sugar beet—The Secretary, School of Agriculture, Cambridge (April 14).

Lecturer in Biochemistry—The Secretary, The University, Exeter (April 14).

Lecturers (2) in the Department of Mechanical Engineering—The Registrar, The University, Liverpool (April 14).

Population Ecologist (with an honours degree in science, preferably with research experience in the problems of insect population ecology) in the Division of Entomology, Commonwealth Scientific and Industrial Research Organization, Canberra, A.C.T, Australia, to be one of a group of ecologists working on fundamental field and laboratory studies, under the leadership of Dr. A. J. Nicholson, in particular studying the factors which regulate the abundance of certain forest and orchard pests—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C 2, quoting Appointment No. 180/105 (April 14).

Research Meteorologist (with a university honours degree in meteorology, physics or mathematics, and postgraduate experience of research in synoptic and dynamic meteorology) in the Division of Meteorological Physics, Commonwealth Scientific and Industrial Research Organization, Australia, to join a small group working on certain fundamental aspects of dynamic meteorology and the general circulation, and on intensified studies of some local synoptic problems, for example, the cold front of S E Australia—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 420/94 (April 14).

Lecturer (with special qualifications in physical and/or inorganic chemistry) in Chemistry, in St. Salvator's College—Joint Clerk to the University Court, The University, College Gate, St. Andrews (April 15).

Assistant Lecturer in Zoology—The Registrar, The University, Manchester (April 16)

University Demonstrator (with a broad scientific education, and experience in some branch of chemical engineering, mechanical engineering or physics) in Chemical Engineering—The Secretary of the Appointments Committee, Department of Chemical Engineering, The University, Tennis Court Road, Cambridge (April 17).

Lecturer in Mathematics in St Salvator's College—Joint Clerk to the University Court, The University, College Gate, St. Andrews (April 21).

Assistant in Physiology—The Secretary of University Court, The University, Glasgow (April 30).

Lecturer in Physiology—The Secretary of University Court, The University, Glasgow (April 30)

Lecturer or Assistant Lecturer in Clinical Parasitology in the Veterinary School—The Registrar and Secretary, The University, Bristol (April 30).

Lecturer (preferably with a medical qualification, and some experience in teaching and research) in Pharmacology, at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong, April 30).

Lecturers (2) (with good academic qualifications and practical experience) in the Department of Mechanical Engineering—The Registrar, The University, Bristol 8 (April 30).

Professor of Nuclear Physics and Director of the Nuclear Physics Research Unit, at the University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, April 30).

University Students and Fellows for research in experimental or theoretical nuclear physics—The Professor of Natural Philosophy, The University, Glasgow (April 30).

Geologist (with a degree or equivalent in geology, and a satisfactory knowledge of (*a*) petrology and mineralogy or (*b*) the geology and mapping of glacial and other unconsolidated deposits, or (*c*) stratigraphy and palæontology) in the Irish Geological Survey—The Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin (May 17).

Assistant Lecturer and a Lecturer in the Department of Applied Mathematics—The Registrar, The University, Liverpool (May 23).

Associated Electrical Industries Fellows (2), one in the Department of Physics and one in the Department of Engineering—The Secretary-General of the Faculties, University of Cambridge, The Old Schools, Cambridge (May 31).

Assistant, Grade B (preferably with an honours degree, and with either teaching, research or industrial experience) in Physics—The Clerk to the Governors, Mid-Essex Technical College and School of Art, Market Road, Chelmsford.

Chemist (with a first- or second-class honours degree in chemistry and at least two years research experience, either postgraduate or in industry), to undertake original research on the chemical constitution of coal and the basic chemistry of its use, in co-operation with a team of workers at present engaged in studying these problems—The Assistant Secretary, Ref. C.16, British Coal Utilization Research Organization, Randalls Road, Leatherhead, Surrey.

Departmental Demonstrator in Engineering Science for duties which will include both lecturing and undergraduate instruction in the laboratories—Prof. A. Thom, Department of Engineering Science, 19 Parks Road, Oxford.

Laboratory Technician (with bacteriological or virological experience) for Virus Research—The Medical Superintendent, Harvard Hospital, Salisbury, Wilts.

Master to teach Mathematics—The Head Master, Cheltenham Grammar School, Cheltenham.

Physical Chemist (with at least a first- or second-class honours degree in chemistry or chemical engineering, and many years experience), to lead a team consisting of chemists, chemical engineers and engineers carrying out development in a new field of inorganic materials technology—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting Ref. 1068/34.

Physicists (Scientific Officer, Experimental Officer or Assistant Experimental Officer grade), at Ministry of Supply Research and Development Establishments, near Farnborough, Hants; Malvern, Worcs; Salisbury, Wilts; and Sevenoaks, Kent, for work on guided missiles, aircraft and aircraft equipment, gas turbines, instrumentation or electronic devices—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.77/6A/BN.

Principal Scientific Officer (Fuel Technology and Chemical Engineering) (with at least a second-class honours university degree or equivalent professional qualifications, and experience in chemical engineering and fuel technology), with the East African Industrial Research Organization, Nairobi, Kenya, to undertake research and development in industrial technology, including processing of crop products, and to study fuel economy in various industries, and generally provide technical assistance to these—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.195/463/02.

Research Fellow (with a good honours degree or equivalent and some specialized experience of paint and/or building materials, and preferably some research experience) to investigate problems of use and behaviour of paint on buildings in tropical climates—Colonial Office, Research Department (S.608), Sanctuary Buildings, Great Smith Street, London, S.W.1.

Scientific Officers (with a first- or second-class honours degree or equivalent in electrical engineering, physics or mathematics) at the National Physical Laboratory, Teddington, Middlesex, for work on control mechanisms and electronics, principally the development of digital computers—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting D.90/6A.

Scientific/Senior Scientific Officer (with an honours degree in engineering or physics, and preferably with experience of research and experimental work), at a Ministry of Fuel and Power peat experimental station near Falkirk, Stirlingshire, for work on mechanical winning, pressure dewatering and drying of peat for use in power stations—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W 1, quoting C.956/5A.

Senior Assistant (Scientific) (with a knowledge of pulse techniques, high speed oscillography and methods of measuring small time intervals) at the Atomic Weapons Research Establishment, Aldermaston, for development of electronic timing and control equipment for routine testing of explosive items—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting Ref. A 551/34.

Senior Scientific or Scientific Officers (with a first- or second-class honours degree or equivalent in mathematics, physics or engineering) at the Ministry of Supply London Headquarters, for co-ordination of aerodynamic research at research establishments, and of research projects at aircraft firms—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.78/6A/BN.

Technical Officer (with a degree in botany or agriculture or equivalent qualifications and a knowledge of herbage strains, and preferably some practical experience in seed production) in the Herbage Section of the Seed Production Branch—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge

DIFCO

DETECTION OF THE GONOCOCCUS

The superiority of the cultural method over the usual microscopic technique for detection of gonococcal infections has repeatedly been demonstrated. The cultural method is especially indicated in chronic and treated cases and for determining the release of patients. The use of the following standardized materials has simplified the diagnosis of gonorrhoea by the cultural method.

- Bacto-G C Medium Base
- Bacto-Proteose No. 3 Agar
- Bacto-Dextrose Starch Agar
- Bacto-Phenol Red Media
- Bacto-Supplement A
- Bacto-Supplement B
- Bacto-Hemoglobin
- Proteose Peptone No. 3

TECHNICAL EDUCATION IN BRITAIN

SUPPORTED by some notes on technical man-power in the United States, Soviet Russia and Western Europe, and by a report on 'sandwich' training and education from the National Advisory Council on Education for Industry and Commerce, the Government has issued, on the last day possible to redeem its promise, a White Paper on Technical Education*. Apart from the fact that it excludes agricultural education, it is an admirable tract for the times; and the programme it sets forth is accompanied by accounts of technical education in England and Wales and in Scotland which are both readable and put technical education in reasonable perspective in the education system of the country as a whole. The programme includes some sound proposals, but although the White Paper bears evidence of the haste with which it was produced, it is difficult to discover in the plan now outlined any evidence of deep thinking or new initiative that would account for the long delay. On the face of it, this programme could well have been enunciated when the statement rejecting the idea of a technological university was made in December 1954.

As it is, although the way has been cleared to some extent by the further statements made last year regarding technology at the universities and the expansion of the Imperial College of Science and Technology, the piecemeal approach persists. We have still to wait for the universities to produce their plans for technological education for the quinquennium 1957–62, and until these plans have appeared it is impossible to judge how far the £100 million it is now proposed to spend on technical education will go towards fulfilling the Prime Minister's declared intention of January 18 of making good the present shortage of scientists, engineers and technicians.

What needs to be remembered, in the first place, is that the measures now proposed are measures to meet a crisis: they are ameliorative rather than preventive. The White Paper contains fresh evidence of how this sustained piecemeal approach frustrates any effective policy and places obstacles in the way of those who seek to evolve a rational system of education for Great Britain which would eliminate the recurrent difficulties; and not only afford full opportunity to talent of every kind, but also ensure that at every stage facilities exist for bringing out the full potential energy of the population and encouraging its interests in directions that are most desirable socially. There is little in the White Paper to warrant confidence that the nation will get the maximum value from the expenditure now proposed. Indeed, apart from anything else, too much depends on factors outside the Government's control: on the extent to which the co-operation rightly required from the public—from parents and teachers, from the local authorities, from the universities and from industry—is in fact achieved. Government by exhortation has its points, but it has its weaknesses also.

To the extent to which the policy outlined in the White Paper depends on public understanding and support, the Government has been wise to cast it largely in the form of a tract for the times, and to take advantage of the interest which has been aroused of late by comparisons with scientific and technical man-power in the United States and in Soviet Russia such as Lord Simon, Dr. A. V. Bowden, Sir Francis Simon and Sir Solly Zuckerman, and Mr. Nicholas de Witt in his recent book on Soviet professional man-power, have made. Nevertheless, while the White Paper deprecates excessive attention to such comparisons and stresses the circumstances which determine the particular needs of Britain for trained man-power, the magnitude of those needs is not appraised. We are given estimates of the potential supply and the generalized statement that as many as six or seven technicians may be required for one scientist or technologist, but no estimate of the probable demand. It is assumed that useful occupations can be found for all who can be trained.

That may well be true within the proviso that we give sufficient attention, as the White Paper recognizes, to encouraging adaptability and finding a place in technical studies for liberal education. Technical education, it insists, must not be too vocational or confined to one skill or trade; and more attention must be given to the teaching of good plain English, if only to facilitate bridging the gaps that separate experts in different specialized subjects from the general public as well as from one another. Nevertheless, if we are to win the support of parents, they must be convinced that there is every reasonable prospect of a satisfying career open to the boys and girls who enter technical colleges or colleges of technology.

That, of course, is one of the first conditions of success in the first and most difficult step, namely, raising the number of entrants to advanced courses in technology and securing as corollary a sharp reduction in the number of early leavers. It is, moreover, in such qualitative proposals that the White Paper offers most hope of advance, for those proposals could contribute much to the success of a more fundamental and considered long-term policy such as we have yet to see. It attacks, for example, the excessive reliance on evening classes, which are more wasteful alike of students and of staff than day classes, and proposes to double the numbers released for employers for part-time day courses. Similarly, it comes out strongly in favour of the 'sandwich' courses, which Dr. P. F. R. Venables in his recent book regarded as one of the most encouraging signs of the times; and it recognizes the reserve of talent available in modern secondary schools, which is probably best tapped by the technical colleges, as well as that available in girls schools, if girls can be induced to seize the opportunities for a congenial career which science and technology can offer.

---

* Technical Education. Pp. 44 (Cmd. 9703.) (London: H.M. Stationery Office, 1956.) 1s 6d. net.

Beyond pointing to this reserve of talent and stressing the need for rousing the interest and co-operation of parents, the White Paper makes no practical suggestions as to how this is to be achieved. It does, however, make the important proposal that students proposing to attend courses leading to a technological award shall be eligible for Technical State Scholarships, and the number of these Scholarships, which are already available to those employed in industry to enable students of outstanding ability to pursue honours degree courses at universities or elsewhere, will be raised as the capacity of such advanced courses at technical colleges is increased from the present 9,500 to the proposed 15,000. Moreover, to encourage boys and girls to enter such courses straight from school, it is proposed in future to allow State Scholarships awarded on the results of the General Certificate of Education examinations to be held for courses leading to a technological award as well as for honours courses at universities.

Much here is left to the co-operation of the local education authorities in assisting such students with major awards at rates equivalent to those paid to university students, and to the assistance of industry in paying the fees of students attending advanced sandwich courses. The Government is clearly wise to seek such co-operation, but it should be fostered and stimulated as sedulously as possible. More thought might well be given to ways and means than appears on the surface in the White Paper.

It is here, however, that the piecemeal approach is at a disadvantage, and it is with the provision made for expanding the number of full-time or sandwich courses in advanced technology that doubts enter as to the effectiveness of the Government's proposals. The Government proposes that the bulk of the full-time or sandwich courses should be carried on in colleges which concentrate on advanced courses at technological level; and for this purpose it is advocated that, within the five years over which the new grant of £70 million for building and £15 million for equipment is to be expended, the twenty-four colleges at present receiving 75 per cent grant for certain of their advanced work shall divest themselves of work below the advanced level and develop speedily into colleges of advanced technology. It is also contemplated that a few other colleges may qualify for 75 per cent grant, and it appears to be implied in the White Paper that these also may develop into colleges of advanced technology. Indeed, the Minister of Education was pressed specifically in the House of Commons on March 8 to make further provision in the West Riding of Yorkshire and on Tees-side.

It would not appear that by the term 'college of advanced technology' the Government has in mind anything like the Manchester College of Technology or the Royal Technical College, Glasgow; but beyond reference to the fact that the former institution will come under the ægis of the University Grants Committee, there is no indication as to what the distinction is. Moreover, the belief that the Government has not even yet grasped the implications of its proposals is further encouraged by the statement that the part-time advanced courses provided in some one hundred and fifty local colleges conveniently placed for the students and part-time staff who work in industry make, and will be expected to continue to make, a vital contribution to the total output of technologists. In spite of sound definitions of technologists and technicians given in the White Paper, there is little indication that the distinction has been given due weight in the Government's proposals, or that the results of the inquiry into scientific and technical man-power now being carried out by the Technical and Scientific Technical Register of the Ministry of Labour and National Service are likely to be given due weight when they are published later this year. Meanwhile, Sir David Eccles suggested tentatively on March 8 that roughly one-fifth of the £70 million would be required for colleges of advanced technology or for branch colleges to relieve them of less advanced work.

It is not simply that, in the absence of the facts which such an inquiry alone can provide, no sound apportionment of resources of Britain between technical and technological education can be made. Equally important is the question whether we have the resources to establish twenty or thirty colleges of technology, and whether in attempting to do so we may not instead so disperse our resources that most of these colleges will have neither the independence, the status nor the financial resources to enable them to attract staff of the requisite calibre, or students to provide the country with a sound investment from the resources applied. The White Paper admits that regional planning must play a larger part in future if there is to be reasonable economy in buildings and staff, but the Government largely closes its eyes to the inevitable effect on the administration of such colleges.

That the administration of a college of technology is possible in association with local government is shown by the development of the Manchester College of Technology. That example, however, shows the way in which autonomy and civic pride and interest can be reconciled; but it is to be feared that in its reliance on local authorities in this matter the Government is guilty of wishful thinking, just as it is over the National Council for Technological Awards. The folly of refusing to face the facts was clearly shown by Dr. Venables in commenting on regional colleges in his recent book, and the White Paper advances no evidence to suggest that any improvement is to be expected short of placing colleges of technology like the Manchester College of Technology either under the University Grants Committee or, perhaps better still, under a Technological Grants Committee of similar status and powers and possibly charged also with the supervision of technical education in general. Until this is done, the colleges of technology in Britain are unlikely to enjoy either academic autonomy or the status which will enable them to attract teaching staff of high calibre; and even if they have a sufficiently secure financial basis for long-term planning, the local authorities responsible for the college are likely to be subject to an unreasonable strain of loyalties. Local bodies should not be expected to finance national or even wide regional purposes out of local funds; indeed, as Alderman Barber, chairman of the Bradford Education Committee, has remarked, it is impossible for a local authority, however generous or determined, to ignore the limitations imposed by the amount of rates it can raise.

Dr. Venables's restrained but reasoned argument has been ignored by the Government; and little confidence will be entertained elsewhere in the outcome of the Minister of Education's attempt to induce local authorities generally to establish strong governing bodies widely representative of industry and with powers to spend within the needs of annual estimates approved by the authority. Even if the Ministry of Education possessed the requisite experience, the Minister is not meeting Dr. Venables's point as to the need for a quinquennial or similarly secure long-term basis of planning such as the University Grants Committee supplies—a factor particularly important if the colleges are to develop, as the White Paper suggests, a substantial amount of research, especially research sponsored by industry, or to initiate post-graduate studies. The importance of academic autonomy and status is sadly under-rated by the Government. To bring the colleges of technology under the ægis of a national body of the character of the University Grants Committee, if not that body itself, would do more in a few months to give them the standing and independence which would attract first-class teaching staff than the new award to be given by the National Council for Technological Awards is likely to achieve in many years. Such merits as the latter proposal may possess are long-term in character, and what is needed is, as the Government protests, immediate, if not emergency, action.

But there is another respect in which the White Paper treats the staff issue too lightly. To establish a Technological Grants Committee or to bring the colleges of technology under the University Grants Committee would enable the colleges to compete on more even terms for highly qualified staff and would be far more effective than improved salaries alone. To prune more severely in accordance with material resources the number of colleges to be upgraded to perhaps a dozen or so would also assist, and at the same time ease the difficulty with local government which appears to cause the Government so much concern. Neither step, however, would entirely remove the difficulty over the number of teachers.

This is the weakest spot in the Government's proposals in the White Paper. It is admitted that many more teachers will be required to achieve the objectives set out in the White Paper, and the importance of quality is also recognized. Nevertheless, there is no appreciation that different types of teachers may be required for the technical colleges and technical schools and for the colleges of technology. The existing shortage of science teachers is ignored, and the Government merely expresses the hope that industry will be ready "to release yet more of its employees for part-time teaching during the day, so that its apprentices may be given the more thorough grounding which modern conditions require"; and that by offering the right conditions of service for technical college staff, local education authorities will be able to attract a reasonable share of the available technical man-power.

This is not a policy, and though the White Paper's proposals cannot be fully judged until it is known later in the year what the universities propose to do for technological education over the next quinquennium, it is hard to believe that the proposals now advanced will prove effective in the absence of the measures suggested in regard to academic autonomy and continuity. Pending the results of the inquiry now in progress under the Minister of Labour and National Service, it is to be hoped that the development of further colleges of advanced technology in Britain will proceed with caution, and that more attention will be given to the needs of the technicians. Meanwhile, however, if the organization of sandwich courses is vigorously implemented and also the new proposals for financial aid to students of technology, and if effective measures are taken to secure greater co-operation from industry and the support and understanding of parents, particularly a wider appreciation of the opportunities of careers in technology for girls, substantial steps will have been taken towards better adaptation of at least the functioning of the whole educational system of Britain to meet the nation's needs to-day. But there should also be proceeding a review of the educational system as a whole, qualitatively as well as quantitatively, in which a much more fundamental regard than is apparent in the White Paper is shown, not merely to the nation's needs for trained man-power but also to the purpose of education, to the relations at the different levels and equally to the needs of youth as individuals and citizens, no less than as scientists or technologists, as teachers, as technicians or as craftsmen.

RESEARCH REACTORS IN THE UNITED STATES

Research Reactors

(Selected Reference Material on Atomic Energy.) Prepared by the United States Atomic Energy Commission. Pp. xii+442. (London: McGraw-Hill Publishing Co., Ltd., 1955.) 49*s*.

THE United States Atomic Energy Commission prepared for the Geneva International Conference on the Peaceful Uses of Atomic Energy six volumes summarizing United States work in various fields of atomic energy, of which this handsomely produced book is one. It describes eight of the principal types of research reactors used in the United States, ranging from a 1-W. water-boiler type of reactor to the 30-MW. material-testing reactor in the Idaho desert. Each of the reactors is described, with many detailed drawings and photographs of the reactor and its components. The distribution of neutron flux is given in detail. Very full details are also given of start-up and operating procedure. Particularly full details are given of the design calculations of the M.T.R. (40-MW.) reactor.

Costs of the various reactors are given, and these vary from 250,000 dollars for a simple swimming-pool reactor to 25 million dollars for the Brookhaven graphite reactor. A detailed analysis of costs for some reactors is provided, and a warning is given that the actual cost depends very much on what buildings and laboratories are associated with the reactor. With this wealth of detail the prospective user may have some difficulty in deciding which type to adopt. In many cases financial consideration will rule out the high-powered more expensive reactors. A reactor in the 10-MW. class will cost £2–4 million and can cost up to £500,000 a year to operate. University users will be limited by cost to reactors of not more than 1 MW. of power. In this class the 1-MW. light-water reactor will probably provide the best compromise between high neutron intensity and moderate price. Its neutron flux of 10^{13} neutrons/sq. cm./sec. makes possible a very wide range of experiments. A flux of 10^{12} is generally considered to be too low for many experimental applications.

The solid-fuel research reactors require a fuel charge of 3–4 kgm. of uranium-235, and this is usually formed into a uranium–aluminium alloy and sheathed in aluminium. The United States has made agreements with many countries to supply research reactors together with 6 kgm. of enriched fuel, the fuel being lent at interest-rates of 4 per cent. Britain is supplying enriched fuel to India, Australia, France and Denmark for research reactors.

Research reactors have become an essential tool of any serious programme for the development of nuclear power, and Britain will soon be equipped with six such reactors, five at Harwell and one at Dounreay. Their use in university research is being seriously discussed at present, and this volume will help those members of university staffs who are concerned.

J. D. Cockcroft

A NEW APPROACH TO BIOSYNTHESIS

Studies of Biosynthesis in Escherichia coli

By Richard B. Roberts, Philip H. Abelson, Dean B. Cowie, Ellis T. Bolton and Roy J. Britten. Pp. xiv+521. (Publication No. 607.) (Washington, D.C.: Carnegie Institution of Washington, 1955.) 2.50 dollars (paper bound); 3 dollars (cloth bound).

FIVE years ago a group of nuclear physicists at the Department of Terrestrial Magnetism of the Carnegie Institution of Washington began an investigation of biosynthetic processes in micro-organisms, making use of radioactive isotopes. This monograph is "a report of research" and represents the achievements to date of these men and their associates. It is an ambitious piece of work: what is presented is a fairly thorough description of the pathways by which carbon atoms from glucose become incorporated into the components of proteins, nucleic acids and lipids of *Escherichia coli* when this organism grows in a simple synthetic medium. A detailed account of the intermediate steps in amino-acid and purine and pyrimidine synthesis is not attempted, but the broad outline of a flow sheet for carbon is sketched both qualitatively and quantitatively. Many of the individual pathways had previously been studied in a range of different organisms under a variety of conditions, but here begins the first attempt to co-ordinate and integrate them in a map of the total synthesis of a bacterium.

The design of the experiments is modest—*Escherichia coli*, growing exponentially in a glucose–ammonia–salts medium, is presented with a tracer labelled with carbon-14 (carbon dioxide, acetate, an amino-acid, or glucose variously labelled) and perhaps some other unlabelled substrate. The pattern of incorporation of radioactivity in amino-acids, nucleotides, etc., is then determined both qualitatively and quantitatively after at least one further generation of growth. From the results of such experiments it is shown, for example, that amino-acids fall into biosynthetic families: serine being precursor to cysteine and glycine; pyruvic acid to alanine, valine and leucine; glutamic acid to proline and arginine; aspartic acid to threonine, methionine, *iso*leucine, lysine and diaminopimelic acid. Similar relationships with minor modifications are found in the yeast, *Torulopsis utilis*, and the mould, *Neurospora crassa*. Histidine and the aromatic amino-acids are not dealt with.

The early chapters are devoted to detailed accounts of experimental methods, fractionation and chromatographic procedures, production of randomly labelled amino-acids by growth of *Chlorella* in carbon-14 dioxide, and permeability studies. Then come chapters on the results of experiments with specific tracers, the variations caused by adaptation to energy sources other than glucose, and the extra-cellular products of metabolism.

The pathways of amino-acid and nucleotide formation are discussed in the light of the accumulated data, and it is suggested that the Krebs's tricarboxylic acid cycle is involved in the production of intermediates for synthesis rather than for terminal oxidation. A long chapter follows on sulphur metabolism and the roles of glutathione, which contains about one-quarter of the sulphur of *Escherichia coli*, and an alcohol-soluble protein fraction which amounts to about one-sixth of the total protein.

The method of 'isotope competition' is critically examined in the penultimate chapter. This method, which depends on the preferential utilization of exogenously supplied intermediates as compared with endogenously synthesized substances, has been used to gain information about biosynthetic sequences. Thus, when randomly labelled glucose is the major carbon source for growth of *Escherichia coli*, the addition of unlabelled glycine suppresses the appearance of radioactivity in the protein glycine. Addition of unlabelled serine, on the other hand, prevents the appearance of radioactivity in both serine and glycine, indicating that serine is precursor to glycine but not vice versa. Isotope competition has been successfully exploited in the case of *E. coli*, but the method is not invariably applicable; and it is pointed out that its effectiveness is in some cases due to suppression of synthesis by the addition of an intermediate, whereas in others synthesis continues at an unchanged rate but the endogenously produced material is 'swamped' by the exogenous and most of it can (if isotopically labelled) be found in the medium.

The last chapter attempts a quantitative description of the flow of carbon from glucose to cellular components and waste products. One of the tantalizing findings of this work, which in the main so beautifully balances the carbon account, atom by atom, is that the route of formation of 70 per cent of the total carbon dioxide and 90 per cent of the carbon dioxide derived from C-1 of glucose is unknown. It is suggested that the net output of carbon dioxide from the tricarboxylic acid cycle is less than 3 per cent of the observed production, so that some alternative mechanism must exist for the degradation of glucose to carbon dioxide. Recent findings in other laboratories indicate that a transketolase–transaldolase cycle might be involved.

Thus the report ends with new questions being posed—which is just as it should be. This is an essentially personal account, with five authors whose different styles are apparent but not disconcertingly so. Some readers will challenge the conclusion that the micro-organisms used are freely permeable to ions and small molecules, including hexose phosphates and glutathione, and others will question whether the time is ripe for application, as it were, of Kirchhoff's laws to living organisms. There is little discussion of related findings by other workers using other techniques, but (perhaps as compensation) there is a classified bibliography of well over a thousand post-1940 papers on the biochemistry of *Escherichia coli* and other topics relevant to the text. Two useful appendixes on the kinetics of incorporation and dilution are also included. There is a wealth of illustration, including some thirty full-page reproductions of radioautographs. The text, which is reproduced by a lithographic process, is easy to read and the figures are well drawn, but some, in the chapter on sulphur metabolism, have inadequate legends. The few misprints are mainly confined to tables.

The Carnegie Institution of Washington was founded "to encourage, in the broadest and most liberal manner, investigation, research, and discovery . . .". It is well-served by a director such as Dr. Merle A. Tuve, who enthusiastically supports a group of his physicists when they break away into microbiology and when they justify themselves, as in this first major progress report, by writing of "the intense personal pleasure that has come to us in this research". KENNETH MCQUILLEN

THE HAUNTING OF BORLEY RECTORY

The Haunting of Borley Rectory

By Eric J. Dingwall, Kathleen M. Goldney and Trevor H. Hall. Pp. xiv+181+5 plates. (London: Gerald Duckworth and Co., Ltd., 1956. Published under the auspices of the Society of Psychical Research.) 16*s*. net.

THIS account of the evidence for abnormal happenings in what the late Harry Price described as "the most haunted house in England" well maintains the tradition of the Society for Psychical Research for honest and cautious study of alleged parapsychological phenomena. A heavy task was undertaken at the invitation of the Society by three trained investigators. Their story is at times as interesting as a detective novel; it reveals queer actions of some very curious people; it leaves very little to be explained of the actual haunt itself and a good deal to be puzzled over in the motives, actions and reactions of the people principally concerned. The general conclusion is that credulity, malobservation, trickery and fraud account for the great bulk of the recorded evidence.

Criticism has been directed against the Society for Psychical Research for having so long delayed an inquiry into Borley Rectory. The relevant facts are these. The case first achieved more than local notoriety in June 1929, when the incumbent, the Rev. Eric Smith, wrote to the editor of the *Daily Mirror* asking for advice as to whom to consult as to the best method of clearing the rectory of its bad local reputation as a haunted house. The results were visits from a reporter and from Harry Price. Articles published in the paper brought crowds of sightseers to the rectory; the situation developed rapidly and was soon out of control. Serious investigation became impracticable, and in any event Harry Price had taken over the case. Two visits were actually paid by Lord Charles Hope, later a member of the Society's council, in July 1929; he came away with the view that the phenomena were produced by normal means and with the suspicion that Harry Price was responsible for some of them. Public interest was maintained, however, by Harry Price sending a rota of (untrained) investigators to report on the haunting and by his two books on Borley Rectory. The Society took up the challenge of this continued publicity in 1949 after Mrs. Eric Smith had written to the *Daily Mail* to express her disbelief in the haunting of the rectory. Price had died in 1948 but his literary executor, Paul Tabori, gave facilities to the investigators to examine his files and correspondence in the Harry Price library. A large part of the case against Harry Price comes from his own writings and papers. Doubts about the genuineness of the phenomena produced in the presence of Mrs. Foyster, wife of a later incumbent of Borley, were also expressed by Price and are strongly underlined in this report.

The destruction of the rectory by fire in 1939 has not ended the story of the haunt, nor the popular interest in Borley. The writers of this book give good reasons why the vague stories of its early haunting and also the more recent accounts need not be taken seriously, and why their report can fairly be taken as "The End of Borley Rectory". The tragedy is that it brings discredit to the name of one who had done so much to bring psychical research to the notice of the general public.

F. J. M. STRATTON

GENETIC RECOMBINATION

Symposium on Genetic Recombination

Given at the Research Conference for Biology and Medicine of the Atomic Energy Commission, Oak Ridge, Tennessee, April 19–21, 1954. (Reprinted from *Journal of Cellular and Comparative Physiology*, Vol. 45, Supplement 2, May 1955.) Pp. vii+321. (Philadelphia, Pa.: Wistar Institute of Anatomy and Biology, 1955.) n.p.

IN the late 'twenties and early 'thirties there was great interest among geneticists and cytologists in attempts to understand the mechanism by which genetic crossing-over takes place. It was believed by many that this would prove a profitable way to attack the problem of gene and chromosome structure. Although several useful working hypotheses were formulated, these hopes were not realized. In fact, no widely accepted hypothesis consistent with all the facts known about crossing-over in higher forms has yet been proposed. Perhaps one of the most ingenious of the earlier suggestions, especially in the light of the recent proposal of Watson and Crick as to how macromolecules of deoxyribonucleic acid might reproduce, was the one presented by the late John Belling.

In recent years a marked revival of interest in the crossing-over approach has been stimulated by a series of inter-related developments in genetics. Among these is the large body of evidence that pneumococcal transforming principles are deoxyribonucleic acid, the demonstration that genetic information in bacterial viruses is transmitted in the form of this macromolecule, and the realization that the Watson–Crick double helix structure of deoxynucleic acid might well explain how genetic information is replicated.

A symposium on "Genetic Recombination" was held in the United States during April 19–21, 1954, at the Oak Ridge National Laboratory, and this volume consists of sixteen papers summarizing what had been accomplished at the time of that meeting. The subjects dealt with include pneumococcal transformations, transduction and other recombination mechanisms in bacteria; crossing-over in fungi, algæ, higher plants and higher animals; and, finally, the oxygen effect on chromosome aberrations in higher forms. The symposium dealt with, but did not finally answer, the important question of whether the recombination mechanisms in bacterial viruses and higher plants and animals are fundamentally the same. Chromosomes of the latter contain protein as well as deoxyribonucleic acid and are many orders of magnitude larger than the deoxyribonucleic acid helices of viruses. In addition, in a number of higher forms it is known that, in contrast to recombination in bacterial viruses, a single cross-over produces complementary recombination structures. It may therefore be too much to hope that a single mechanism will account for both processes.

Progress in understanding genetic recombination is at present being made so rapidly and requires so much specialized knowledge for its full appreciation that it is difficult for the general geneticist or biologist to keep up to date. Reports of symposia such as the Oak Ridge one are a great help in this respect.

G. W. Beadle

THE NATIONAL GALLERY, LONDON

The National Gallery 1938–54

Pp. 124+20 plates. (London: National Gallery, 1955.) 12*s*. 6*d*. net.

In 1938 the National Gallery, presumably for reasons of economy, ceased to publish a Director's annual report. That practice is now to start again and, in the meantime, the Trustees have issued a most welcome comprehensive survey of the years 1938–54. This is a model of lucid statement. It not only gives a detailed account of those things one expects to hear about—the evacuation of the collection to Manod quarry at the beginning of the Second World War, the acquisitions during the period under review, and the development of a Scientific Department and a Conservation Department—but, in addition, it records activities which annual reports usually take for granted. It explains, for example, the duties of the senior members of the staff—the keepers and assistant keepers—and gives the public some insight into the extraordinarily complicated work involved in compiling catalogues of the standard of those already produced by Mr. Martin Davies and Mr. Neil MacLaren. Before the War a catalogue of the whole collection was available, but the information it contained was too slight to be of very much use to scholars. The detailed catalogues of the British, French, Spanish, Early Netherlandish and Earlier Italian Schools issued during and after the War have, however, set a standard of scholarship which is a model to the galleries of the world. A new general catalogue, which, one hopes, will be of a more lively character than the pre-war edition, is also in preparation.

The report is not only comprehensive, it is also honest. It records in detail the treatment given to every picture that has been restored and cleaned since the Conservation Department was set up in 1947, and reveals the extent to which scientific examination can solve problems which the eye alone can only guess at. The cleaning of Piero della Francesca's "Nativity" has, for example, shown quite certainly that the thin condition of parts of this picture is due not to its being unfinished, as has often been suggested, but to drastic overcleaning in the past. Again, examination of Van Dyck's "Charles I on Horseback" showed that, when it was first relined, the canvas had been cut in two because of its great size. The work of removing previous relinings and restoring the original canvas involved the construction of a special table and the placing of an awning over the studio roof which had not been repaired since the War.

The question of war damage and its repair is one of the two disquieting subjects in the report, the other being the more serious one of lack of funds. Bomb damage put the west wing of the building out of action, and it was decided to instal as soon as possible a badly needed air-conditioning plant which would serve the rooms in this wing as they were re-opened. The plant was installed after delay, and the rooms are gradually coming into use; but even by the end of 1956, eleven years after the end of the War, parts of this block of the gallery will still not be available for the exhibition of pictures. This is the more serious when one realizes that since 1938 the collection has been increased by about a hundred and eighty pictures. A number of these have been transferred to the Tate Gallery, but there have also been transfers to the National Gallery from the Tate. Rebuilding does, however, progress, if only slowly. The problem of the lack of funds available for purchases is more urgent. A national collection, however large, is never complete. There will always be certain pictures which, if they come on the market, should be bought for the National Gallery rather than any other. But the annual government grant to-day, £10,500, stands only a few hundreds higher than it did in 1880. The Gallery has an additional income of about £10,000 from endowments, but with only £20,000 a year available, it is quite unable to compete for masterpieces unless Parliament votes a special grant-in-aid. The need for a very much larger annual grant is undeniable.

This report is not written for the profession only. It is written for all those persons who care for fine pictures, and it should be read by them. It can be strongly recommended.

K. J. Garlick

Cotton Growing Problems

By Prof. Basil G. Christidis and George J. Harrison. Pp. vii+633. (London: McGraw-Hill Publishing Co., Ltd., 1955.) 73*s*.

FIFTY years ago there was not much background of scientific knowledge about cotton in the field, but few crops to-day are better known, so that the biggest problem facing the cotton-grower is how to write a concise account of our garnered knowledge and to expose the gaps in it. The natural starting-point for a grower is the seed, but the first half of this book deals with varieties, crop rotation and soil fertility; then the seed appears, to be followed up through its planting and cultivation.

This lack of balance is also evident in the use of references; there is little discrimination between major studies, minor observations and tertiary oddments.

There are large omissions, notably in the chapter on irrigation, which does not refer to the two volumes of Willcocks and Craig, nor even to my own recent book. The remarkable sixteen-year set of field experiments by D. S. Gracie is not cited until long after Part 3, on fertilization, has been concluded, and then in a line only. There is no hint that the cotton hair is built of growth-rings, that the cotton plant has a root, or that the whole crop of all varieties grown in Egypt is derived and maintained from 'individual selection'. The bibliography includes more than a thousand entries, in spite of omissions, but is difficult to use because it is split into eight separate groups, one for each part of the book, covering sixty-two scattered pages.

Many observations from the Greek cotton research station at Sindos by Prof. B. G. Christidis are quoted, and are evidently comprehensive. I wish that Prof. Christidis could have dealt with this, his first-hand knowledge, in more detail; for the differences of soil and climate found under conditions in Greece can be most illuminating, and a book thus severely localized in its material would have been more generally suggestive in formulating the problems of cotton-growing.

W. LAWRENCE BALLS

The Analysis of Drugs and Chemicals

By Dr. Norman Evers and Wilfred Smith. Pp. xii+546. (London: Charles Griffin and Co., Ltd., 1955.) 60*s*. net.

THE forerunner of this book, by Evers and Elsdon, appeared more than twenty-five years ago and acquired a deserved reputation as a useful book to those engaged in the field covered by the title. Since that time, many new drugs and chemicals have come into general use, only a proportion of which have been included in the "British Pharmacopœia", or the "British Pharmaceutical Codex". The present volume deals with the official drugs and a number of the more important unofficial ones, together with those chemicals which find application in pharmacy. It is in the same form as its predecessor, but has been completely rewritten.

There is no clear-cut classification of the heterogeneous materials used in medicine, and the distinction between drugs and chemicals can only be arbitrary. Nevertheless, some sort of grouping is necessary and this has been appropriately done under the following headings: inorganic chemicals; organic chemicals; natural compounds and their derivatives; fixed oils, fats, waxes and soaps; volatile oils; crude drugs; miscellaneous pharmaceutical materials; and galenicals and other pharmaceutical preparations. These groups are preceded by chapters on general analytical methods, and followed by one on the use of statistics in chemical analysis and by several useful appendixes.

The book is intended to supplement the "British Pharmacopœia" and the "British Pharmaceutical Codex"; it must be used in conjunction with these volumes, since it is rarely indicated whether the substances mentioned, or the tests to be applied, are official or not. When so used, it should prove useful to the advanced student and to those engaged in the examination of named substances. It will be of only limited value to those concerned with unknown substances, for example, the toxicologist; the "of" in the title must not be read as including "for".

J. R. NICHOLLS

College Chemistry

An Introductory Textbook of General Chemistry. By Prof. Linus Pauling. Second edition. (Series of Chemistry Texts.) Pp. xii+685. (San Francisco: W. H. Freeman and Company; London: Bailey Bros. and Swinfen, Ltd., 1955.) 6 dollars; 51*s*.

FOR the new edition of this book Prof. Linus Pauling has revised throughout both the text and illustrations. In the first part the facts, concepts and theories are presented more gradually and factually, and the sequence of chapters altered to provide a more systematic arrangement. Each of the six parts has an introduction describing the chapters in it and explaining why each topic is introduced in the given order. The amount of organic chemistry is increased, and at the end there are two new chapters on chemical substances related to living organisms and one on nuclear chemistry.

Chapter 3 on the electron and nuclei of atoms, in which the subjects are treated historically, is clear and easily understandable. It is followed by one on the periodic law treated on a factual basis, which is then explained on the basis of atomic structure. The descriptions of the preparation and properties of elements and compounds are related as far as possible to atomic and molecular structure. The subject of valency is particularly fully and carefully treated, and much attention is given to the geometry of molecules. The sections on physical chemistry are clear and are introduced in appropriate places. Much use is made of the historical approach throughout the book.

There is no doubt that the book has been greatly improved in the new edition. Many teachers who desire to introduce modern aspects of theoretical chemistry into their courses will find how this can be done without sacrificing fundamental chemistry by a study of Prof. Pauling's thoughtful book.

Rational Approach to Chemical Principles

By Dr. John A. Cranston. Second edition. Pp. xii+231. (London and Glasgow: Blackie and Son, Ltd., 1955.) 10*s*. 6*d*. net.

THIS small book, now in its second edition, evidently fills a need in giving a brief account of the background of physical chemistry of about intermediate degree examination standard. There may be some doubt as to whether it is really rational to introduce quantum numbers before the simple gas equation; but if students are prepared to swallow whole this preliminary summary of atomic structure, the rest is plain sailing. In the present edition, the author has included many more numerical examples in physical chemistry, which no doubt will be found useful, and the book will continue to serve a modest but useful purpose.

J. A. V. B.

THE INTERNATIONAL GEOPHYSICAL YEAR

GEOPHYSICAL STATION AT COATS LAND, ANTARCTICA

By J. M. WORDIE, C.B.E.

THE station recently established by the Royal Society in Coats Land in the Falkland Islands Dependencies will be one of the most comprehensive among the many others now being set up in the Antarctic for the International Geophysical Year. The different sections of the programme are being given full opportunity to develop in whatever direction seems the most promising. Moreover, the station, which is a large one, has been set up not only in an important area, but also in favourable local conditions.

It should be noted, however, that this is not the only British station in Antarctica. There is already a well-equipped geophysical station at the Argentine Islands on the west coast of Graham Land in lat. 65° 15′ S., long. 64° 16′ W. Geophysical work in the Dependencies began in 1948 when ionospheric observations were first made at Port Lockroy. Later, the Argentine Islands base, about twenty miles farther south, was developed as more suitable for geomagnetic and upper-air work in general, and this station is now dealing with solar radiation, ozone observations, and a geomagnetic programme, which began on January 1, 1956. Ionosphere observations, however, continue at Port Lockroy. These two places in combination form an important link in the line of International Geophysical Year stations situated near the 70°–80° W. meridian line. Both are organized and manned by the Falkland Islands Dependencies Survey under the authority of H.E. the Governor, Mr. O. R. Arthur, who has continued the policy of the previous Governor, Sir Miles Clifford.

Apart from this, there will also be subordinate International Geophysical Year stations, mainly for meteorological and glaciological purposes, at Marguerite Bay in South Graham Land; at King George Island in the South Shetlands; and at South Georgia.

The Royal Society's station on Coats Land carries out the suggestion made at the second meeting of the Special Committee for the International Geophysical Year in Rome in September 1954, that a station should be set up on the Antarctic continent in the important area of the inner Weddell Sea. It was not until a year later, however, that a final decision was made by the Society. The chief difficulty had been doubt about navigation conditions in the Weddell Sea and in the waters off Coats Land, and these doubts were not resolved until the beginning of August 1955.

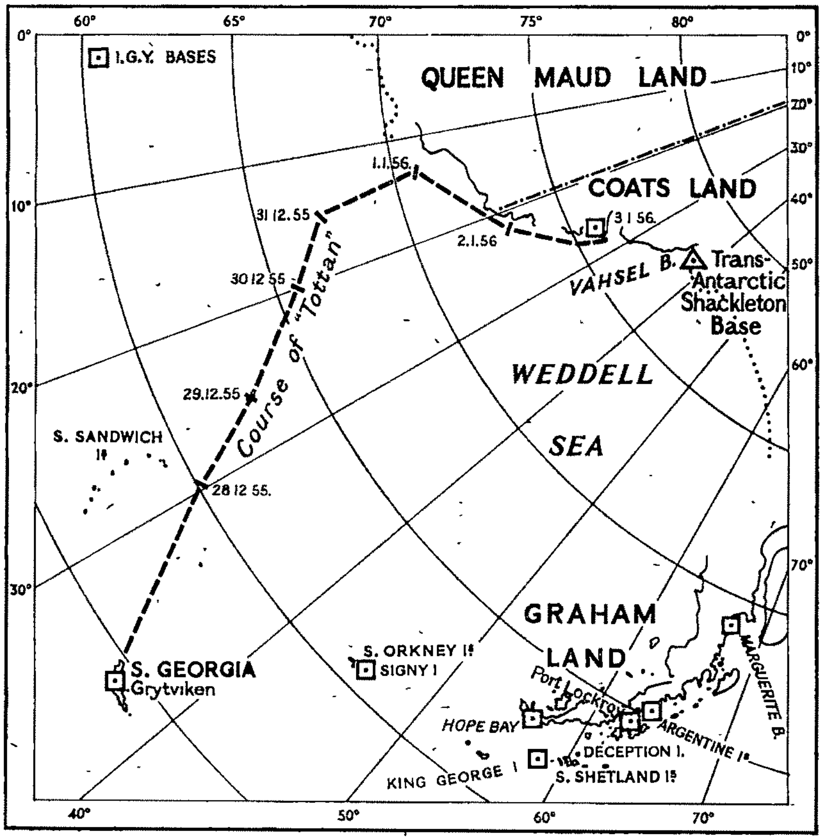
The Weddell Sea has held an ill reputation in the past, but records showed that the ice conditions were adverse only in the western part of the sea, where the pack-ice accumulates in its passage northwestwards. The evidence from Coats Land itself indicated that the Weddell Sea offered no unusual ice difficulties in the eastern and north-eastern approaches. A tongue of pack-ice in the sixties of south latitude stretches eastward from Graham Land. At the eastern end it has been successfully penetrated even by low-powered ships by a route south of the South Sandwich Islands. In January 1912 and again in January 1915 ships broke through to open water; in the case of Shackleton's *Endurance* in 1915, the southern ice edge, reached in lat. 70° S., was found to be separated from the Coats Land ice cliffs by more than a hundred miles of completely open sea. This open water continued as a broad land channel for some 250 miles farther southward along the coast to as far as lat. 76° S. Shackleton took his ship down this land channel partly under sail, running before the wind. This wide open channel was also seen from the air more recently, in December 1951 and January 1952, on flights from the Norwegian base at Maudheim in Queen Maud Land. Both the penetrable tongue and the wide land channel appear to be normal. The secret of entry to the Weddell Sea is to pass through the tip of the tongue in its eastern part and so into land water.

Tentative plans, finally put into operation in August 1955, had already been drawn up for a party of ten men to form an advance unit to erect the living-hut and observing accommodation. There was an early setback as the *Jopeter*, the ship first chartered to carry the party south, was crushed and later abandoned early in September in the ice off East Greenland. The ship selected to replace the *Jopeter*, however, was the well-known *Tottan*, a slightly smaller vessel but with a high reputation for strength and manœuvrability in ice. She has been under the command of Captain Leif Jakobsen, who has had wide experience not only in the difficult ice conditions off East Greenland but also as mate of the *Norsel* in the ice-encumbered waters off Queen Maud Land east of Coats Land. The *Tottan* sailed from Southampton on November 22, little more than three months after the first orders for the hut and equipment had been given. Credit for this speedy carrying out of the Royal Society's plans must go to H.E. the Governor of the Falkland Islands, to the authorities at the Crown Agents, and to Mr. F. K. Elliott, secretary of the Falkland Islands Dependencies Survey.

The *Tottan* reached South Georgia on Christmas Day 1955, and took her departure on December 26, her itinerary being as follows:

December	28	lat.	60° 19′ S.	long.	29° 40′ W.
,,	29		62° 55′ S.		24° 30′ W.
,,	30		65° 25′ S.		20° 00′ W
,,	31		67° 10′ S.		15° 00′ W
January	1		70° 30′ S.		13° 10′ W.
,,	2		73° 40′ S.		21° 05′ W.
,,	3		76° 31′ S.		27° 23′ W.

She met pack-ice three days after leaving South Georgia. Penetrating the tongue took about three more days; and she reached open water in lat. 68° S. She had taken a route in about the fifteenth meridian west of Greenwich with very little ice hindrance, which appears to have been easily brushed aside. She then proceeded, just as Shackleton in the *Endurance*, down a great open water channel into the Weddell Sea.



Part of Antarctica showing some International Geophysical Year bases

On January 6 a base site was finally chosen in approximately lat. 75° 28′ S. The exact position has to be confirmed. The *Tottan* was occupied landing the hut and stores until January 22, when she took her departure back to South Georgia on a seven-day return voyage by a slightly more westerly route. There was apparently nothing exceptional in the season, and both in and out voyages confirmed the forecast about the approachability of the Coats Land coast north of lat. 76° S.

Surgeon Lieut.-Commander Dalgleish has described his arrival at the ice cliffs of Coats Land on New Year's Day. Eastwards was the ice-gripped continent fringed with cliffs of ice; but when looking westwards away from the coast it was easy to imagine the ship was in a tropical sea. For two days the *Tottan* steamed along the ice cliffs in an open sea. On January 3 in lat. 76° S., she found herself in much shallower water—as little as 15 fathoms—and had to move away from the coast. Open leads in the pack led her a little way south of lat. 76°, but this was her farthest; and the head of the sea being at that time unapproachable she turned back north to look for a landing place in a lower latitude. Three possible bays were reconnoitred in the neighbourhood of the wide Dawson–Lambton glacier, and landings made at two of them. Conditions of the land-ice at all three places, however, were unpromising. Fortunately, in about lat. 75° 28′ S., a suitable place was finally found. Orders had been given that no station was to be established unless it could be placed south of lat. 75° S. on the Coats Land coast, this northern limit being set by the knowledge that the area of maximum auroral frequency lies farther south. The place chosen seems to fulfil all the necessary conditions, and is described as completely satisfactory for the scientific programme. It is almost certainly Shackleton's "excellent landing place" described by him in 1915 as Glacier Bay; it has now been named Halley Bay (see p. 606 of this issue).

Dalgleish describes two ice headlands, two miles apart, converging to an apex, where an easy slope gives access to the ice sheet. The ice sheet is considered grounded, and no exposed rock was visible. From the top of the slope there was a gentle rise of 5 ft. per mile to the east. The main continental plateau was about thirty-five miles distant. The base is 1½ miles from the slope and is either on "a low piedmont or a grounded ice-shelf". No evidence of any activity or ice movement was noticed at the base site.

Unloading began on January 6. Conditions were easy for tractors, but the work had to be done mainly at night to avoid the slush. It was now high summer and eleven days of sunshine enabled more than two hundred tons of stores to be taken to safety on the hut site.

About five thousand Emperor penguins were found on the fast-ice in an adjoining bay and must indicate the persistence of similar conditions year after year. A few days after arrival the sea ice on which the penguins had been nesting broke up and the penguins went out to sea. They are expected to return to their nesting site at the end of March and beginning of April, by which time the sea will have begun to freeze.

With Surgeon Lieut.-Commander Dalgleish there are three scientists, Major G. Watson, R.E.M.E., Dr. Stanley Evans and Mr. D. Limbert. During the present reconnaissance year the observations at the base will be on a limited scale. In meteorology, apart from daily observations, a Dobson ozone spectrophotometer will be in use for the first time in high latitudes. There will be no work in geomagnetism, and the magnetic hut is not due for erection until January 1957. Auroral observations will begin using an 'all-sky' camera which has been specially modified by Mr. James Paton. This consists of a mirror and a camera which takes a picture of the sky every minute and gives a complete record of auroral displays. The only ionospheric work to be undertaken this present year will be measurements of atmospheric noise. Glaciology will not be prominent in the reconnaissance year, nor will seismology or gravity.

The latest reports from the Royal Society base are that the skeleton of the hut is in place, but that it will take about two months before the roof and the side walls are complete. Since the *Tottan* left on

January 22, the base has been visited by the *Theron*, Dr. V. E. Fuchs's Trans-Antarctic Expedition ship, on her way south to the head of the Weddell Sea. Dr. Fuchs called again on February 8 after setting up his own base on the Filchner Ice-shelf at lat. 77° 57′ S., long. 37° 16′ W., about twenty-five miles west of Vahsel Bay. In due course it is hoped that an overland route will be established between the bases, which are more than two hundred miles apart.

Plans for the future are that next year the two expeditions will share a large ice-breaking sealer. She will go south in November 1956 carrying eighteen men for the International Geophysical Year party and eighteen men for the Trans-Antarctic party, and will arrive at Coats Land in January 1957. There will be a brief visit by a relief ship in January 1958; and the geophysical party is due to leave the Weddell Sea in January or February 1959 to return to Britain.

CHINESE ASTRONOMICAL CLOCKWORK

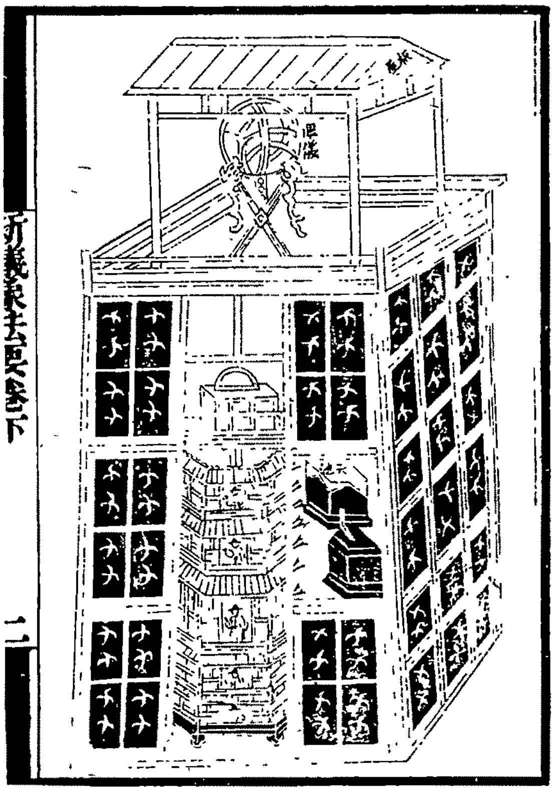
By Dr. JOSEPH NEEDHAM, F.R.S.
Caius College, Cambridge

WANG LING
Trinity College, Cambridge

AND

Dr. DEREK J. PRICE
Christ's College, Cambridge

It is generally agreed that the invention of the mechanical clock was one of the most important turning-points in the history of science and technology. According to the view accepted until recently[1-4], the problem of slowing down the rotation of a wheel to keep a constant speed continuously in time with the apparent diurnal rotation of the heavens was first solved in Europe in the early fourteenth century A.D. Trains of gearing were then combined with the verge and foliot escapement and powered by a falling weight. Recent research has shown, however, that these first mechanical timekeepers were not so much an innovation as has been supposed[5]. They descended, in fact, from a long



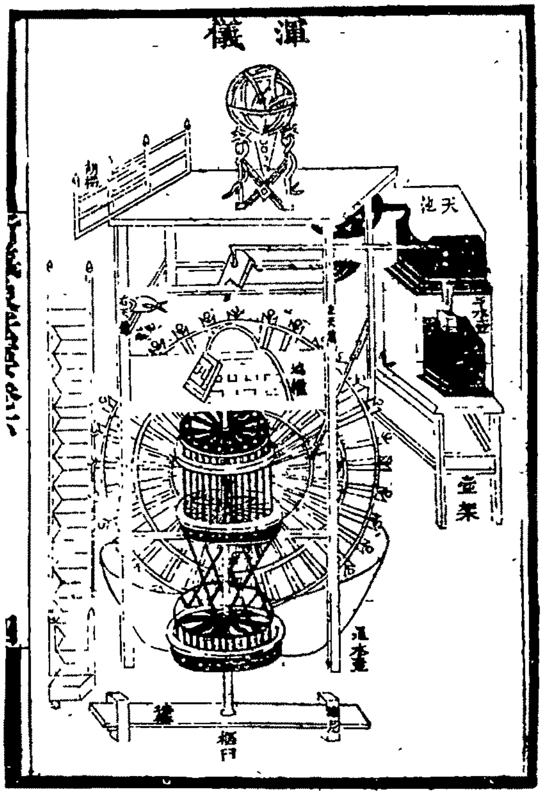


Fig. 1. Astronomical clock of A.D. 1088 from Su Sung's "Hsin I Hsiang Fa Yao", ch. 3, p. 2*a*. External appearance. The armillary sphere on the platform above, the celestial globe in the upper chamber of the tower, and the pagoda with the time-announcing jacks below this. On the right, the housing removed to show the water-tanks. Estimated total height about 30 ft.

Fig. 2. The same as Fig. 1. General view of the works. Vertical shaft with jack-wheels in the foreground, behind this the driving-wheel with its scoops. Water-tanks on the right, part of the anti-recoil device on the left at the top. Escapement not shown in this diagram, though the device above the wheel is probably intended for part of it.

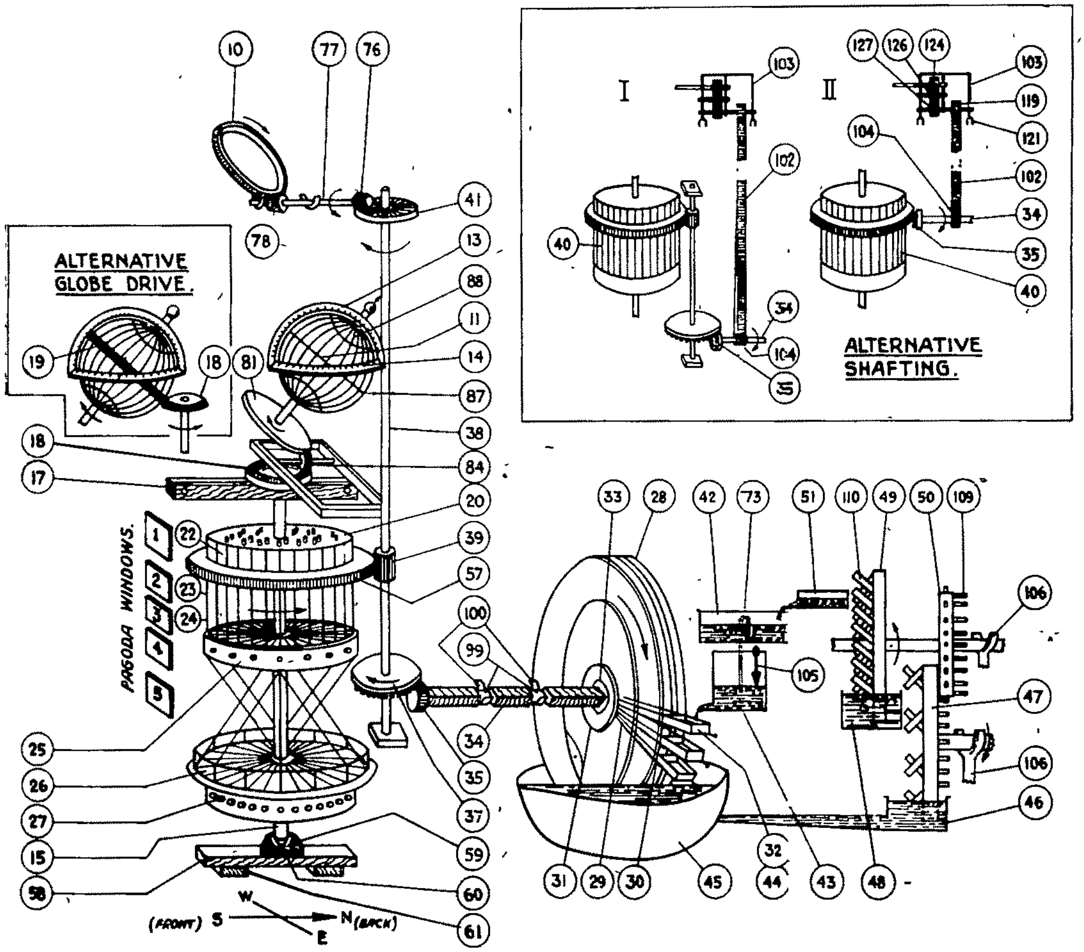

Fig. 3. General reconstruction. The numbers indicate technical terms which will be given and explained in the full publication. Gearing at the top of the jack-wheel shaft on the left drives the celestial globe. The long shaft rotating the armillary sphere was in later models replaced by successively shorter chain drives, as shown in the inset. On the right are the two norias which raised the water to the uppermost reservoir, sufficient for twenty-four hours running. (*Drawn by Angel*)

series of complicated astronomical 'clocks', planetary models, mechanically-rotated star-maps and similar devices designed primarily for exhibition and demonstration rather than accurate time-keeping. Although such devices are of the greatest interest as the earliest complex scientific machines, it has not hitherto been possible to adduce more than a few fragmentary remains, and literary descriptions tantalizingly incomplete, which lack sufficient detail for clear understanding of the mechanical principles involved. But the examination of certain medieval Chinese texts, the relevance of which has not been realized, has now permitted us to establish the existence of a long tradition of astronomical clock-making in China between the seventh and the fourteenth centuries A.D.

The key text is the "Hsin I Hsiang Fa Yao" [New Design for a (Mechanized) Armillary (Sphere) and (Celestial) Globe], written by Su Sung in A.D. 1090, the appropriate sections of which we have fully translated. This describes in great detail an astronomical clock of large size (Figs. 1 and 2) powered not by a falling weight, but by a scoop-wheel using water or mercury. Besides the rotation of the sphere and globe by trains of gear-wheels, the clock embodied elaborate time-keeping jack-work. The escapement consisted of a weigh-bridge which prevented the fall of each scoop until full, and a trip-lever and parallel linkage system which checked the rotation of the wheel at another point. An anti-recoil device was also built in. The basic principle involved is thus more like the anchor escapement of the late seventeenth century than the verge and foliot type, although the time-keeping is, of course, governed mainly by the flow of water rather than by the escapement action itself. This type of effect is therefore the 'missing link' between the time-keeping properties of a steady flow of liquid and those of mechanically produced oscillations. So complete is the description, which has yielded more than a hundred and fifty technical terms of eleventh-century mechanics, that it has been possible to prepare detailed working drawings of the clock (Figs. 3 and 4).

The full understanding of this text has enabled us to interpret many descriptions of other clocks contained partly in the dynastic histories and partly in other sources, some from books now lost, but preserved in the "Yü Hai" encyclopædia of A.D. 1267. Thus an important astronomical clock driven by mercury was built by Chang Ssu-Hsün, a Szechuanese, in A.D. 979. The tradition seems to start with an instrument completed in A.D. 725 by the Tantric monk, I-Hsing, and an engineer named Liang Ling-Tsan, the description of which would not have been

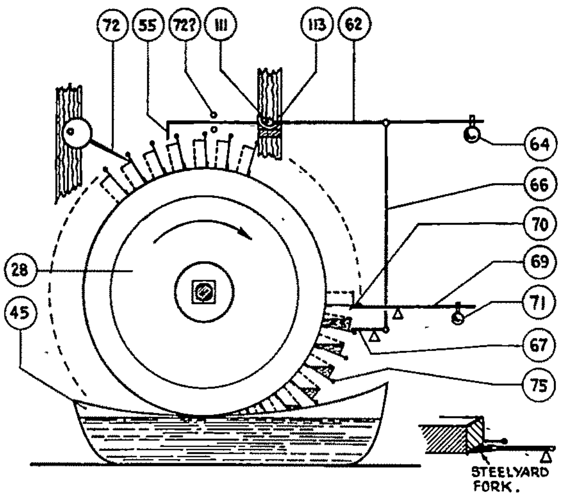

Fig. 4. Diagram of the escapement, with its weigh-bridge and parallel linkwork. The clepsydra flow delivered into the scoop at 70. (*Drawn by Angel*)

comprehensible without thorough prior study of Su Sung's text.

Earlier texts describe celestial globes or demonstrational armillary spheres rotated by clepsydra water. These range from the work of Chang Hêng about A.D. 130 to that of Kêng Hsün about 590, but evidence of any escapement is absent. We supposed at first that these employed only the sinking float of a large clepsydra. This was the system of the Hellenistic anaphoric clock with its rotating astrolabic dial[6], and perhaps also of the famous striking water-clocks of the Byzantine[7] and Arabic[8] culture-areas. But textual and historical considerations incline us rather to the view that the clepsydra water dripped on to a scoop-wheel, turning a shaft with a trip-lug which constituted a pinion of one. This acted on a toothed ring on the apparatus, moving it tooth by tooth.

It thus appears that the Chinese tradition of astronomical clockwork was more nearly in the direct line of ancestry of the late medieval European mechanical clocks. Moreover, the detailed description of this previously unrecognized type of water-driven clock has made it possible to find similar devices incompletely described (perhaps because incompletely known) in Indian[9], Arabic and Hispano-Moorish[10] texts. Of the transmission of influences little can as yet be said, though there are indications that the European centuries just preceding the fourteenth knew devices with water-powered and mechanically checked driving-wheels[11]. This would suggest that the time of transmission was rather that of the Crusades (as in the case of the wind-mill) than that of the Pax Tartarica and Marco Polo.

All the texts now translated, with commentary and discussion, will, it is hoped, be published as a special monograph by the Antiquarian Horological Society, to which the results of the investigation have been communicated.

NUCLEIC ACIDS AND PROTEIN SYNTHESIS

In recent years it has become increasingly evident that the nucleic acids play an important part in cellular metabolism, and the general interest in the recent developments in this field was well demonstrated by the size of the audience which attended the Biochemical Society's symposium on "The Structure of Nucleic Acids and their Role in Protein Synthesis". This meeting was held at the London School of Hygiene and Tropical Medicine on February 18 last.

In opening the morning session, which was concerned mainly with recent chemical and physical evidence about the structure of the nucleic acids, the chairman, N. W. Pirie (Rothamsted Experimental Station), defended the work of P. A. Levene, which of recent years has been criticized for obscuring the issue by over-simplification. He also suggested that some suitable word should be coined to embrace the terms 'purine' and 'pyrimidine'.

The first paper in the symposium was given by Dr. R. Markham (Agricultural Research Council Virus Research Unit, Molteno Institute, Cambridge), who outlined the discoveries which have been made in the past ten years and which have more or less revolutionized ideas about the structure and the complexity of the nucleic acids. Much of his talk was devoted to a discussion of the degradative approaches which have led to the picture of nucleic acids as straight-chain molecules made up of nucleoside residues linked by 3′ : 5′-phosphodiester bridges. He also emphasized the importance of the hydroxyl group at C′2 as a part of the structure of ribonucleic acids which might be involved in the biological transformations of the molecules, and he pointed out that its absence in deoxyribonucleic acids has precluded a chemical investigation of the latter by methods which have proved so successful in the study of the ribonucleic acids. The deoxyribonucleic acids have, however, been found to have structural regularities ; but he doubted whether the self-replicating mechanisms which have been postulated recently by various workers will fit all the experimental observations.

In discussion, Dr. F. H. C. Crick outlined a scheme by means of which he believed these difficulties could be overcome. He also doubted whether the less common purines and pyrimidines have any real biological significance.

The second paper of the morning session was given by Dr. M. H. F. Wilkins (Medical Research Council Biophysics Unit, King's College, London), who described some of the elegant X-ray crystallographic work which has come from King's College, London, and which has been responsible for our present conception of deoxyribonucleic acids as double helices. He pointed out that the X-ray data indicate that the molecule has two grooves of unequal depths, and that in the nucleoprotamines the polypeptide chains lie inside these grooves, the non-basic amino-acid residues occurring in pairs so as to be able to loop away from the main helix. The data obtained with nucleohistones are not so easily interpreted, but they suggest a substantial amount of orientation of the protein on the nucleic acid molecules.

Dr. Wilkins deplored the current tendency of physicists to explain the relationship between nucleic acids and protein synthesis by numerological arguments, and suggested that, among other things, certain of their premises are faulty. This evoked a reply by Dr. Crick, who pointed out that the number of amino-acids in each protein has been found to be essentially the same, namely twenty, if a few minor suppositions are made.

The afternoon session, with Prof. J. N. Davidson (Biochemistry Department, University of Glasgow) in the chair, was concerned with the relationship of the nucleic acids with protein synthesis; he introduced the session with a general survey of the present knowledge of the various sub-cellular elements and the problem of their isolation.

The study of protein synthesis in higher organisms was discussed by Dr. B. A. Askonas (National Institute for Medical Research, London), who described the use of radioactive tracers to follow amino-acid incorporation into proteins in various cell fractions. A particularly suitable system for this kind of experiment is to be found in cells synthesizing protein in response to a specific stimulus such as occurs in immunological reactions. It is, however, difficult to obtain results of this type with sub-cellular preparations, and it is necessary in such cases to follow the labelling of various fractions isolated by physical methods. Fractions rich in nucleic acid are found to have most activity.

Dr. E. F. Gale (Medical Research Council Unit for Chemical Microbiology, Cambridge) described some of the recent work which he has carried out on disrupted *Staphylococcus aureus* suspensions, following the incorporation of labelled amino-acids. Deoxyribonucleic acid is a powerful stimulatory substance and loses its activity on hydrolysis. Ribonucleic acid is not so active, but on enzymic degradation becomes very active indeed. The identification of the various factors influencing the incorporation of specific amino-acids with specific polynucleotides has, however, been found to be incorrect, and it appears that specific substances of unknown nature are liberated when the nucleic acid is broken down.

In comment, Dr. W. E. Cohn remarked that nucleic acid preparations may yet prove to contain substances of which we have no knowledge at present.

The bacteriophage–bacterium system was the subject of the last paper in the session, which was given by Dr. K. Burton (Medical Research Council Cell Metabolism Research Unit, Oxford). This system is of particular interest in view of the injection of virus nucleic acid which is known to take place on infection; but it was pointed out that a not inconsiderable amount of protein is also introduced at the same time into the bacterium. In the case of the *T* even bacteriophages which parasitize *Escherichia coli*, it is actually possible to follow the synthesis of bacteriophage nucleic acid because of the presence of a specific pyrimidine, 5-hydroxymethyl cytosine, in the latter, and it is certain that study of this system will be of great importance in the future. Results obtained so far, however, do not seem to fit with any simple replication mechanism of the types which have been proposed.

The meeting ended with a general impromptu discussion of template mechanisms involving nucleic acids. Although the general tenor of the symposium was somewhat speculative, the interest of the audience and the many questions raised in discussion showed that the choice of subject was a good one, and the Biochemical Society and its symposium organizer, Dr. E. M. Crook, are to be congratulated on the success of the meeting.

OBITUARIES

Prof. W. C. McC. Lewis, F.R.S.

With the death of William Cudmore McCullagh Lewis on February 11, Britain lost one of its finest physical chemists. After graduating with distinction at the Royal University of Ireland in 1905, he carried out research work at the Universities of Liverpool, Heidelberg and London and was appointed lecturer of University College, London, in 1910. The best-known of his many early researches were his experimental verification, with F. G. Donnan, of the Gibbs adsorption isotherm and his theoretical treatment of the Joule–Kelvin effect. These two substantial advances have long since found their way into standard text-books. In 1913 Lewis was appointed to the Brunner professorship of physical chemistry at the University of Liverpool, a chair which he held until his retirement in 1947. He was elected a Fellow of the Royal Society in 1926.

During his first decade at Liverpool, Lewis led an active school in experimental studies of chemical kinetics. The most notable single publication in a long series of papers on catalysis is his "Calculation in Absolute Measure of Velocity Constants and Equilibrium Constants in Gaseous Systems" (1918). Not all the conclusions of this paper have proved to be correct. It is now known, for example, that diatomic molecules do not dissociate by a first-order mechanism, and that activation generally is not by direct interaction with the radiation field. These, however, are points of detail in comparison with his main conclusions, which are that velocity coefficients in gaseous systems can be treated by the methods of statistical mechanics and that in certain examples the rate of chemical change is simply the rate of molecular collisions multiplied by the fraction of the total number of molecules which have sufficient energy. Trautz had independently come to the same conclusion in 1916 but, on account of the First World War, the *Zeitschrift für anorganische und allgemeine Chemie* was not available to Lewis, and both can claim equal credit for their outstanding contribution. The Trautz–Lewis collision theory gave a very considerable impetus to the study of chemical change.

In collaboration with Blair Bell, Lewis led, in the early 1920's, another active team of physical chemists in cancer research. This circumstance probably explains why, like Arrhenius before him, he later transferred his research interest to biochemical and physiological problems.

Lewis is most widely known as the author of "A System of Physical Chemistry", a graduate text-book in three volumes which went into four English editions in nine years. To the task of preparing it he brought the experience of a skilled experimentalist, the wide learning of one conversant with many foreign tongues and the sympathy of one accustomed to teach. His book reveals a breadth of outlook which is not entirely unexpected from one familiar with the methods of research of so many different universities; there is in it no vestige of the narrowness so often found in books written by those who teach only where (and often only what) they were taught. His book is by no means perfect. At the time of its appearance the character of physical chemistry was rapidly changing, and the author must have worked exceptionally hard to keep abreast with the many developments of that period. As things turned out, material which Lewis had to put in an appendix to his third volume appears in the introductory passages of modern text-books. Despite its shortcomings, however, his text-book exerted a wide influence and can truly be described as the first original treatise of advanced physical chemistry in the English language.

Nature had endowed W. C. McC. Lewis not only with a brilliant intellect but also with magnificent physique, so that the reflexion of most men on meeting him was that here was a grand type of man. The dignity of his appearance was heightened by his impeccably correct bearing and mellifluous voice. The frequent gleams of humour in his eye and flashes of Irish wit in his utterances saved him from being ponderous or pompous. He was an extremely retiring man and abhorred publicity. His attendance at public scientific gatherings averaged one in twenty years. He made lasting friends of those whom he taught, and proved himself to be throughout his career a great scientist and a kind man.

E. A. MOELWYN-HUGHES

Dr. Harold King, C.B.E., F.R.S.

DR. HAROLD KING, a former member of the scientific staff of the Medical Research Council, died suddenly at his home in Dorset on February 20 at the age of sixty-eight.

The son of a schoolmaster, King studied chemistry at Bangor under K. J. P. Orton and in 1911 published, with Orton, his first group of papers, on the chlorination of aromatic compounds. From Bangor he moved for a few months to a company of tar distillers at Beckton, but, finding the atmosphere uncongenial, he accepted in 1912 an appointment with Burroughs Wellcome. Here he came into contact with F. L. Pyman, G. Barger and H. H. Dale, and acquired his abiding research interest in the chemistry of pharmacologically active compounds. In 1919, King was asked to join a small group of workers who were to establish the reputation of the new National Institute for Medical Research at Hampstead; here he remained for the rest of his working life.

A man of quiet and retiring disposition, King preferred his laboratory bench to all other attractions, and his gradual emergence as a scientific figure of international repute seemed almost to surprise him. Early contributions on hyoscine, muscarine and the cinchona alkaloids were followed, in 1924, by the first paper of a long series on trypanocidal arsenicals. While no outstanding new drug was synthesized during these investigations, there emerged a much fuller understanding of the relationship between constitution and trypanocidal action, and eventually, in collaboration with the late Warrington Yorke and E. M. Lourie, King developed an entirely new group of chemotherapeutic drugs, the diamidines.

Although probably the most active British chemist of his generation in chemotherapy, with many contributions on trypanocides, antimalarials, amœbicides and on the chemotherapy of virus infections, King's interests ranged over a much wider field, and his most outstanding contributions were in the field of the chemistry of natural products. In 1935, he published in *Nature* a brief note on curare, followed by a masterly series of papers extending over fourteen years in the *Journal of the Chemical Society*; in these he reported methods for the isolation of pure curare alkaloids; he also provided complete proof of the structure of *d*-tubocurarine and related alkaloids and clarified the botanical problem of the origin of the different curares. Moreover, he stimulated work at the National Institute on the polymethylene di-quaternary ammonium salts, simple analogues of tubocurarine, now in general therapeutic use as the well-known methonium compounds.

In 1932 also, King, together with the late Dr. O. Rosenheim, suggested a new structural formula for the steroids, which was quickly accepted as an outstanding clarification of the field, and made possible the rapid progress which followed in elucidation of the structural relationships of the sex hormones and the cardiac aglycones.

Although he did not welcome administrative responsibility, Dr. King was for many years an efficient secretary to the Chemotherapy Committee of the Medical Research Council, and during the War, secretary also to the Committee for Penicillin Synthesis. In 1933, he was elected to the Royal Society, and in 1941 was awarded the Hanbury Medal of the Pharmaceutical Society.

One additional publication deserves special attention, since it relates to King's activity outside the laboratory; in 1946 he read a paper to the South London Entomological and Natural History Society on the "Sex-attractant Principles of Moths". Few men can have derived such constant pleasure from their hobby as did King from his collection and study of British moths. No colleague could regard himself as a friend until he had been privileged to examine that collection, and no other subject could thaw King's natural reserve in the same way. Perhaps this collection showed his true character more clearly than any scientific paper; a lover of order, peace and beauty, King was a true naturalist. Those of us who passed through his laboratory as junior colleagues will always remember him with affection, not only because he was helpful, but also because of his likeable personal idiosyncrasies, his determination to do things for himself, his staunch insularity and his refusal to discourage or disparage the ideas of his juniors, however wild those ideas may have seemed to a man of his scientific insight.

Dr. King married in 1923 Miss E. M. Croft and is survived by her and his one son. T. S. WORK

Dr. Robert M. Yerkes

THE death occurred on February 5 of Dr. Robert M. Yerkes who, for well over fifty years, played a dominant part in the development of animal psychology and, in particular, the study of the behaviour of apes and monkeys. Yerkes graduated in 1899 from Harvard University, where he was given his first teaching post. In 1917, the year the United States entered the First World War, he left to become professor of psychology and director of the Psychological Laboratory at the University of Minnesota. During the course of this appointment he became special adviser on the selection of officers to the Armed Services, and chairman of the Research Information Service of the U.S. National Research Council. He also held a number of other official advisory appointments, and in 1921 became chairman of a Committee on Problems of Sex that was set up by the National Research Council. This body, of which Yerkes continued to be chairman until 1947, was highly influential in developing the study of reproductive physiology and of endocrinology.

Yerkes will be best remembered for his studies of the behaviour of apes; his own research interest was mainly in the question of intelligence and ideational behaviour. His first big monograph on the subject, entitled "Mental Life of Monkeys and Apes", was published in 1916. The work for which he is best remembered was done after 1924, when he was appointed professor of psychology at Yale University. It was during this phase of his career that Yerkes established and organized the Yale Laboratory of Primate Biology at Orange Park, Florida. This Laboratory specializes in work on chimpanzees, and has been responsible not only for most of the behavioural studies that have been made of apes, but also for much of the information we have about their reproductive physiology.

In 1929 Yerkes published, in collaboration with his wife, Ada W. Yerkes, a monumental work called "The Great Apes". This book immediately became, and remains, a source book of information on almost all aspects of the apes except their anatomy. In 1943, shortly before he retired from the active direction of his department at Yale, Yerkes published another book under the title "Chimpanzees: a Laboratory Colony", which is also the authoritative work in its field. S. ZUCKERMAN

NEWS and VIEWS

Industrial Metallurgy in Birmingham: Prof. E. C. Rollason

PROF. E. C. ROLLASON, at present Henry Bell Wortley professor of metallurgy in the University of Liverpool, has been appointed to the chair of industrial metallurgy in the University of Birmingham in succession to Prof. A. J. Murphy, who has been appointed principal of the College of Aeronautics (see *Nature*, **176**, 55; 1955). Prof. Rollason has distinguished himself in both university work and industry. He took his M.Sc. degree at Birmingham in 1932 and gained his first experience of teaching at the County Technical College, Wednesbury. Returning as senior lecturer to the Department of Metallurgy in Birmingham in 1935, he carried out research which led to the Ph.D. degree, and contributed to the development of teaching methods in the Department. At the outbreak of war, Prof. Rollason was seconded to the firm of Murex Welding Processes, Ltd., to pursue researches on the welding of armour plate and other important defence problems. In 1942 he accepted the post of research manager; he later became a director of the Company, and played an important part in building up the Research Department. Prof. Rollason returned to academic life in 1951 when he was appointed to the chair of metallurgy at Liverpool, where he has devoted himself to the reorganization of the laboratory training and the development of the undergraduate and postgraduate schools. Prof. Rollason has taken an active part on the Research Board and committees of the British Welding Research Association, and is the author of many papers on the metallurgy of stainless steel, metal spraying, and the welding of ferrous and non-ferrous metals, as well as of a successful text-book, "Metallurgy for Engineers".

Millport Marine Station, Scottish Marine Biological Association: Mr. E. Ford

MR. E. FORD is retiring from the joint post of director of the Millport Marine Station and secretary to the Scottish Marine Biological Association, which he has held since 1949. Previously the secretaryship had been a part-time post not held by the director of the Station. At the same time as Mr. Ford was appointed, the Association took under its auspices the Oceanographic Laboratory at Edinburgh and, in his capacity as secretary, Mr. Ford became responsible for both laboratories. He successfully achieved the formidable task of administration involved in the organization of the Association's office at Millport, from which the affairs of both laboratories are controlled. During the seven years of his directorship at Millport, Mr. Ford has been responsible for major developments, and the Station has become a research institute of major importance. Much of the research accommodation has been rebuilt and enlarged, the library reorganized and a workshop and stores erected. With aid from the Carnegie Trust of the Universities of Scotland, a new aquarium has been erected and a new classroom is now just completed. The scientific staff has increased, and a second research vessel has been acquired.

Dr. C. H. Mortimer

DR. C. H. MORTIMER, who succeeds Mr. Ford, has been for some twenty years a member of the staff of the Windermere Laboratory of the Freshwater Biological Association, reaching the grade of senior principal scientific officer. After graduating in zoology from the University of Manchester, Dr. Mortimer took a research degree at the University of Berlin. His first work was on cytology and reproduction in *Cladocera*; but after appointment to Windermere his interest moved to the physical and chemical aspects of organic production in freshwaters. He has carried out notable research on the exchange of dissolved substances between mud and water and more recently on water movements. This has carried him as far afield as Lake Michigan in the United States and Loch Ness in Scotland. There is much in his approach to the problems of water movements and fertility which is common to freshwaters and the sea. His change, therefore, from the one type of aquatic research to the other is natural and should prove highly productive.

Royal Geographical Society: Medals and Awards, 1956

H.M. The Queen has approved the award of the Royal Medals of the Royal Geographical Society as follows: *Patron's Medal:* John Giaever, Norwegian Polar Institute, leader of the Norwegian–British–Swedish Antarctic Expedition, for contributions to polar exploration; *Founder's Medal:* Charles Evans, leader of the Kangchenjunga Expedition 1955, for contributions to Himalayan exploration.

The Council of the Society has made the following awards: *Murchison Grant:* Dr. Alice Garnett, for contributions to physical geography and geographical education; *Mrs. Patrick Ness Award:* Robert Dovers, Australian National Antarctic Research Expedition, for contributions to Antarctic exploration and mapping; *Gill Memorial:* R. A. Skelton, superintendent of the Map Room, British Museum, for studies in the history of cartography and exploration; *Back Grant:* Richard Hamilton, senior scientist, British North Greenland Expedition; *Cuthbert Peek Grant:* David Oates, Fellow of Trinity College, Cambridge, for archæological surveys in Iraq.

Imperial Chemical Industries Transfer Scholarships

With the aim of increasing the number of university science graduates, Imperial Chemical Industries, Ltd., is to provide annually over the next few years about fifty scholarships of a new type, designed to enable students who have not specialized in science at school to commence serious study of science at the university itself. To be known as I.C.I. Transfer Scholarships, they will make it possible for students to take a preliminary science course of one year's duration at certain universities, and then go on to take normal honours science courses. The scholarships will be available for the first time during 1956–57 at the University of Cambridge; Imperial College of Science and Technology, London; King's College, Newcastle; the University of Liverpool; and the University of Oxford. The value of the scholarships will be based on State Scholarship rates, and there will be continuing small awards to scholars who successfully pass on to take honours science courses. The scheme has the full support of the Ministry of Education and of the universities and colleges concerned. Imperial Chemical Industries believes that these scholarships will help to solve one of the major problems of present-day industrial Britain—namely, the training of a greatly increased number of scientists and technologists. There are many young men who have taken arts courses at school and done well in them, but who, on going forward to the university, may wish to specialize in science subjects rather than taking advanced work in arts. At present they are not able to do this, for unless they have studied science at school they are unable to enter honours schools of science and technology in English universities. The scholarships are expected to produce 40–50 additional scientists or technologists per year, but that will be only a part, and probably a small part, of their influence if they serve to encourage a wider provision of elementary science courses in the universities.

Royal Society Antarctic Station at Halley Bay

All the authorities concerned have agreed to a recommendation of the Council of the Royal Society that the bay in Coats Land, Antarctica, in which the advance party of the Royal Society Antarctic Expedition for the International Geophysical Year, led by Surgeon Lieutenant-Commander D. Dalgliesh, landed from the M.V. *Tottan* on January 6, be called Halley Bay; and that the site of the hut, which is 1½ miles inland from the coast, be known as Royal Society Base (see p. 598 of this issue). Edmond Halley was a former secretary of the Royal Society, and this year is the tercentenary of his birth. His scientific work made pioneer contributions to many of the subjects which will receive further concentrated observation during the International Geophysical Year. Thus he studied the theory of the Earth's magnetic field, and in 1698 and 1700 made two voyages to the North and South Atlantic Ocean, which resulted, in 1701, in the publication of the first magnetic chart. His further studies enabled him to realize that the aurora borealis is associated with the Earth's magnetism. He discussed with much care the problem of trade winds, which were very important to the sailing ships of his day, and carried out some fundamental work on ocean currents, and noticed the variation of gravity as he approached the equator.

Department of Scientific and Industrial Research Bill

The Department of Scientific and Industrial Research Bill (London: H.M.S.O. 6*d*. net), issued simultaneously with the Department's annual report for the year 1954–55, and which received its first reading in the House of Lords on March 20, proposes to replace the present Advisory Council for Scientific and Industrial Research by an executive Council, referred to in the Bill as the "Research Council". The body, like the present Advisory Council, will comprise persons eminent in industry and in science, but will in future be in executive charge of the Department, subject to the over-riding responsibility of the Committee of the Privy Council for Scientific and Industrial Research and of the Lord President of the Council as its chairman. The Bill also provides in a specific Act of Parliament for the expenditure of the Department to be met out of moneys provided by Parliament, and the Imperial Trust for the Encouragement of Scientific and Industrial Research is accordingly dissolved. There appears to be nothing in the Bill which provides specifically, however, for financing the work of the Department other than on a year-to-year basis. The present annual report, while noting an increase of £260,000 in the net estimate of the Department for 1955–56 compared with 1954–55, records a failure to maintain the annual rate of increase in staff of two hundred required by the five-year plan. Some concern is expressed about the work of the research associations, more particularly in the smaller industries, and the advantage of linking the research association serving such an industry with an established and related research association serving a larger industry is emphasized. Confidence is none the less expressed that during the past five years the research association movement as a whole has demonstrated its strength and vitality and that most of British industry believes firmly in the value of its research associations.

Awards for Advanced Courses at Technical Colleges

In a written answer on March 15 to a question in the House of Commons, the Minister of Education, Sir David Eccles, said that during 1953–54, the latest year for which figures are available, 9,829 awards were obtained by students of advanced courses at technical colleges. Of these, 237 were internal degrees in science and 209 internal degrees in technology at the University of London; 722 external degrees in science and 283 external degrees in technology; 110 associateships of the Royal Institute of Chemistry; 248 Higher National diplomas; 6,940 Higher National certificates; 350 college diplomas (technical); and 90 college diplomas (science).

Agricultural Research in Scotland

In a written reply on March 9 to a question in the House of Commons, the Secretary of State for Scotland, Mr. J. Stuart, said that eight institutes for agricultural research in Scotland are financed by the Department of Agriculture for Scotland and administered by independent governing bodies under the general scientific guidance of the Agricultural Research Council. Expenditure on agricultural research for the current financial year amounted to £875,800, of which £140,050 was capital expenditure; on agricultural education to £362,300, of which £148,300 was capital and £159,000 maintenance expenditure on agricultural colleges, and £55,000 on farm schools; and on agricultural advisory services to £537,400. These figures take no account of expenditure at Scottish universities on agricultural education met by the Universities Grants Committee.

Projected Giant Radio Telescope in Australia

In 1954 the Carnegie Corporation of New York offered the Australian Commonwealth Scientific and Industrial Research Organization 250,000 dollars towards the construction of a giant radio telescope for its Radiophysics Division, subject to the provision of sufficient further funds from other sources. Since then the Australian Commonwealth Government has promised to pay half the cost of the project, and further private donations have been received including a second 250,000 dollars from the Rockefeller Foundation. These generous contributions are sufficient to permit the construction of an instrument, and arrangements have been made with the London firm of consulting engineers, Freeman, Fox and Partners, to undertake a design study. In this work they will be assisted by Dr. B. N. Wallis. Details of the instrument will depend on structural factors and available finance; but the broad specification is for a steerable reflecting telescope of the maximum feasible aperture which will work without deterioration in performance down to a wave-length of 21 cm. (the atomic hydrogen spectral line). A corresponding instrument, of 250-ft. aperture, is nearing completion at Jodrell Bank in England, and the construction of others is contemplated in the United States; but this is the only one projected for the southern hemisphere. It will be invaluable in completing the coverage of the whole sky, and, with this in mind, the International Astronomical Union and the Royal Astronomical Society have each expressed themselves as strongly favouring the project.

Natural History of Coral Atolls

During the American atom-bomb tests in the Marshall Islands in 1946, known as 'Operation Crossroads', comprehensive investigations on the geology, ecology and oceanography were carried out not only at Bikini atoll where the weapons experiments took place but also, as controls, at the neighbouring atolls of Eniwetok, where the ecology had been somewhat disturbed by wartime military operations, and at Rongerik and Rongelap, which had scarcely been touched by the outer world. The studies were continued by expeditions in 1947 and 1950, when the geological structure at Bikini was explored by several diamond-drill holes, and when seismic refraction and aerial magnetic surveys were made over this atoll, an adjacent guyot and the surrounding sea-floor. The conclusions of the large team of workers engaged in this project have lately been published by the United States Geological Survey (Professional Paper No. 260, 1955; parts *A–R*, 684 pp., 218 text figs. and 224 plates). Along the submarine slopes of Bikini and of the nearby seamount, specimens of olivine-basalt, basaltic ash and basic volcanic tuff were dredged from depths of 1,000–2,010 fathoms (6,000–12,060 ft.), providing the first direct evidence of the volcanic nature of the base on which a coral atoll is built. In the deepest borehole (2,556 ft.) the coral reef was not bottomed, the strata penetrated consisting entirely of fine detrital limestones, in composition almost a pure calcium carbonate, all originally deposited in lagoonal waters not less than 30 fathoms in depth. The oldest sediments reached are of (?) Oligocene age. Seismic refraction studies have confirmed and extended the results of drilling by indicating that several thousand feet of relatively unconsolidated calcareous rock overlies a volcanic core with a highly irregular topography. Unlike the borings undertaken at Funafuti atoll (to a depth of 1,114 ft.) in 1896–98 and at North Borodino (1,416 ft.) in 1934–36, the drilling at Eniwetok (1,285 ft.) and Bikini (2,556 ft.) has yielded cores of limestone rock which is quite free from dolomitization. It is a measure of the intensity of the collecting carried out during the recent surveys that more species of corals are now known from Bikini atoll than from anywhere else in the world.

Animal Husbandry

The sixth holder of the Devon County Agricultural Association Lectureship endowed at Seale Hayne Agricultural College was Prof. J. E. Nichols, of the University College of Wales, and in his series of four lectures on "Animal Husbandry", given during 1954–55 and now published (pp. 40. Newton Abbott: Seale Hayne Agricultural College, 1956; 4s.), he deals with general principles and then the particular problems of beef and dairy cattle, sheep and pigs. His final lecture is concerned with the methods and aims of to-day and to-morrow. In the first two lectures he gives particular attention to the sequences of change in bodily form and function in relation to nutritional requirements and to costs: to the interacting factors which affect beef and milk production and, in particular, the need for cowmanship. In his third lecture the differences in husbandry arising mainly from fertility-rates are discussed with respect to sheep and pigs, and in his final lecture an attempt is made to bring the present and the immediate future into perspective. Prof. Nichols points out that intensive management is best reserved for the phases during which intensive production takes place in order to reduce wastage of stock and conserve feed resources. In general, intensive conditions—whether they refer to housing, to feeding, to control or to stockmanship—are most needed and are best applied to the peak periods of lactation, to before and just after parturition, and again to the finishing period of bacon, pork, mutton and beef. So far as cattle are concerned, as part of the requirements for intensification, the simple point of dehorning comes into the picture; in itself it enables saving in space as well as of energy to be made.

Soil Science in New Zealand

The New Zealand Society of Soil Science held its first conference, under the presidency of Mr. N. H. Taylor (director of the Soil Bureau, N.Z. Department of Scientific and Industrial Research), as Section M of the eighth New Zealand Science Congress at Auckland in 1954. The proceedings have now been published (N.Z. Soc. Soil Sci., 54 Molesworth Street, Wellington, N.Z.; pp. 32; 4*s*.), and the presidential address issued as a reprint from the *Transactions of the Royal Society of New Zealand* (**82**, 961; 1955; 1*s*.). In his address, "The Role of Soil Science in New Zealand Problems", Mr. Taylor discussed the subject under four main headings: problems arising from the interdependence of land use and society, and from the use of soils for engineering purposes, for the growing of plants or for the support of animal life. Practical examples mentioned are the selection of the most suitable sites for urban development, road foundations and pipe-line corrosion, while on the biological side are questions of irrigation and forestry or the relationship between soil and the incidence of dental caries. During the conference, symposia were held on forest soils, the aims and values of soil analyses and on the pumice soils. Full summaries of the papers read on each occasion are published in the proceedings, together with the discussion that followed. Shorter abstracts are given of the papers contributed at other sessions.

Automatic Recording of Temperature and Vapour Pressure or Dew-point

In normal measurements of the humidity of the air near the surface, readings are taken of dry- and wet-bulb temperatures, and the vapour pressure, dew-point and relative humidity are calculated from tables. For automatic recording there are available the thermograph, giving a continuous record of dry-bulb or wet-bulb temperatures, and the hair hygrograph, giving a record of relative humidity. Again, the vapour pressure and dew-point have to be calculated from tables. To study the water economy of plants, continuous records of vapour pressure and dew-point are needed, and to obtain these Dr. U. Berger-Landefeldt, of the Technical University of Berlin, has devised an automatic electrical recorder which he describes in the December issue of *Weather* (**10**, 405; 1955). Continuous readings of wet- and dry-bulb thermometers are made and are arranged by suitable circuits to solve the hygrometric formula and give continuous records of dry-bulb temperature, vapour pressure and dew-point. Records obtained by the instrument are shown in the article, and it is explained how the large variations in vapour pressure of 8 mm. of mercury are due to the vigorous transpiration of the alfalfa plants over which the instrument was placed.

Formation and Properties of Diamonds

In a paper entitled "Diamant" (*Zprávy Výzkumného ústavu pro minerály v Turnově*, 4, 577+33 figs.; 1955; Czech, with Russian, English and German summaries), Dr. Primus Ružička offers an explanation of the formation of diamond by the reaction $2CO \rightarrow CO_2 + C$ under great pressure, the pressure finally building up enough to break through the sedimentary rocks and emplace the pipes of kimberlite. He employs this theory to link up a number of observations: sharp octahedra and holohedral forms crystallized more slowly and at lower pressures than rounded crystals, which mostly belong to the ditesseral polar (blende) symmetry class. Type II diamonds crystallized slowly at a lower pressure than type I; and the lamellar structure common in type II diamonds is due to the intercalation of layers of a graphite or 'pseudo-graphite' structure. Bort is regarded as a late product, formed during and after the emplacement of the kimberlite. An explanation of the differences, particularly in crystal habit, between diamond from different localities is offered. In the final sections (pp. 91–114), the anisotropy of the hardness of diamond is discussed, particularly in connexion with the industrial applications of diamond.

Earthquakes during February

During February the greatest earthquake was of magnitude 7¼, and had its epicentre south of Honshu, Japan, with depth of focus 450 km. Earthquakes of magnitude between 6 and 7 occurred on February 1 in the Marianas Islands; on February 9 and later, aftershocks in Lower California; on February 12 and later, aftershocks near the north-west coast of Luzon, Philippine Islands; and on February 19 in the Queen Charlotte Islands. A shock on February 1 in the Fiji Islands had a depth of focus of 600 km. The swarm of shocks, with the principal one on February 9, in Lower California (epicentre south of the point 32° N., 116° W.) did minor damage in the Imperial Valley and at San Diego, and many of the shocks were felt in Los Angeles. Of this swarm, twenty-nine shocks greater than magnitude 5 occurred during February 9–17, and according to the seismological laboratory at Pasadena the later epicentres were somewhat to the east of the principal one. On February 14 an earthquake with its epicentre near the east coast of Honshu caused several injuries and minor property damage in Tokyo. Its magnitude was 5¾ and depth of focus 60 km. On February 15 in Peru an earthquake was responsible for two deaths in the Callehon Huaylas region, while on February 20 in Turkey an earthquake at Eskisehir caused extensive property damage and was responsible for the deaths of four people; many others were injured.

Open Days at the Atomic Energy Research Establishment, Harwell

The Atomic Energy Research Establishment at Harwell was founded ten years ago, and, to mark the occasion, a series of 'open days' is to be held in the week ending June 2. On the first four days, members of both Houses of Parliament, correspondents of the British, Commonwealth and foreign

Press and representatives of the neighbourhood will be invited to tour the establishment. On June 1 there will be a 'university open day', when scientists and technologists from universities and Government research establishments and representatives of industry will be invited. As a result of the changes in security classification made before the International Conference on the Peaceful Uses of Atomic Energy at Geneva last year, much of the work at the Establishment is no longer subject to security restrictions. Consequently, visitors will have more freedom to see a wider range of work at Harwell than was possible until recently.

Society of Chemical Industry : Seventy-fifth Annual Meeting

In connexion with the seventy-fifth annual meeting of the Society of Chemical Industry, which will be held in London during July 9–14, a series of lectures will be given under the title of "Achievements of Industrial Chemistry". They will be introduced by Dr. L. A. Jordan on July 11, speaking on "Modern Methods of Research", and thereafter they will fall into two parallel series. The first series, under the title of "Products of Industrial Chemistry", will be as follows : new products of the fermentation industry, by J. J. H. Hastings (July 12) ; hydrocarbon macromolecules, by C. W. Bunn (July 12) ; carbohydrate macromolecules, by Prof. M. Stacey (July 13) ; nitrogen- and chlorine-containing macromolecules, by Prof. H. W. Melville (July 13). The second series will be on "Tools of Industrial Chemistry", and will be as follows : metals as plant construction materials, by Dr. N. P. Inglis (July 12) ; non-metals as plant construction materials, by Herbert W. Cremer and G. Brearly (July 12) ; manufacturing techniques, by W. d'Leny (July 13) ; records and control, by Dr. G. M. Dyson (July 13).

The Night Sky in April

New moon occurs on April 11d. 02h. 39m., U.T., and full moon on April 25d. 01h. 40m. The following conjunctions with the Moon take place : April 4d. 05h., Mars 4° S. ; April 11d. 17h., Mercury 4° S. ; April 14d. 14h., Venus 4° N. ; April 19d. 19h., Jupiter 6° N. ; April 27d. 05h., Saturn 3° N. In addition to these conjunctions with the Moon, Venus is in conjunction with Aldebaran on April 14d. 20h., Venus 9·1° N. Mercury is too close to the Sun in the first half of the month for observation, but after that it can be observed in the evening ; its time of setting on April 30 is 21h. 25m., which is two hours after sunset. Its stellar magnitude varies from −1·2 to 0·2, and the visible portion of its illuminated disk from 0·880 to 0·460 ; its distance from the Earth is 125 and 85 million miles on April 1 and 30, respectively. Venus sets at 23h., 23h. 35m. and 23h. 40m. at the beginning, middle and end of the month, respectively, its stellar magnitude varying between −3·9 and −4·1, and its distance from the Earth between 75 and 54 million miles ; the visible portion of the illuminated disk varies from 0·570 and 0·401. Mars rises at 3h., 2h. 35m. and 2h. on April 1, 15 and 30, respectively, stellar magnitude 0·7–0·3, the increase in brightness being due to the distance from the Earth decreasing from 121 to 98 million miles ; at the beginning of the month it lies a little south of *h* Sagittarii, and its eastward movement is easily detected by observing its positions with reference to this star over a few nights. Jupiter is visible throughout the night, setting in the morning hours at 4h. 20m., 3h. 20m. and 2h. 20m. on April 1, 15 and 30, respectively. Its stellar magnitude varies from −1·9 to −1·7 owing to its distance from the Earth increasing from 435 to 457 million miles. Saturn rises at 23h. 05m., 22h. 05m. and 21h. at the beginning, middle and end of the month, respectively ; its westward movement can be noticed by comparing its positions during the month with β and ν Scorpii, and its stellar magnitude varies from 0·5 to 0·3 owing to its distance from the Earth decreasing from 866 to 839 million miles. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich : April 2d. 4h. 08·4m., 21*G* Sgr. (*R*) ; April 17d. 23h. 13·1m., 1 Cnc. (*D*) ; April 19d. 0h. 28·5m., 60 Cnc. (*D*) ; April 21d. 23h. 03·4m., *e* Leo. (*D*), *R* and *D* referring to reappearance and disappearance, respectively. The Lyrid meteors attain a maximum about April 21, but moonlight will make their observation very difficult.

Announcements

Dr. Alexander Muir, head of the Pedology Department, Rothamsted, and the Soil Survey of England and Wales, has been appointed deputy director (Soils Division) of Rothamsted Experimental Station in succession to the late Dr. E. M. Crowther.

The following appointments in the University of London have been announced : Dr. E. G. Healey, lecturer in zoology in the University College of Wales, Aberystwyth, to the University readership in zoology tenable at Bedford College ; Dr. D. C. Spanner, lecturer in plant biophysics at the Imperial College of Science and Technology, to the University readership in botany tenable at Bedford College.

The University of Leeds has appointed Dr. H. C. Versey, reader in applied geology, to a personal chair in the Department of Geology. Dr. P. Padget has been appointed Oppenheimer Geological Fellow in the Institute of African Geology of the University.

The annual general meeting and conference of the Mammal Society of the British Isles will be held in the Zoology School of the University of Cambridge during April 6–9. On April 6, at 8.30 p.m., a public lecture on "The Mammalian Placenta" will be given by Prof. J. D. Boyd, professor of anatomy in the University. Further information can be obtained from the conference secretary, K. M. Backhouse, Department of Anatomy, St. Bartholomew's Hospital Medical College, Charterhouse Square, London, E.C.1.

The Institution of Mechanical Engineers has recently established a set of lectures for boys, to be called the Leonardo da Vinci Lectures, and the first three will be given on April 9, 10 and 11 (at 3 p.m.) as follows : "Fundamental Energy", by Prof. D. G. Christopherson (professor of mechanical engineering, Imperial College of Science and Technology, London) ; "Applied Energy", by Sir Claude Gibb (chairman and managing director, C. A. Parsons and Co., Ltd.) ; and "Nuclear Energy", by Sir Christopher Hinton (member for engineering and production, United Kingdom Atomic Energy Production). Tickets (which are free) for one or more lectures and further information can be obtained from the Secretary, Institution of Mechanical Engineers, 1 Birdcage Walk, London, S.W.1.

Erratum. In the article "Polar Wandering" in *Nature* of March 24, on p. 551, col. 2, par 2, the second quotation should begin with the word "We" in line 10.

AGRICULTURE IN THE UNIVERSITY COLLEGE OF THE GOLD COAST

By Prof. JOHN PHILLIPS

THE Cocoa Marketing Board of the Gold Coast, with the approval of the Government, has made available to the University College of the Gold Coast the sum of £1 million for the purpose of establishing and endowing an Agricultural Research Station in the Forest Region. Of this amount, the sum of £750,000 has been allocated for investment for staffing and other recurrent expenditure likely to be associated with the proposed Station, while the sum of £250,000 is to be available over the course of the next four years for purposes of capital development.

At a ceremony at the Agricultural Research Station of the Department of Agriculture of the College, at Nungua, near Accra, a cheque for £750,000 and one for £40,000 as the first contribution toward capital needs were presented by the chairman of the Cocoa Marketing Board to the Principal of the University College on February 28.

Briefly, the objectives of the proposed centre, which is to be established in an area of forest on soils considered to be typical of a large area of the forest region, include: (1) Provision of educational facilities for students of agriculture—undergraduate and senior. (2) The investigation of problems in the management of forest soil, including the possibilities of improving on existing practices in 'shifting cultivation' or 'bush fallowing' and the enhanced production of food and commodity crops both annual and perennial. (Among the commodity crops would be cocoa, coffee, cola, citrus, banana, pineapple—and by some special arrangement relating to site, aspects of oil palm production.) (3) Through studies both at and beyond the centre, the gathering of information relating to the economics of production of selected commodity and other crops, with emphasis on cocoa. (4) Study of problems of production, within the forest region, of poultry, pigs and sheep in certain circumstances. (5) Application of special techniques in the removal of woody growth and the cultivation of forest soil—bearing in mind the dangers of extensive and prolonged exposure of these soils to insolation and heavy and consistent rainfall. (6) The organization of a centre on which professional advisory service of a non-routine nature relating to forest agriculture could be based. (7) Establishment of a centre at which scientific and other research workers concerned in the problems of forest agriculture could work, on invitation, from time to time.

The proposed Station is a logical successor to the first research centre established by the University College in 1952 at Nungua, on the Accra Plains, for students of agriculture and for research into the classification and development of soils; crop production under irrigation and on rain-fed land; animal production and pasture management; aspects of soil and water conservation; mechanization of agriculture and agricultural management and economy. The progress at this Station has been sufficiently encouraging to attract the interest of the authorities to an extension of the University College's activities to the most important economic region in the country, that of the mixed evergreen forests.

The University College is in special relationship with the University of London in respect of academic standards, examinations and the conferment of degrees. At the present there are eleven men reading agriculture in the first, three in the second and three in the final year of the agricultural course proper. Special scholarships for men reading agriculture at the College are offered by the Cocoa Marketing Board and the Agricultural Development Corporation of the Gold Coast. A wide range of research by members of the staff is in progress.

THE ART OF SCIENCE

PROF. L. C. BEADLE'S inaugural address, "The Art of Science", which he delivered on October 28, 1954, at Makerere University College of East Africa, Kampala, Uganda, on taking up the chair of biology there, and which has now been published*, is a brilliant exposition of the thesis that every educated person should know something of the history of science and of the nature of creative research. No summary can do justice to an address which abounds in humour, in sense and frank avowals of the author's convictions, but which can scarcely be quoted without distorting the balance of his argument. He starts by insisting that the inclusion of a subject in the curriculum of a university cannot be justified solely on grounds of utility and that no one can fully understand the nature of science without some knowledge of its history. He pauses in his survey of the history of science to observe that the medieval conception of science as a finite body of established facts is exactly what science is not, and to comment that so far there has been a sufficient number of practising scientists in the teaching profession to frustrate the attempts made during the present century to revive the conception through the invention of examinations. Turning to the biological sciences, he points out that the main creative act in biological research is the decision as to what the problem is, and then the posing of the right questions; he does not believe that the biologists can entirely avoid considering the problem of mind and body. If, however, the great progress now being made, with the aid of new techniques, in the physiology of brain and nervous system, on one hand, and in the study of animal behaviour, on the other, leads to the two streams meeting at any point, there should be results of great practical value, and the combined streams might be deep enough for the psychologists and philosophers to navigate.

In dealing finally with the question, "What is the art of science?", Prof. Beadle remarks that the first and greatest exponents of the scientific method,

---

* The Art of Science: an Inaugural Address delivered at Makerere University College of East Africa, Kampala, Uganda, on October 28th, 1954. By Prof. L. C. Beadle. Pp. iii+32. (London: Oxford University Press, 1955.) 3s. 6d. net.

Bacon and Descartes, though themselves creative thinkers, apparently misunderstood the true nature of creative work. Both seem to have missed the point that scientific discovery is primarily a matter of intuition, that is to say, it is an art. The most essential feature of a creative scientific thinker, Prof. Beadle insists, is his power of imagination and intuition; and knowledge and experience, such as can be got from formal education, are the background from which spring those imaginative flights which are the essence of scientific discovery. He suggests that the greatest single need for the scientific development of Uganda is that the young children should be encouraged, more than they are, to play and experiment. It is the task of the schools to preserve the experimental and imaginative outlook and to protect it against the pernicious influence of examination syllabuses; and it is the task of the universities, the demands of which determine so much the teaching syllabuses in schools, to frame their demands so as to encourage the schools to teach real science, and also to send them teachers who really understand what science is.

EFFECT AT GROUND-LEVEL OF GAS FROM A CHIMNEY-STACK

THE determination of the maximum concentration at ground-level of gas emitted from an industrial chimney-stack is an important problem in the application of meteorology to health. Sutton[1] showed that the concentration at ground-level downwind from the chimney of gas at the same temperature as the surrounding air drifting out of the top rises to a maximum with distance from the chimney and then falls off. He gave a formula for the maximum concentration in terms of wind speed, height of chimney, the atmospheric turbulence coefficients and the atmospheric stability. Usually, the gas is hotter than the surrounding air and has an appreciable vertical speed at the top of the chimney. Both factors cause the gas plume to have a vertical component of speed for some distance from the chimney. The centre line of the plume gradually bends over to become horizontal along the wind at a great distance from the stack.

Recently, Dr. A. C. Best[2] has examined, with the view of helping the stack designer, the relative merits of the following three formulæ for finding the maximum concentration at ground-level of gas from a heated elevated source: (*a*) an extension of Sutton's 'cold' gas formula; (*b*) a theoretical one due to Bosanquet, Carey and Halton[3]; and (*c*) an empirical one, suggested in the United States at the Atomic Energy Station, Oak Ridge[4]. Sutton's 'cold' gas formula is applied to the 'hot' gas problem by replacing the chimney by one at a height greater by a length proportional to u^{-3}, where u is the wind speed. Dr. Best shows that the other two formulæ are equivalent to treating the problem in the same way but with additional heights, for (*b*) proportional to u^{-2} (approximately), and for (*c*) to u^{-1}. He calculates the maximum values of concentration of gas at ground-level for various realistic values of wind speed, height and diameter of chimney, and rate of heat output by the chimney relative to the surrounding air, for example, speed of efflux 5 and 15 m./sec., diameter 5 and 10 m., heights 50, 100 and 200 m., and heat output 10^5–10^9 cal./sec.

Formulæ (*a*) and (*b*) give values with ratios mostly nearly unity and with a maximum of 1·66, and formulæ (*b*) and (*c*) give ratios twenty-five of which were less than 2, thirty-eight less than 3, and with the greatest ratios 4·3, 5·6 and 6·4 occurring only for the somewhat abnormally great stack height of 200 m. The results apply only to occasions of a small fall of temperature with height. An inversion above the chimney would make the concentration at ground-level markedly greater. Formula (*c*), which is

$$\text{maximum concentration (mgm./m.}^3) = \frac{9 \times 10^6 . Q}{h(14\,vd + H)},$$

where Q is strength of source in lb./sec., h height of stack (ft.), v speed of efflux (ft./sec.), d diameter of stack (ft.), and H rate of heat output relative to the surrounding air (B.Th.U.), gave the greatest values for the worst conditions of low height, small speed of efflux and low heat output. For this reason, and also because it is the simplest to use, Dr. Best suggests the Oak Ridge formula is the most suitable one for the stack designer.

NEW NATURE RESERVES IN ENGLAND

THE Nature Conservancy has recently established two new nature reserves—Fyfield Down, Wiltshire, and Westleton Heath, Suffolk—and in addition has acquired further land for the existing nature reserve of Yarner Wood, Devon.

Fyfield Down is one of the finest remaining tracts of unreclaimed high chalk downland in England and is probably the richest in sarsen stones, locally known as 'grey wethers', from their resemblance when seen in the distance to a flock of sheep. It is probable that the great 20-ft. sarsen stones in the circle at Avebury (weighing about 60–70 tons) were brought there from Fyfield Down nearly four thousand years ago to form the oldest important structure in Britain and one unique in Europe. Being close to Avebury, the new reserve is within one of the principal areas inhabited by prehistoric man, and the Celtic field system is one of the largest in England. There is a tumulus to the south of the fields and two others along the western boundary formed by the Ridge Way, which at this point crosses another ancient track known as the Herepath. There are also remains of an ancient village along the 700 ft. contour, the highest point on the reserve being about 830 ft. The sarsens are large blocks of sandstone apparently derived from a bed of sand which covered the site in Eocene times. Their distribution is considered to be natural, none having been erected as standing stones. They produce an effect of great botanical interest, being accompanied by pockets of acid soils, on which grow acid-loving plants such as sheep's sorrel. This is in contrast to the ordinary lime-loving plants of downland; meadow saxifrage (*Saxifraga granulata*) is abundant in the reserve. The vegetation indicates an exceptionally high humidity, and bluebells grow in the open. A varied moss flora grows on the stones. The grassland of the reserve will continue to be grazed by sheep (rabbits having been virtually eliminated by myxomatosis), and the gallops will continue to be used for training racehorses. More than sixty breeding species of birds have recently been listed at Fyfield Down, including the wheatear, grasshopper warbler and six species of tits; the hen harrier, buzzard, peregrine, quail, hoopoe, and short-eared and long-eared owls have also been observed. The present Declaration by the Nature Conservancy covers an area of approximately 610 acres, about three miles west of Marlborough, which has been leased to the Conservancy by Mr. G. E. Todd, of Manton House. Permits will be necessary for those who wish to collect specimens of animals or plants, or to visit parts of the reserve away from the footpaths. Applications for such purposes should be addressed to the Regional Officer for the South, Nature Conservancy, Furzebrook Research Station, Wareham, Dorset.

Westleton Heath straddles the road between Westleton and Dunwich. Part of this heath is already included in the Minsmere bird reserve managed by the Royal Society for the Protection of birds, and the Conservancy's acquisition of 117 acres on the eastern side safeguards the remainder up to the boundary of the Forestry Commission's Dunwich Forest, which lies between it and the sea. The heath is well known for its birds, including the stonechat, woodlark, red-backed shrike, stone-curlew, lesser redpoll and nightjar. It also has great importance as one of the few good surviving examples of the characteristic and formerly extensive East Suffolk heathlands, most of which have recently been reclaimed for agriculture or afforestation, or have been absorbed by the needs of defence. The dry sandy and shingly soil is of low fertility and is underlaid by the Westleton Beds, sands and gravel of mid-Glacial (Pleistocene) age laid down under marine conditions. It is clothed largely in heather and is crossed or bounded by roads and footpaths to which the public are asked to keep in order to reduce the fire risk and to avoid disturbing the wild life. Inquiries and applications for permits should be addressed to the Regional Officer for East Anglia, Nature Conservancy, 6 Upper King Street, Norwich, Norfolk.

Yarner Wood, near Bovey Tracey, was bought by the Nature Conservancy and declared a reserve in May 1952. A part of the wood was burnt by incendiary bombs during the air raid on Exeter in 1942, and in this section the fire killed about two-thirds of the standing trees and left others badly damaged. It was followed by a dense growth of heather, bilberry and bracken, and a plan was adopted early last year whereby part of the wood was set aside for scientific investigations into different methods of regenerating woodland, for encouraging colonization by insectivorous birds and for population studies of small mammals by the University of Exeter. Otherwise the reserve is being managed to re-establish woodland of the type which is believed originally to have been there. In order to protect and diversify the reserve, an additional twenty-eight acres adjoining the reserve and the *B*.3344 road from Bovey Tracey to Manaton have been bought by the Conservancy. Included in this addition are an interesting small alder wood and bog containing such plants as the royal fern (*Osmunda regalis*). The acquisition includes Yarrow Lodge, which is being converted to accommodate members of the Conservancy's staff working in the reserve, access to which is by permit only and must be strictly limited in order to avoid interference with the programme of scientific research. Inquiries should be addressed to the Regional Officer for the South-West, Nature Conservancy, Furzebrook Research Station, Wareham, Dorset.

BOOKS IN SHORT SUPPLY

To the specialist bookseller, the supply and prices of books which are no longer in print is a pressing problem to which there is no easy answer. In an address to the Society for the Bibliography of Natural History, C. Kirke Swann explained how the bookseller has to know the comparative scarcity of books as well as their importance to the student or collector (*J. Soc. Bibliography of Nat. Hist.*, 3, Pt. 3; January 1956). It is surprising to learn that, of those books which have been published during the past fifty years and are seemingly necessary to the student of natural history, about two-thirds of them are out of print. Demand greatly exceeds supply for such well-known books as Goodrich, "Structure and Development of the Vertebrates"; Fraenkel and Gunn, "Orientation of Animals"; Flower and Lydekker, "Introduction to the Study of Mammals"; Noble, "Biology of Amphibia"; Eltringham, "Histological Methods"; Ellis, "British Snails"; Scott, "Studies in Fossil Botany"; Seward, "Fossil Plants"; Hutchinson, "Families of Flowering Plants"; West and Fritsch, "British Freshwater Algae", and many others.

There are several reasons for this scarcity. Some editions were comparatively small and there have been no reprints; copies have been worn out through use, to say nothing of destruction and damage during two great wars; an increased interest in the subject; and comparative lack of new books to replace many of the older standard works.

The situation could be met by reprinting, but here there are several difficulties. Printing to-day is not cheap, especially if there are illustrations to be considered. Another important factor is the number of copies required. Two hundred copies or so of a number of the books would probably satisfy the demand. Reprinting in such comparatively small numbers is not economic unless the price is correspondingly high. It would often result in the prices of reprints being far higher than the present market price of the originals. Some books are rapidly becoming irreplaceable.

In discussing some of the older books the position is rather different. Editions, compared with modern books, were often very small, and in some cases extremely so, ranging from about four or five hundred copies down to less than a dozen. Another factor is the high prices at which many of the books were published, particularly if the present value of the pound, compared with, say, the year 1830, is borne in mind. Many of these older books have almost disappeared from the market and are only to be found in libraries, from which they are seldom, if ever, likely to emerge. Though quite a large number of these are now only of historical interest, they are eagerly sought after by the collector.

A NEW METHOD OF ANALYSING IONOSPHERIC MOVEMENT RECORDS

By Dr. G. L. ROGERS
Department of Physics, Victoria University College, Wellington, New Zealand

IN 1948, Gabor[1] proposed a system of microscopy by reconstructed wave-fronts which is, in effect, a two-stage image-forming process using Fresnel diffraction[2], with the option of changing wave-length half-way. Hitherto the process has been used in conversions from a short wave-length, for example, electron optical[3] or X-ray[4], up to visible light. There is no reason, however, why the method should not be used to scale down a wave-length, and this allows the optical examination of any radio wave pattern which is generated by Fresnel diffraction[5] from a sufficiently small object in an otherwise coherent main beam. The following phenomena suggest themselves as capable of investigation by this technique:

(1) Occultation of a radio-star by a sample of $F2$ region consisting of relatively small patches in an otherwise clear moving ionospheric sky[6].

(2) Ionospheric movement records when the ionosphere is largely a smooth reflector with small imperfections moving across it.

(3) Records obtained when a sensibly smooth reflector has absorbing or phase-contrast patches moving below it; for example, sporadic E below F_1, or meteor trails below E.

(4) The need for a small object in an otherwise coherent beam may be removed, by supplying a 'coherent beam' artificially from elsewhere, after the Gabor and Goss[7] 'round the square' interferometer. In the case of radio signals, this is relatively easy, as a signal can be taken from the transmitter's master oscillator, suitably attenuated, and fed into the receiver, where it combines with the downcoming signal in accordance with the well-known 'coherent demodulator' technique[8]. In this case, the signal passed direct from the transmitter may conveniently be two or three times the strength of the maximum reflected signal, so that the phase of the sum-term never departs too far from that of the larger signal. Alternatively, the analogy with the Gabor and Goss interferometer may be made complete by replacing the optical 'quadrature prism' by an analogous radio network consisting of two 'coherent demodulator' receivers, one working directly from the transmitter's master oscillator, the other from this signal after passing through a 90° phase-shifting network[9]. The outputs from *both* receivers must be recorded, and may later be combined optically in a Gabor and Goss interferometer. This later technique removes all restriction on the degree of roughness in the ionosphere which may be investigated.

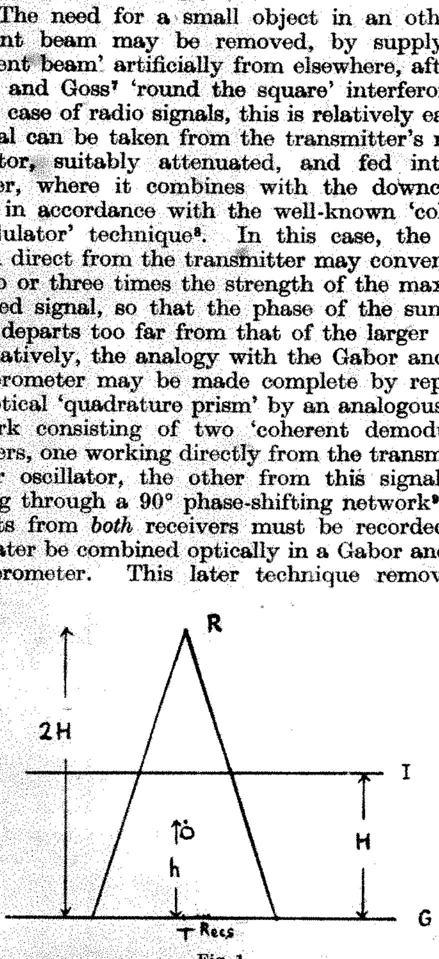

Fig. 1

A preliminary investigation of this technique has now been undertaken. The radio arrangement is shown in Fig. 1. Here we take the ionosphere provisionally as a good reflector, a point we can check later by reconstructing an 'image' of it. The reflexion R of the transmitter T in the ionosphere, I, may be regarded as a point source of coherent radiation diverging from R, and giving rise to a diffraction pattern of the object O, which will travel over the ground as the projection of O's motion. It is shown elsewhere[2] that this diffraction pattern is characterized by a 'focal length', f_r, given by:

$$f_r = \frac{2Hh}{2H-h} \tag{1}$$

When the record is converted into a variable-density photographic plate[10], it is found to have a visual focal length, f_v, in a visual wave-length λ_v, given by

$$f_v = \left(\frac{\lambda_r}{\lambda_v}\right)\left(\frac{d}{T.v_g}\right)^2\left(\frac{2Hh}{2H-h}\right) \tag{2}$$

where λ_r is the radio wave-length, d the distance on the photographic plate corresponding to the time marks on the records, T the time interval between these marks, and v_g the velocity of the diffraction pattern over the ground. The actual velocity of the object, at height h, is

$$v_h = (2H-h)\, v_g/2H$$

To test the method, use was made of existing Dominion Physical Laboratory records, obtained on 2·404 Mc./s. (approximately 125 metres) with a pulse length of about 70 µsec. and a receiver gate of 150 µsec. at 100 pulses per sec. from three aerials arranged according to the Mitra[5] pattern at a spacing of 100 yd. The signals were separated, and each was converted into an equivalent variable-density track[10]. These tracks were then mounted in register and rephotographed, the north aerial track being repeated top and bottom to assist in getting a vertical line. The resultant hologram (Fig. 2a), which was just over 1 mm. wide and about 6–8 mm. high in all, was put on to the optical bench and a number of values of f_v were found visually, and confirmed by photography. The photographs show a black line developed in the 'image' of each track: each line is in an ideal case a one-dimensional image of the object O. Owing to the time delay in passing over the different aerials, these reconstructed black lines are laterally displaced from track to track, and the corresponding time-interval may be deduced by measuring the shift. v_g may then be deduced at once, using the analysis of Mitra's paper[5]. A particularly good example is shown in Fig. 2b and less obvious cases in Figs. 2c and d. It is believed the latter may be an 'image' of the ionosphere itself, but the evidence is not fully conclusive.

Attempts to deduce v_g are subject to some uncertainty, because of the small scale of the hologram necessary to get a reasonably small f_v. Thus Fig. 2a was originally at a scale of about 12µ per sec. A better plate-measuring microscope than available

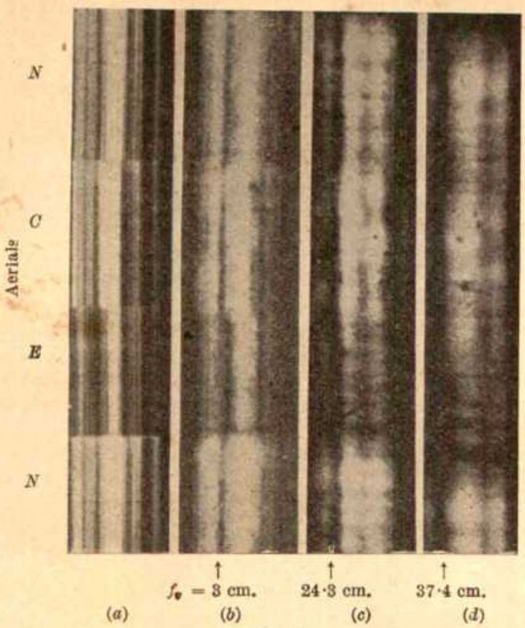

Fig. 2

here might have improved matters, and the use of a longer recorded track would also have assisted, by increasing the resolving power, and reducing the line-width. Case 2*b* is the most accurate; it corresponds to an object moving at 10–15 metres/sec. at a height of 100–300 metres. It is thus abundantly clear that objects far below the ionosphere can make significant contributions to ionospheric movement records.

It will be seen from equation (2) that if v_g is obtainable, everything is known but h; and hence the height of the object may be deduced. Unfortunately, the expression contains a term in v_g^2, and is thus subject to considerable uncertainties. It has, however, an important advantage over traditional methods of analysis in that h is otherwise quite indeterminate.

Fig. 2 also brings out an important point, namely, that most ionospheric movement records are composite, and give information relating to quite different levels. So far as is known, diffraction microscopy constitutes the only method of analysis which gives even partial height discrimination.

In routine use, direct recording of the three signals as variable-density tracks is essential, as the labour of conversion[10] from present variable-area tracks is prohibitive on a large scale. No very great linearity in the recording system is required. Experiments on such direct recording are being considered. On the optical side, methods are being developed to enable the effective visual foci and lateral shifts to be measured rapidly.

For those interested in the mathematics of correlation, it may be noted that 'reconstruction' in a diffraction microscopy apparatus is equivalent to correlating the observed radio diffraction pattern with a wave which is a diametral section through a Newton's ring system, the scale of the latter being varied by moving up or down the optical bench. A sharp peak is expected on the correllogram when the scale of the Newton's ring wave corresponds to one of the visually determined 'image' planes. At the same time, the effects of other phenomena, at different heights, are weakened, and hence the movement velocity obtained by diffraction microscopy is expected to be more reliable than that obtained by other means. The usefulness of this technique will thus be apparent.

I am indebted to the Director of the Dominion Physical Laboratory for permission to use ionospheric movement records obtained by Mr. G. J. Burtt and his staff, also to Prof. G. A. Peddie of this Department for help and encouragement.

[Sept. 26

Note added December 9. Since the above was written, a Dakota aircraft has been sent up on an ionospherically quiet day and a one-dimensional 'image' of it has been recovered by diffraction from one of the aerial records obtained. This confirms a tentative identification of the 100–300 metre object as probably a light aircraft.

LOCOMOTION OF WORMS

A VERY little naked-eye observation shows that both the usual text-book account of the locomotion of worms (largely based on the work of Friedländer[1]) and the more recent papers by Gray[2] and Gray and Lissmann[3] are inadequate descriptions of how a worm moves.

My interest in the subject was first aroused by the accidental observation, in 1931, that a worm could move on the vertical surface of a sheet of polished tin. I have several times since then seen a worm moving upwards on a vertical surface of glass, such as the side of a beaker. So far as I am aware, no mention of this ability has appeared in the scientific literature, but an account of a worm crawling up a window-pane was given some years ago by an anonymous correspondent in *The Times*[4]. It is clear that such movement cannot be explained by the usual description.

I have observed worms moving on various surfaces, smooth and rough, dry and wet, and in glass and plastic tubes and in other forms of artificial burrows. The species were not determined, but there seems to be no great difference between *Lumbricus* and *Allolobophora*, and as there have certainly been several species and probably other genera among my material, it is probable that locomotion is similar in all the Lumbricidae. The chief points of amplification or correction of the published accounts are the following.

(1) The segments which are moving forwards are often raised a little above the surface; this lifting is increased and unnatural when the worm is on some-

thing such as absorbent paper, which tends to dry it, but may also be seen at other times. From the physical point of view, raising the body must assist locomotion by reducing the resistance to forward motion while increasing that to backward slip.

(2) In spite of (1), there is often much backward slip on a smooth surface, such as glass, and even on quite rough paper. This is especially noticeable when the tail elongates; it then moves backwards, and only in the subsequent contraction of the longitudinal muscles does it move forwards. Slip is also seen (and heard) when the anterior segments shorten and move backwards.

(3) The contraction waves often do not pass more than half-way down the body; if they do not go to the end, the tail is dragged passively forward.

(4) The chætæ are probably of little assistance in locomotion on a surface. So far as I have observed, they are never extruded unless the longitudinal muscles of their segment contract, but it is quite possible for this contraction to occur without extrusion of the chætæ, and if segments remain contracted the chætæ may be gradually withdrawn. In one preparation of the anterior eight segments of a worm, the chætæ several times remained erect after the longitudinal muscles had extended. In extrusion, the chætæ of the anterior part of the body are directed slightly backwards, those of the middle segments are directed radially, with some irregularity, and those of the last twelve or so segments are directed strongly forward. These posterior chætæ are longer than the others. In normal locomotion only the chætæ of the first dozen or so segments are extruded.

(5) Large 'steps' can be taken by the worm on a smooth surface such as glass only if the extreme anterior end is first placed in contact with the surface, and I now have good visual evidence that this end is acting as a sucker. If the worm is observed from below, one can see that the extreme anterior end is pressed against the glass, the peristomium is pressed around it in a ring, and then the central parts of the anterior end are withdrawn from contact with the glass. I have not been able to see any action of the pharynx in this process, as described by Dr. Roots in the following communication, and I think that it is the whole prostomium which is withdrawn. Whatever the exact mechanism, the resulting decrease in pressure anchors the worm, and if the opposing resistance becomes too great, the sucker can be seen to leave the glass with a jerk. If a worm is moving on a stretched 'Cellophane' sheet, it can be seen to suck this inwards as it touches down. This is especially obvious when it is taking big steps. That worms could drag stones and other flat objects by suction was known to Darwin[5], but he did not know that the same method was used by the worm to drag its own body.

(6) When the worm is strongly stimulated at the anterior end, and sometimes when that end is without support, there is backward locomotion of a generally similar type to the normal. The tail end is strongly flattened and the posterior chætæ thrust out; as has been said under (4), these point forwards. It is doubtful if backward locomotion on the surface is ever of much importance in Nature, but it is this reflex which anchors the worm in its burrow and makes it so difficult to pull out. It is not a matter of overcoming a frictional resistance, as described by Chapman[6], but of breaking a system of interlocked structures. Either the soil, or the chætæ, or the worm, must break, and usually it is the last.

(7) I suspect that both the anus and the cut surface of a worm may on occasion act as suckers, but I have no certain evidence that they do.

(8) Fluid sometimes leaks from the dorsal pores, both spontaneously and as a response to prodding. This to some extent discounts the theoretical discussion of Chapman[6].

(9) Movement along a tube is carried out largely by a technique similar to that known to rock-climbers as 'backing up', and it is reasonable to suppose that movement in a burrow or in loose soil is similar. For the initial stages of burrowing, where alone anything can be seen, this has been described by Darwin[5] and Newell[7], and I have confirmed their observations.

(10) When a worm in a tube meets a plug made of soil, it generally tries to get through by the technique just described. If it fails, it extrudes the pharynx to a length of two or three segments and sucks in a mouthful of soil, and continues until a hole is made. Sometimes, presumably when in subjective terms it is hungry, without waiting to try to force its way through, it begins sucking as soon as the prostomium touches the soil, but I have never seen a worm pause to eat soil once its anterior end had emerged beyond the plug. I have once or twice seen the pharynx everted before contact with the soil, but only when the prostomium is very near it. This suggests that the worm is reacting to the sensation of smell. Occasionally a little soil is sucked into the mouth without eversion of the pharynx.

(11) In a tube which is only slightly wider than the maximum diameter of the worm, the animal can completely reverse itself by going through a hairpin curve.

(12) When the worm is in a tube, it has a strong tendency to become quiescent; in this state it does not move, and even strong stimuli induce nothing but contraction of the longitudinal muscles, with no locomotion.

[7] Newell, G. E., *J. Exp. Biol.*, **27**, 110 (1950).

The absence of an eversible pharynx is given by at least one well-known text-book as a character which distinguishes the Oligochaeta from the Polychaeta; but the eversion of the pharynx can readily be observed in some of the Lumbricidae. It is strange that Darwin, who made extensive observations on earthworms, does not record this fact.

While observing earthworms in soil between vertical glass plates, I noticed that in *Lumbricus terrestris* and *Allolobophora terrestris* forma *longa*, the pharynx is everted during the preliminary testing of the soil before burrowing, and when the worm is eating its way through compact soil. The pharynx is also repeatedly everted on to leaves before they

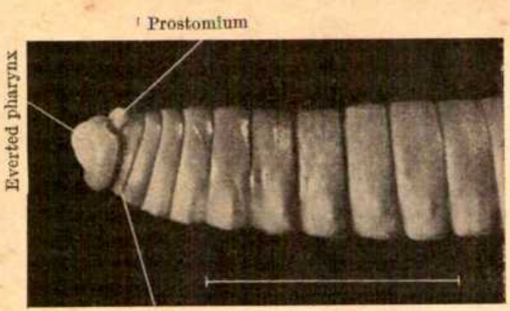

Fig. 1. *Allolobophora terrestris* f. *longa* with pharynx everted

are dragged to the burrow. Darwin[1] records that leaves taken from burrows (and in one case leaves still attached to the plant) are found to have been moistened by an alkaline secretion. It is possible that the secretion may be deposited by the everted pharynx; alternatively, the pharynx may be 'tasting' the leaves. The everted pharynx is shown in Fig. 1, which is a photograph of the anterior end of a specimen of *Allolobophora terrestris* f. *longa* which was fixed while the pharynx was everted.

The pharynx may also function as a sucker, as described by Darwin[2] but without record of its being used for the movement of the worm itself. Anyone who has put some small earthworms into a beaker and left them uncovered knows that after a time they will be found on the bench. Obviously movement up a vertical glass surface cannot be brought about by the mechanism usually described, and the method used is as follows. The anterior end (about nine to twelve segments) is extended upwards, the peristomium and the ventral portion of the prostomium are pressed against the glass, and at the same time the buccal mass and pharynx are pushed forwards and then withdrawn so that suction is developed. Often the pharynx is extruded before contact is made with the glass, so that it is the first to touch the glass. The extended segments then contract, a wave of contraction passes backwards and the body of the worm is dragged upwards. Downward slip is retarded by viscous forces, or in very small worms is prevented altogether by surface tension. Except for the most anterior segments, the ventral surface remains in contact with the glass. I have seen this method of movement in *Allolobophora caliginosa*, *Dendrobaena subrubicunda*, *Eisenia foetida* and *Lumbricus rubellus*.

I have not seen the prostomium used in the way described by Mr. Yapp in the preceding communication, but as the morphology of the anterior end varies from species to species, the method used may also vary in detail while the principle of suction remains the same.

Observations of worms in narrow vivaria have also confirmed that the method described for the initial stages of burrowing[3] (alternate attenuation and expansion of the anterior end) is also used during movement within the burrow and through loose soil.

PHYTOPLANKTON AND HYDROGRAPHY OF THE PACIFIC PART OF THE ANTARCTIC OCEAN

By GRETHE RYTTER HASLE
Institutt for Marin Biologi, Avd. B, University of Oslo

THE Norwegian South-Sea Expedition (the *Brategg* Expedition), visiting the Pacific section of the Antarctic Ocean in the summer season 1947–48, collected quantitative phytoplankton samples from seven to eight depths at about sixty stations. From the upper 50 m. net samples were also taken. The samples from the stations along the 120th West meridian have been worked up: stations 33–44, between lat. 57° 22′ and 68° 13′ S., taken January 26–31; station 17, lat. 62° 02′ S., taken December 30. The quantitative samples were analysed by the sedimentation method.

At these stations the hydrographic data demonstrate a marked difference in the upper 200 m. between the sub-Antarctic and the Antarctic zones. The surface layers were in both zones about 50 m. deep; in the sub-Antarctic zone the temperature was 3°–5° C., increasing from south to north, the salinity was 34·0 per mille, σ_t was 26·9–27·1; in the Antarctic zone the temperature was between $-1°$ and $+1°$C., the salinity 33·4 per mille and σ_t was 26·8–26·9. Below the sub-Antarctic surface layer, the Antarctic intermediate water was characterized by having a temperature minimum located somewhat deeper than the water masses sampled for phytoplankton. Below the Antarctic surface layer the winter-water was found to be colder, saltier and heavier than the upper layer (temperature $-1°$ to $-2°$ C., salinity 34·0 per mille and σ_t 27·4). This winter-water was found between 50 m. and 100 m. The Antarctic Convergence was in December located at about lat. 62° S., and in January at about lat. 61° S. This shift influenced the hydrographical conditions at the two stations worked at the same position: thus station 17 in December belonged to the sub-Antarctic zone, whereas station 38 in January lay in the Antarctic zone.

These hydrographic features are reflected in the distribution of the phytoplankton. The Antarctic zone was far richer than the sub-Antarctic in the total number of cells per litre at each station, and especially so for the diatoms. As a rule, a station in the Antarctic zone had about ten times as many cells as a station in the sub-Antarctic zone. Within the two zones the fluctuations were very small and the increase from the sub-Antarctic to the Antarctic zone at the Antarctic Convergence was most conspicuous (see stations 37 and 38 in Fig. 1).

The vertical distribution differed in the two zones (Fig. 1). In the sub-Antarctic zone, with its com-

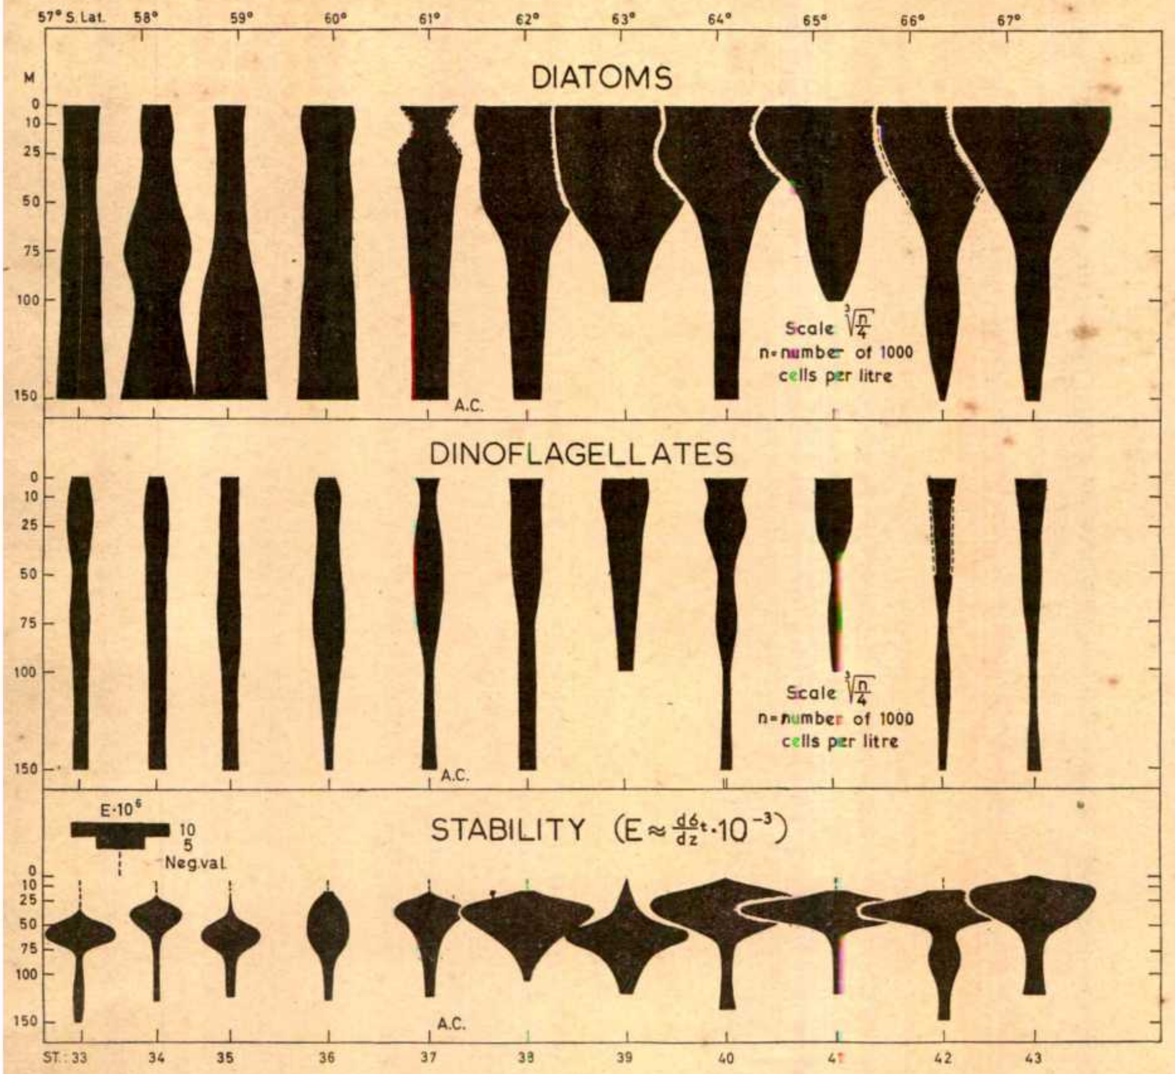

Fig. 1. Vertical distribution of the phytoplankton. AC, Antarctic Convergence. Depths (ordinates) are plotted against positions and stations

paratively low stability, the distribution with depth was approximately even, although at some stations populations were larger at 100 m. and 150 m. than at 0 m., mainly due to the abundance at the lower levels of resting spores of the diatom *Chaetoceros neglectus*. In the Antarctic zone, with its pronounced stability, the large phytoplankton populations were confined to a surface layer of 25–50 m.

In some of the species the Antarctic Convergence acts as a boundary in their horizontal distribution. This is exemplified by the following species.

Coccolithus huxleyi (Lohmann) Kamptner, the only coccolithophorid recorded from the Antarctic ocean, occurred only in the sub-Antarctic zone, at stations close to the Antarctic Convergence.

Thalassionema nitzschioides Grunow is an example of a diatom from the sub-Antarctic zone the numbers of which decreased from December to January. The prevalence in the deeper layer in January also indicates that the vegetation period of this diatom was then at its close.

Nitzschia closterioides n. sp. is an example of a diatom from the Antarctic zone which was not entirely restricted to this zone. The populations in the sub-Antarctic zone were, however, rather small compared with the Antarctic zone, even at the beginning of the season (station 17).

Peridinium applanatum Mangin, the only dinoflagellate recorded in relatively great numbers, was strictly confined to the Antarctic zone.

Chaetoceros neglectus Karsten cannot be characterized as belonging to either the Antarctic or the sub-Antarctic zone. In January no cells were recorded from the sub-Antarctic zone, whereas in the Antarctic zone the populations were rather large. In December, however, the cell numbers in the sub-Antarctic zone were as large as in the Antarctic zone a month later. The increase seems to have started to the north in the sub-Antarctic zone at the beginning of the season, and in January the maximum occurred in the middle of the Antarctic zone, at station 41. This impression of a north to south sequence in the increase of the population is also corroborated by the occurrence of resting spores in the deeper layer of the sub-Antarctic zone in January, and by the fact that numbers of this species showed a sudden increase, not at the Antarctic Convergence, but to the south of this region.

New Determinations of the Velocity of Light

IN 1953 the Ordnance Survey was asked by the U.S. Army Map Service to test its Bergstrand *AGA* geodimeter. This was done by using it to re-measure the two bases of the recently completed primary re-triangulation of the United Kingdom[1]. From these measurements it was possible to deduce a new value for the velocity of light *in vacuo*. Recently, the Ordnance Survey has received the account of a fresh determination by R. Schöldström[2] on the Öland base line in Sweden which gives a value which agrees very closely with that deduced from our results. The comparison between the generally accepted value determined by Bergstrand in 1950[3] and the three recent determinations is as follows:

Bergstrand, Öland base 1950 (5,402 metres): 299,793·1 ± 0·2 km./s.

Ordnance Survey, Ridge Way base 1953 (11,261 metres): 299,792·4 ± 0·11 km./s.

Ordnance Survey, Caithness base 1953 (24,829 metres): 299,792·2 ± 0·13 km./s.

Schöldström, Öland base 1955 (5,402 metres): 299,792·4 ± 0·4 km./s.

Both bases used for the Ordnance Survey determination had earlier been measured by 'Invar' tape in catenary: the Ridge Way base twice, in 1937 and 1951, and the Caithness base once in 1952[4]. The two measurements of the Ridge Way base carried out at different times, using different tapes and under very different conditions, differed by 1 in 1,700,000. The forward and back measurements of the Caithness base differed by 1 in 1,270,000. The tape-measured lengths of both bases are therefore very accurate. Of the two the Ridge Way length is probably the more accurate. It is the weighted mean of two independent measurements, and the base was sited more favourably than at Caithness, where part of the line traversed difficult boggy ground.

The Ridge Way base in Wiltshire runs from White Horse Hill (altitude 858·1 ft.) to Liddington Castle (altitude 914·7 ft.) and for the greater part of this distance the light path is 150–250 ft. clear of the ground. The Caithness base runs from Warth Hill (altitude 408·7 ft.) to Spital Hill (altitude 581·6 ft.) and the height of the light path above ground varies from 0 to about 500 ft. Temperature, barometric pressure and relative humidity were observed at the terminals and the means of the two terminal values used to correct each geodimeter observation. The observations were carried out in variable weather over a number of nights at each base.

A filter was used passing light with a group wavelength (Λ) of 5580 A. The formula used for obtaining the refractive index μ_G of the wave group in ambient conditions was:

$$\mu_G = 1 + \frac{\mu_g - 1}{1 + \alpha t} \times \frac{p}{760} - \frac{0{\cdot}000000055e}{1 + \alpha t}$$

in which t is temperature in degrees centigrade, p is atmospheric pressure in mm. of mercury, e is vapour pressure in mm. of mercury, α is the coefficient of expansion (0·00367), and μ_g is the group refractive index of dry air at 0° C., 760 mm. pressure and 0·03 per cent of carbon dioxide calculated using the formula

$$\mu = 1 + \left(2{,}876{\cdot}4 + \frac{16{\cdot}288}{\Lambda^2} + \frac{0{\cdot}136}{\Lambda^4}\right) 10^{-7}$$

for monochromatic light[5].

Two modulating frequencies (f_1 and f_2) were used, the mean of the observations on both frequencies constituting one complete measurement. The frequencies of the two oscillators had been determined by the U.S. authorities before the dispatch of the instrument and were checked by the National Physical Laboratory. The comparisons were as follows:

f_1	U.S.	June 1953	9,999,944 c./s.
	N.P.L.	Aug. 7, 1953	9,999,932 c./s.
	N.P.L.	Oct. 12, 1953	9,999,945 c./s.
f_2	U.S.	June 1953	10,099,854 c./s.
	N.P.L.	Aug. 7, 1953	10,099,855 c./s.
	N.P.L.	Oct. 12, 1953	10,099,853 c./s.

For the computations the American figures were accepted.

The constant of the geodimeter was also verified at the National Physical Laboratory by a direct method using the 50-m. mural base normally employed for standardizing geodetic surveying tapes. The value obtained confirmed that obtained by the makers of the geodimeter, who use a different method.

Table 1 gives a summary of the important data relating to the determinations of the velocity of light by means of the geodimeter at the two bases in the United Kingdom. The rejected observations were those taken under unfavourable conditions (for example, unpractised observer, very still air).

Because of the probable greater accuracy of the Ridge Way base-length and the greater variation in height of the Caithness light-path, the Ridge Way value, 299,792·4 km./sec., is the more reliable.

It is clear from Schöldström's account that his determination is also a very strong one. In arriving at his error limits, he has taken into account the uncertainty due to errors in his accepted values for temperature, pressure, humidity, colour and frequency. The limits given for the Ordnance Survey values are simply the mean square errors deduced

Table 1

Period 1953	Line: geodimeter station first	Length from base measurement (air distance)	No. of obs.	Root mean square errors		Remarks
				Single observation	Mean	
July 5–29	White Horse Hill Liddington Castle	11,260·677 ± 0·003 m.	14	0·010 m.	0·003 m.	3 observations rejected
Aug. 13–24 Sept. 20 to Oct. 5	Warth Hill Spital Hill	24,828·626 ± 0·010 m.	16	0·030 m.	0·007 m.	Of the 23 observations, 7 were rejected, 3 from the first visit and the remainder from the second

from internal evidence and are not therefore strictly comparable.

Electron Microscopy and Radioautography as Coupled Techniques in Tracer Experiments

CONSIDERABLE progress has already been made towards high resolution in radioautography, and good results have been obtained by various workers with the Ilford peeling film technique of Pelc[1], the *NTB* stripping method of Boyd[2] and the 'wet-process' system of Gomberg[3]. Lately, I have shown[4] that, by using thick layers of nuclear emulsions (300μ), and avoiding background effects by placing the specimens in a coal mine at a depth of 600 metres[5], it is possible to follow the β-particle tracks to their origin and obtain a one-micron resolution.

Films of the sensitive emulsion may be made thin enough to allow observation in the electron microscope, thus adding greatly to the resolution. The process is as follows. Microscope slides, specially selected for freedom from radioactive contamination, were covered with a layer of collodion or 'Formvar'. In the experiment described here, the specimens were nuclei extracted from tumour tissues and labelled *in vitro* with cobalt-60 (β-ray, 0·3 MeV.). They were placed on the collodion and covered with a thin layer of Ilford *G5* nuclear emulsion, obtained by melting the gel at 55° C., as in the usual procedure, and diluting it with water to the proper consistency. The slides, after drying, were placed for exposure in a thick-walled lead box. As a proportion only of the β-particles are likely to be emitted in the plane of the sensitive layer, the necessary exposures are longer than in the thick-layer method previously employed.

The slides were developed in Ilford *P.Q.* Universal developer, cleared in hypo within 20 sec. and fixed for 2 min. After washing, the double layer of collodion-gelatine was lifted from the slides without difficulty and mounted in the electron microscope. The accompanying electron micrograph (Fig. 1) shows the tracks emitted by four single nuclei at a magnification of 2,000 (reduced from the original magnification of 6,000).

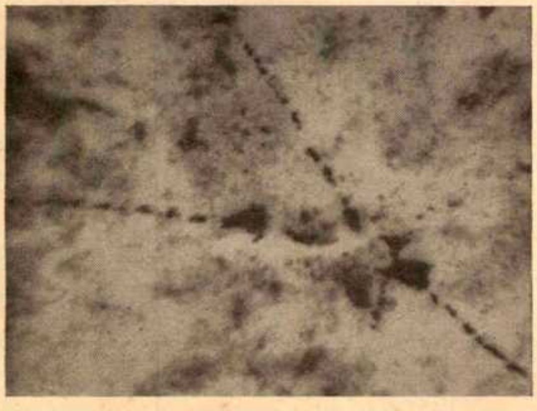

Fig. 1. Electron micrograph of β-ray tracks emitted by tumour nuclei labelled with radioactive cobalt-60. × 2,000

This new technique, successful for the particles of cobalt-60, of energy 0·3 MeV., is likely to be of great value in the case of the soft radiation of carbon-14, as the grains of the tracks are close enough to allow a very high magnification.

So far the method has been applied to isolated cells and cell nuclei, but it is hoped to extend it to ultra-thin tissue sections.

I am indebted to Prof. J. Sayers, of the Electron Physics Department, University of Birmingham, for facilities, and I wish to acknowledge the skilled technical help of Mr. C. C. Newton. This work was done under a grant from the British Empire Cancer Campaign, London.

Zinc-deficiency of *Hevea brasiliensis* as a Predisposing Factor to *Oidium* Infection

INFECTION of the *Hevea* rubber tree by *Oidium heveae* is common in Malaya but is not regarded as a major pathological problem; in Ceylon, however, the fungus can produce serious loss of crop yields and the problem is of economic importance[1]. *Oidium heveae* is most prominent in Malaya at the time of refoliation after 'wintering' of the trees, when it may cause a secondary leaf-fall. It is only at this time that *Oidium* is found on leaves exposed to full sun. Throughout the year it may be found on young plants but only when these are shaded, and then never sufficiently seriously to cause defoliation. A small number of poorly developed colonies of *Oidium heveae* are usual on the leaves of plants grown in our plant-house[2] as the glass and framework of the house provide light shade. During the study of the micronutrient-deficiency symptoms of *Hevea brasiliensis* grown in sand culture within this house, a striking relationship between the susceptibility to severe *Oidium heveae* attack and the zinc status of the plants was noticed. This relationship was not noted for the copper- or molybdenum-deficient plants grown simultaneously and in the same environmental conditions as the zinc-deficient plants. Our observations were thus made on plants grown under glass and were derived from one experiment only; the results, however, were so well marked that their significance should be quickly tested and evaluated in countries where *Oidium heveae* attack is of major concern.

'Selfed' seeds of clone Tjirandji 1 were sown in sand which had been rigorously purified by boiling with hydrochloric – oxalic acid mixture, and which was contained in 'Pyrex' glass vessels. Two types of nutrient, all nitrate nitrogen or part nitrate- part ammonium-nitrogen, were supplied to the seedlings;

but as this did not influence the main result described below, it will not be mentioned further. The nutrients were freed from zinc by subjecting them to phosphate adsorption followed by dithizone extraction, essentially as described by Hewitt[3], whose procedure was also employed for the purification of the ferric citrate. Zinc was supplied in the 'complete' nutrient solution at a concentration of 0·065 part per million; this was the only factor wherein the 'complete' cultures differed from the zinc-deficient cultures. Water which had been purified by passing through ion-exchange resins was used throughout.

Three months after sowing, severe symptoms of zinc deficiency occurred; these included rosetting, production of narrow, strap-like, young leaves with wavy margins, chlorosis and malformation of young laminæ, death of growing points, production of numerous lateral shoots and severe stunting (Fig. 1). That these symptoms were truly those of zinc deficiency was proved by the recovery of the affected plants when supplied with 'complete' nutrient. Plants which had received the 'complete' nutrient solution throughout the experiment grew rapidly and well and remained comparatively free from disease; but from the sixth month onward, the zinc-deficient plants became severely infected with *Oidium heveae*. The heavy infection was confined to those parts of the plant formed in the absence of a sufficiency of zinc.

Abnormally large and heavily sporing colonies of *Oidium heveae* were found on the laminæ (Fig. 2); the fungus also completely enveloped the growing tip of the severely deficient plants and some of the newly formed leaves fell. The 'complete' nutrient plants, grown adjacent to the zinc-deficient plants, showed only the odd, feebly developed colony usual on all plants in the plant house.

An analysis of plants sampled six and a half months after sowing showed that the 'complete' nutrient plants contained eight to ten times as much zinc per plant as the zinc-deficient ones.

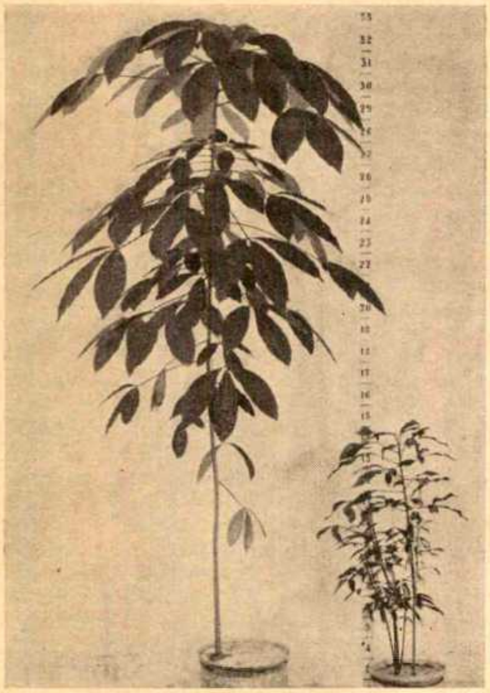

Fig. 1. Complete nutrient plant (left); zinc-deficient plants (right). One scale division equivalent to three inches. Eleven-month old seedlings

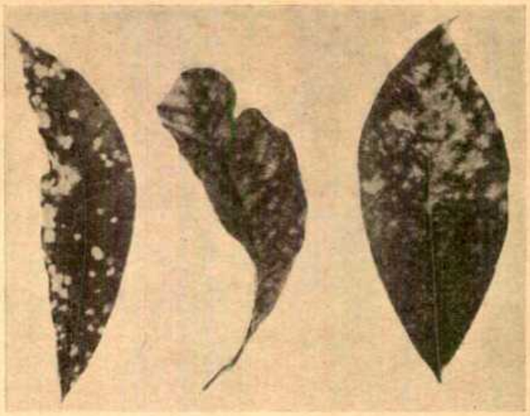

Fig. 2. Zinc-deficient laminæ heavily infected with *Oidium heveae*. Top surface, two laminæ on left; bottom surface, lamina on right. ⅗ nat. size

It seems likely that without a sufficiency of zinc the rubber plant is unable to produce enough of a certain metabolite which confers some degree of resistance to *Oidium heveae* attack. We plan to repeat our experiment in order to determine whether substances other than zinc can confer resistance. In the meantime, it appears possible that in some areas the prevalence of *Oidium heveae* may be accounted for by a lack of zinc available to the plants.

Reduction–Oxidation Level of Soils

SEVERAL attempts have been made to determine the redox potentials of soils by inserting a suitably treated platinum electrode into the soil suspension and measuring the e.m.f. against a reference electrode; but from a strictly physico-chemical point of view one cannot speak about well-established redox potentials in soils, which are derived from experimental data. To avoid these difficulties, the use of the empirical term 'redox level' is suggested, thereby giving an expression for the mean reducing or oxidizing activities in dry soil samples.

If a soil is treated with a solution containing the reversible redox system potassium ferrocyanide and ferricyanide, the e.m.f. of a platinum electrode measured against a reference (calomel) electrode in the soil suspension will be different from the potential in the pure solution. These differences, ΔE mV., may be correlated with the reducing or oxidizing properties of the soil. By treating the same soil with solutions containing potassium ferro- and ferricyanides in different ratios, all buffered with 1 M ammonium acetate, and plotting ΔE found against the E values of the pure solutions, one gets an S-shaped curve, which intersects the E-axis in the point E'. This point corresponds to a solution that does not change its redox potential in contact with

Table 1

Soil	E' (mV.)	Total Mn (p.p.m.)	*p*H in 1 *N* KCl quinhydrone	*p*H′
1	389	45	5·1	5·08
2	486	123	4·8	4·06
3	456	152	5·0	4·73
4	483	165	6·8	6·82
5	508	328	4·3	3·70
6	511	395	5·3	5·32
7	566	695	5·5	5·53

the soil; thus it may be regarded as an expression for the redox level of the soil.

In seven totally different Danish soils the following measurements have been carried out: 10 gm. air-dried soil was shaken for 1 hr. at room temperature with 50 ml. of ferrous-ferric-cyanide solutions, all buffered with 1 *M* ammonium acetate. The concentration of potassium ferro- and ferri-cyanide varied between 10^{-4} and 10^{-2} mole/l., and the E values measured were all referred to the normal hydrogen electrode. Total manganese was determined by ignition of the soil and subsequent treatment with hot hydrogen peroxide solution containing nitric acid. Manganese was determined colorimetrically as potassium permanganate in the filtrate. Table 1 and Fig. 1 show a linear correlation between the total manganese content and the values of E', indicating that with increasing content of total manganese the redox level increases proportionally.

The values of ΔE were quite reproducible, but they could be caused by either absorption or precipitation of the iron-cyanide ions in the soil suspensions instead of merely by redox processes as indicated by:

$$\mathrm{Fe(CN)_6^{----}} \rightleftarrows \mathrm{Fe(CN)_6^{---}} + e^-.$$

In the strongly buffered solution containing acetate and iron cyanide ions in a ratio of at least 100 : 1, extensive absorption of the iron cyanide ions is not likely to occur. Several heavy metals might precipitate the iron cyanide ions, but in the presence of, for example, 3·75 p.p.m. zinc, the maximum precipitation cannot exceed 0·1 per cent of the total in the case of ferrocyanide, which would cause an increase of 3 mV. in the e.m.f. measured. This difference is only about of the same order of magnitude as the experimental error. For soils rich in iron, one would expect precipitation of ferro- and ferri-cyanide compounds, but tests have shown that in the strong acetate medium iron ions are blocked as acetate complexes.

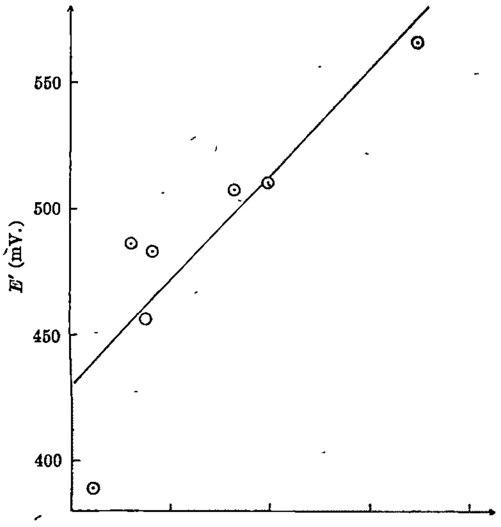

Fig. 1

A soil very rich in iron oxides was found to give $\Delta E = 0$ for a ratio of ferri- to ferro-cyanide of 13·8. This soil was shaken with solutions containing iron cyanides in this ratio, the total concentration of which was varied by ten-fold dilution, while the ammonium acetate concentration was kept constant at 1 *M*. This experiment showed that ΔE still remained close to zero, that is, E' is independent of the dilution.

The same principle has been used in connexion with *p*H measurements in soils. 10-gm. portions of the seven soils were shaken with 100 ml. of 1 *M* potassium chloride solutions buffered with citric acid and disodium hydrogen phosphate in a total concentration of about 0·01 mole/l. These solutions had a *p*H ranging from 2·8 to 7·3. After 1 hr., the *p*H of the suspensions was determined by glass-electrode measurements, and the differences (ΔpH) between the *p*H of the suspensions and those of the pure buffer solutions were plotted against the *p*H of the buffer solutions. Here again an *S*-shaped curve was formed, and the intersection with the *p*H-axis at the point *p*H′ indicated a buffer solution of such a composition that it did not change its *p*H by contact with the soil. Therefore *p*H′ is identified as the *p*H of the soil, here measured with quinhydrone in 1 *N* potassium chloride soil suspension, and as shown in Table 1 this is true for four of the seven soils having a *p*H greater than 5. The discrepancies are probably due to complex formation with trivalent metals, for example, ferric or aluminium ions.

By these methods it might be possible to study the concept of redox capacity as well as buffer capacity, and they enable the study of problems such as the ageing of the soil during storage or changes in exchangeable manganese during transfer of the soil from natural conditions to the laboratory. Investigations are being continued and a more detailed publication will appear.

Occurrence and Nature of an Amœba Excystment Factor produced by *Aerobacter* sp.

ALTHOUGH an excystment factor potentiating the emergence of trophozoites from their resting cysts in Protozoa has long been postulated, there has so far been no convincing experimental evidence of its existence. A critical appraisal of previous work[1-4] has revealed that the factor has variously been attributed to hypo- and hyper-tonicity of the medium, low oxygen tension, change of *p*H, reducing agents, presence of enriched nutrient media, change of temperature, etc. Earlier workers in this field do not appear to have adequately recognized the risk of extraneous infection inherent to such experiments, particularly when nutritionally rich and highly susceptible media, such as 'Difco' yeast extract, are examined for the presence of this factor[5]. Unless absolutely aseptic conditions are maintained in the course of experiments, the results will remain open to doubt.

Crump[1] showed that excystment in *Amœba* Z, (*Didascalus thorntoni*; Singh[6]) took place without the presence of bacteria, while *Amœba* 4 (*Schizopyrenus russelli*; Singh[6]) excysted only in the presence of certain bacteria (*Aerobacter* sp. and 4036). She suggested that the two species of bacteria produce in the medium some material that induces excystment in *S. russelli*. In view of Crump's[1] findings, it was of interest to secure an experimental proof of its occurrence and elucidate the nature of the factor produced by *Aerobacter* sp., Strain 1912; Singh[7]. As bacteria and amœbæ live in close association in human and animal intestines, a detailed study of amœba excystment factor or factors, produced by *Aerobacter* and other intestinal bacteria, would be of considerable significance for a more effective approach to the problem of amœbic dysentery.

Large numbers of mature cysts of *S. russelli* (see Singh[6] for culture methods) produced on *Aerobacter* sp. on non-nutrient agar (2·5 per cent agar, 0·5 per cent sodium chloride; *p*H 6·8–7·0) were treated with a mixture of penicillin (4 units/c.c.) and streptomycin (4 μgm./c.c.) solution for about 24 hr. at room temperature (25°–26° C.). They were washed by centrifugation with 0·85 per cent sodium chloride and tested for their sterility on nutrient agar slopes and for viability by inoculating them in the presence of *Aerobacter* sp. on non-nutrient agar. The sterilized cysts, thus treated, excysted readily in the presence of living bacteria, although on non-nutrient agar alone there was scarcely any excystment. These cysts have been used in all the subsequent experiments.

Aerobacter sp. five days old grown in nutrient broth at 37° C. was washed twice on the centrifuge with ice-cold saline, in which it was finally dispersed as a uniform suspension. Aliquots of the suspension, heated at 100° C. in a vigorously boiling water-bath for different periods, were tested for their capacity to induce the excystment of sterilized cysts. The bacteria were spread on non-nutrient agar plates and inoculated with large numbers of cysts. In the presence of even the 5-min. heat-treated bacteria, on rare occasions, only a few active amœbæ could be seen after 24–48 hr. incubation at 25° C., but they did not multiply. After three days, when washed resting cells of *Aerobacter* sp., preserved at 5° C. for 72 hr., were added, the great majority of the cysts excysted within 24 hr., showing that the excystment factor produced by *Aerobacter* sp. is highly thermolabile.

When placed on non-nutrient agar with *p*H adjusted at different levels (2·2, 3·0, 4·0, 5·0, 6·0, 7·0 and 8·0), the cysts did not show any sign of excystment, even after a period of 48–72 hr.; but when *Aerobacter* sp. was provided, excystment occurred generally and was independent of *p*H. Excystment, however, occurred more readily in the *p*H range 5–8.

Addition of reducing substances like cystine, cysteine, glutathione, thioglycollic acid and ascorbic acid to the non-nutrient agar did not induce excystment unless *Aerobacter* sp. was added.

Collodion cups (25 mm. diameter and 12 mm. height) were cast from a 6 per cent solution of collodion in ether–ethanol mixture (Merck) and sterilized in distilled water by autoclaving for 15 min. at 15 lb./sq. in. A layer of non-nutrient agar was poured in the sterile cups, which were placed on the surface of a papain-digest meat-agar plate heavily seeded with *Aerobacter* sp. Plenty of cysts were inoculated on the non-nutrient agar surface in the cups and incubated at 25° C. In the control experiments, the nutrient agar was not seeded. The majority of cysts excysted within 24 hr. in experiments in which *Aerobacter* sp. was inoculated in nutrient agar and allowed to multiply actively. After 48–72 hr. the amœbæ either encysted or died due to the lack of food. In control experiments only a few active amœbæ could be seen. This experiment clearly shows that *Aerobacter* sp. produces some substance that passes through a collodion membrane and into non-nutrient agar and causes the excystment of the amœbal cysts.

The experiment was repeated by reversing the relative positions of the seeded nutrient and non-nutrient agars—the seeded nutrient agar being placed in the collodion cup and the cysts on the surface of non-nutrient agar. In yet another series of experiments, the seeded nutrient agar in the cup was replaced by nutrient broth inoculated with *Aerobacter* sp. It was found that the factor was elaborated by *Aerobacter* sp., growing in the nutrient agar or broth as the case may be, and diffused through the collodion membrane into the non-nutrient agar, where its presence was revealed by the ready excystment of the amœbal cysts when placed on it. The factor could not be found in the unseeded controls.

It would appear that an excystment factor is produced by the actively proliferating culture of *Aerobacter* sp., which is capable of diffusing easily and rapidly through a collodion membrane into the agar gel. The factor is thermolabile and does not appear to be related to either *p*H or to any of the reducing substances tried by us, although both these factors may be expected either to condition the cysts to the action of the excystment factor or augment its potency. Work on the isolation and further characterization of the factor is now in progress.

Utilization of Xanthin by Mould Fungi

The utilization of purines by fungi as the sole source of nitrogen in their nutritive media has been reported in the literature only in a few cases[1–3]. No work concerning the utilization of xanthin by mould fungi appears to have been published.

One of us (E. D. M. T.) has already shown[4] that many fungal species representing all the fungal groups were able to grow luxuriantly in a medium containing uric acid as the only source of nitrogen. It was also possible to demonstrate the presence of the uricase enzyme in those fungi.

The experiments reported here carried out on xanthin have revealed, as Table 1 shows, that many mould fungi representing the different systematic groups are able to utilize xanthin as the only source of nitrogen.

The basic medium utilized was Czapek–Dox. The sodium nitrate of this medium was replaced by nitrogen-equivalent amounts of xanthin. The salts used in preparation of the medium were *A.R.* grade. The cultures were made in 50-c.c. Erlenmeyer flasks each containing 15 c.c. of the sterilized medium; five flasks were made for each individual fungus. All the flasks were inoculated with the same standard inoculum; the inoculated flasks were incubated at 28° C. for eight days, after which the dry weight of the mycelial mats was recorded.

Preliminary enzymatic studies have revealed the presence of xanthin-dehydrogenase enzyme in some of the fungi examined.

Inhibition of L-Asparaginase in Extracts of *Mycobacterium phlei* by D-Asparagine

THE concept that substances related chemically to a metabolite might interfere with the normal function of that metabolite or displace it from the site of attachment to the appropriate enzyme[1] is now well established. Accordingly, an unnatural stereoisomer of a metabolite could also be regarded as a potential antimetabolite; but it was surprising to find that only a few unnatural amino-acids did, in fact, interfere with the growth-promoting effects of their natural antipodes. Thus, D-leucine[2] and D-tryptophan[3] interfere with the growth-promoting effects of the corresponding L-isomers in lactobacilli, and D-glutamic acid was found partially to inhibit the activity of the L-glutamic acid decarboxylase obtained from *E. coli*[4].

In the course of studies on the asparaginase activity in cell-free extracts of *Mycobacterium phlei*, we found that L-asparagine, but not the D-isomer, was attacked by this enzyme. Moreover, D-asparagine was found to inhibit the enzymatic deamidation of the L-isomer.

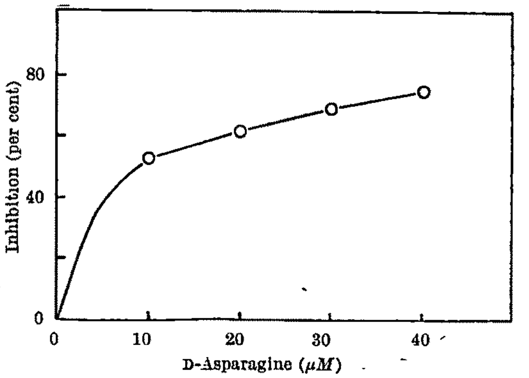

Fig 1 Inhibition of L-asparaginase activity by increasing concentrations of D-asparagine. Total volume: 1 ml., containing L-asparagine, 10 *μM*; D-asparagine, varying from 0 to 40 *μM* (Nutritional Biochemical Corp., U.S.A.). Bacterial extract, 2·5 mgm. protein; phosphate buffer *p*H 8·2, *M*/150. Incubation, 90 min. at 37° C.

The organism (*M. phlei* 271 from the culture collection of this Department) was grown in Roux bottles on nutrient agar supplemented with 0·1 per cent 'Tween-80' (polyoxyethylene sorbitan mono-oleate, Atlas Powder Co., U.S.A.). After incubation at 35° C., for three to four days, the bacteria were washed three times with distilled water, centrifuged and concentrated to about 2–3 gm./20 ml. of wet weight.

The thick suspension was disintegrated by a Raytheon 9*KC* sonic vibrator for 25 min. The supernatant, from which the debris was removed by high-speed centrifugation (at about 20,000 *g* for 20 min.), was dialysed against running water for 13–15 hr. The whole procedure was carried out in the cold room. The protein content of the dialysate was determined by Mehl's biuret method[5]. The asparaginase activity of the extract was estimated from the ammonia formed (by the Conway microdiffusion method) and from the amount of aspartic acid produced (by quantitative paper chromatography, after Giri *et al.*[6]).

Fig. 1 shows the effect of increasing amounts of D-asparagine on the inhibition of the L-asparaginase activity; at an inhibitor/substrate ratio of 4 : 1, an inhibition of 75 per cent was obtained. In order to establish the nature of the inhibition the reaction

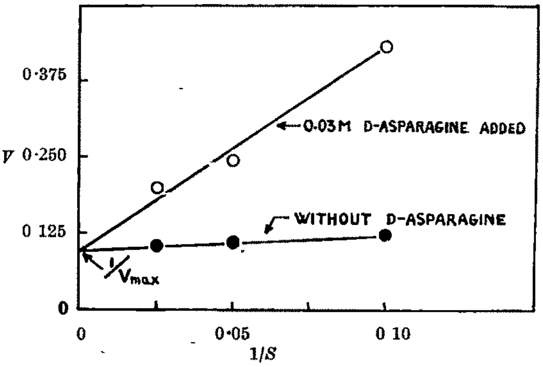

Fig. 2. Effect of substrate concentration on inhibition of asparaginase activity by D-asparagine. The same arrangement as in Fig. 1, except for concentrations of substrate and inhibitor. L-asparagine concentrations were 10, 20 and 40 *μM* respectively; D-asparagine, 0 and 30 *μM* respectively. *V*, reaction velocity, *μ*mole of ammonia produced in 90 min. *S*, substrate concentration in *μM*

velocity was measured at various concentrations of the substrate (L-asparagine) in the presence and in the absence of the inhibitor (D-asparagine). The results presented in Fig. 2 (after Lineweaver and Burk[7]) show that D-asparagine inhibits competitively the L-asparaginase activity of *M. phlei.*

Effect of Sialoadenectomy on Thyroid Activity

THE rapid appearance of iodide in saliva following administration of iodide iodine-131 has been demonstrated[1], and its measurement has proved useful in the evaluation of the thyroid status of clinical cases[2]. Recently, an experiment has been reported[3] which suggested that the salivary glands may play an important part in thyroid metabolism, involving the removal of iodine-131 diiodotyrosine from the peripheral circulation. Dehalogenation processes by characteristic enzymes in the salivary gland tissue have been observed[4].

Our present preliminary observations indicate that the salivary glands play an important part in regulating the activity of the thyroids of the mouse and the rat. We employed adult male mice (N.I.H.) weighing 25 ± 1 gm. throughout. Animals were housed in conventional cages in a room the temperature of which was maintained at 25 ± 3° C. The daily ration consisted of commercial mixed grains and water, *ad libitum.* Submaxillary, parotid and sublingual glands were removed under aseptic conditions seven to ten days prior to measurements of thyroid activity. Sham-operated controls were employed throughout. In each experiment sham controls and sialoadenectomized animals were given equal periods of post-surgical rest. Carrier-free iodine-131 as iodide and carrier-free phosphorus-32 as phosphate were administered intraperitoneally in the doses indicated in the tables. Experimental groups contained at least ten and not more than twelve animals. Thyroids were removed, weighed on a microbalance to the nearest 0·01 mgm., and plated for radiological assay as described previously[5]. Radio assays of iodine-131 were performed with the aid of an end-window Geiger–Muller counter and scaler; phosphorus-32 was assayed with the aid of a scintillation counter sensitive to β-particles and a Dumont photomultiplier tube. Assays were pre-set for count to give a statistical error less than 1 per cent. Results are expressed as counts per min./mgm. tissue or as a percentage of control-animal values.

The results in Table 1 shows that sialoadenectomy, performed on mice, increased the uptake of iodine-131 by the thyroid in the first four hours following administration of radioactive iodide. The iodine-131 content of the mouse thyroids, measured 24 hr. later, indicates a delayed turnover of iodine-131 in the sialoadenectomized animals as compared to that in the control groups. Repeated experiments substantiate the initial observations. Sialoadenectomy also produced similar changes in the rate of iodine-131 metabolism in the thyroids of rats. 24-hr. thyroid iodine-131 levels are always less than those found in sham-operated control rats (Table 2).

Table 1. EFFECT OF SIALOADENECTOMY ON UPTAKE OF IODINE-131 BY MOUSE THYROID FOLLOWING INJECTION OF 5 μC. IODINE-131 PER 25 GM. BODY-WEIGHT

Group	Average 4-hr. uptake (counts per min./mgm.)	(Per cent)	Average 24-hr. uptake (counts per min./mgm.)	(Per cent)
Sham controls	1,350 ± 147*	100	4,958 ± 133*	100
Sialoadenectomized	1,736 ± 234	129	1,932 ± 373	39

* Standard error of the mean.

Table 2. EFFECT OF SIALOADENECTOMY ON THYROID ACTIVITY OF RATS 24-hr. uptake, 20 μc. iodine-131 per 100 gm. body-weight

Group	Average counts per min./mgm.	Per cent
Controls	824 ± 33*	100
Experimental	555 ± 54	67·3

* Standard error of the mean.

To test the probable changes of the levels of thyroid-stimulating hormone in animals deprived of their salivary glands, resort was made of the titre of the hormone indicated by phosphorus-32 uptake by the thyroid glands[6]. The results indicated in Table 3 are the preliminary observations following uptake of phosphorus-32 for 1 hr. by mouse thyroids in control and sialoadenectomized animals. Administration (intraperitoneal) of 5 μgm. of the hormone restored the phosphorus-32 activity of the thyroids of desalivated mice to normal levels (Table 3).

Table 3. TITRE OF THYROID-STIMULATING HORMONE AND EFFECT OF INJECTED HORMONE MEASURED BY PHOSPHORUS-32. UPTAKE OF PHOSPHORUS-32 BY MOUSE THYROIDS 1 HR AFTER INJECTION OF 50 μC RADIOACTIVE PHOSPHATE

Group	Average counts per min./mgm.	Per cent
Controls	366 ± 25	100
Sialoadenectomized	227 ± 29	62
Controls + 5 μgm hormone 1 hr prior to phosphorus-32	433 ± 63	118
Sialoadenectomized + 5 μgm. hormone 1 hr. prior to phosphorus-32	416 ± 160	114

The observations recorded here indicate that the salivary glands play an important part in the regulation of the activity of the thyroid gland, probably via control of the production and/or the utilization of thyroid-stimulating hormone. The influence on the titre of the hormone is apparent since the desalivated mice in these studies showed uptakes of phosphorus-32 by the thyroid that were consistently lower (30–38 per cent) than that observed in intact control animals. Further, the phosphorus-32 uptake-response of sialoadenectomized mice to a single 5-μgm. dose of thyroid-stimulating hormone showed a gain of 84 per cent above their base values, whereas control animals exhibited a gain of only 18 per cent above their base values.

The thyroids of sialoadenectomized mice incorporate iodine-131 more rapidly than those of control animals in the 4-hr. test period, but they also appear to utilize thyroid iodine-131 at a subnormal rate as indicated by the iodine-131 content of the thyroids after 24 hr. The initially higher uptake of radioactive iodine in the sialoadenectomized mice may be due to the loss of the normal iodide spillway into the saliva[1] which could lead to higher concentrations in the circulating fluids with consequent increase in iodine-131 trapped by the thyroid. The reduced levels of thyroid iodine-131 and the low titre of thyroid-stimulating hormone indicated by uptake of phosphorus-32 are not difficult to explain in view of our preliminary studies on the rate of disappearance of thyroid iodine-131. The uptake of iodine-131 in sialoadenectomized mice is maximal at 6–8 hr. and the iodine-131 disappears from the thyroid quite slowly or not at all in the 24–48 hr. interval, indicating reduced titre of thyroid-stimulating hormone.

The increased sensitivity of thyroid-stimulating hormone (Table 3) suggests that some regulating mechanism is impaired when salivary glands are removed from the mouse. Whether the effects produced are due to a hormonal or enzymatic regulator presumably present in salivary glands is not yet known.

We acknowledge the technical assistance and co-operation of Florence Fries. The thyroid-stimulating hormone was kindly given by Dr. S. Steelman of the Armour Laboratories. This study was sponsored by a grant from the National Cancer Institute.

Effect of Vitamin D on the Phosphôrus Content of Rachitic Rat Cartilage

EARLIER investigations[1] in these Laboratories had indicated that vitamin D influenced carbohydrate metabolism in calcifying cartilage of the albino rat. Since carbohydrate and phosphorus metabolism are closely interlinked, the present investigation was undertaken with the view of determining the influence of vitamin D on the phosphorus content of rachitic rat cartilage.

Healthy albino rats four weeks old were distributed in seven groups; the first six groups contained ten rats in each, while the last one contained twenty animals. All the animals were fed a modified rachitogenic diet[2] for twenty-one days. At the end of this period, animals in group I were killed, their tibial epiphyseal cartilages quickly removed and placed individually in tubes and dried at 90° C. Animals in groups II–VII were fed a single dose of vitamin D (4,000 I.U.). Exactly 24 hr. after vitamin D administration, rats in group II were killed and their tibial cartilages removed and dried. The animals in the remaining groups were killed at intervals of 24 hr. The dried cartilage of each rat was weighed and its total phosphorus content determined colorimetrically after wet ashing. The results are presented in Table 1.

It will be seen that the administration of vitamin D caused a gradual increase in the total phosphorus content of the cartilage. At 96 hr. after vitamin D administration, the phosphorus content of the cartilage was maximum, being about twice that contained in the cartilage of the untreated rachitic animal.

It is not clear at this stage why the phosphorus content of cartilage decreases after 96 hr. It may be mentioned, however, that this fall coincides with (*a*) the maximum increase in calcifying capacity *in vitro* shown by the cartilage of the animals treated with vitamin D, and (*b*) the commencement of calcification *in vivo*, both of which have been demonstrated by Dikshit and Patwardhan[3] to occur at 96 hr. after administration of vitamin D.

Table 1. TOTAL PHOSPHORUS IN CARTILAGE FROM RACHITIC RATS AND RATS GIVEN VITAMIN D

Group No.	Hr after vitamin D	No. of observations	μgm. phosphorus/ mgm. dry cartilage
I	0	10	9 78 ± 1·72
II	24	10	11 00 ± 1 15
III	48	10	14 13 ± 1 71
IV	72	10	13 14 ± 1·49
V	96	10	20·94 ± 2·37
VI	120	10	17·21 ± 2·38
VII	144	20	12 21 ± 1 41

The results reported here indicate that the phosphorus content of rachitic cartilage increases due to the influence of vitamin D preparatory to the onset of calcification. Further work is in progress to determine the effect of vitamin D on the various phosphorus compounds in the healing cartilage.

Dominant Lethality induced by X-Rays in Haploid and Diploid *Saccharomyces cerevisiae*

IN a previous paper[1], evidence was presented for the presence of dominant lethals in X-irradiated haploid yeast cells. Diploid yeast zygotes formed by the conjugation of one irradiated and one unirradiated haploid cell were found to exhibit signs of radiation damage, including swelling, delay in division and death. The damage responsible for inactivation of these half-irradiated zygotes was defined operationally as dominant lethal damage. The present communication describes a continuation of these experiments in which diploid cells homozygous for mating type were employed along with the two haploid cultures previously used. These diploid cells will conjugate with haploid or diploid cells of opposite mating type when placed in direct contact, thus permitting a similar determination of the frequency of dominant lethals in diploid cells. This was of interest because previous studies of the survival of X-irradiated yeast cells of higher ploidy[2] suggested that the frequency of this type of damage might increase with increasing ploidy.

The diploid cells arose spontaneously in the haploid cultures and were isolated with a micromanipulator. The amounts of deoxyribonucleic acid, ribonucleic acid and dry weight per cell for the haploid and diploid cultures were all approximately in the ratio 1 : 2, confirming the expected ploidy of these cultures[3]. The cells used in the experiments were harvested from 24-hr. streak cultures on yeast extract – dextrose agar plates (½ per cent yeast extract, 1 per cent dextrose), suspended in buffer and maintained at 4° C. until used. Viability was nearly 100 per cent. Single, non-budding cells were isolated with a micromanipulator and paired with similar cells of the opposite mating type as described previously[1]. The medium used for conjugation and growth of the cells after irradiation was yeast extract – dextrose agar (see above) and incubation was at 30° C. Conjugation usually occurred within four to five hours. The frequency of conjugations averaged about 90 per cent and was relatively uninfluenced by irradiation of the parent cells. For each of the following crosses: haploid × haploid (oo), haploid × diploid (oO), diploid × haploid (Oo) and diploid × diploid (OO), one, or the other, or both of the parental cells was irradiated with X-rays (the symbol on the left represents a cell of the α-mating type, that on the right the a-mating type; o represents a haploid cell, O a diploid cell. A filled-in circle is used to indicate that the cell was irradiated before pairing). Zygote viability was determined from about 80–100 pairs of cells at a number of dose points (3–7) for each of the twelve possible combinations. The viability of the haploid and diploid cells for vegetative division was determined in a similar manner by the isolation of about a hundred single, non-budding cells for each dose-point studied. The criterion of viability was the ability of the zygote or cell to develop into a colony containing more than forty cells.

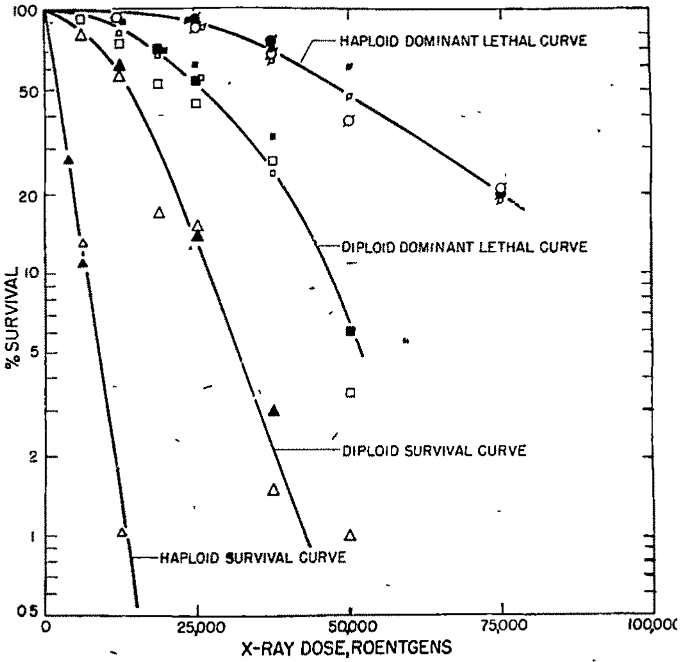

Fig. 1. Haploid dominant lethal curve: ϕ, •o; ɸ, o•; ϕ. •O; ɸ, O•. Diploid dominant lethal curve: □, ●○; ■, ○●; □, ●o; ■, o●. Diploid survival curve: △, ● – $\alpha\alpha$ diploid; ▲, ● – aa diploid. Haploid survival curve: △, • – α haploid; ▲, • – a haploid

In agreement with a number of previous studies, the diploid cells of both mating types were found to be less sensitive to X-ray inactivation than the haploid cells. However, the frequency of dominant lethals induced in the diploid cells was considerably greater than in the haploid cells. The results of these experiments are summarized in Fig. 1. Within the accuracy of the experiments, the yield of dominant lethals for either haploid or diploid cells was the same for irradiation of either mating type and in addition was independent of the ploidy of the unirradiated parental cell; that is, •o ≡ o• ≡ •◯ ≡ ◯• and ●◯ ≡ ◯● ≡ ●o ≡ o●. Furthermore, there is an approximate dose reduction factor of 2 between the haploid and diploid dominant lethal curves, suggesting that the amount of dominant lethal damage depends on the product of ploidy and dose.

Examination of the results from all crosses where one or both of the parental cells had been irradiated revealed that for a given value of the parameter $p_1D_1 + p_2D_2$ (where p_1 and p_2 are the ploidies of the parental cells and D_1 and D_2 are the respective doses received), the viability of all zygotes except haploid × haploid (••) was approximately the same. A typical example of this relation is presented in Table 1. Agreement of the results in terms of this parameter would be consistent with the assumption that dominant lethal damage was most important in inactivation of triploid and tetraploid zygotes which had been formed by two irradiated cells. That the haploid × haploid cross (••) did not fit was considered to be due to the expression of some recessive lethal damage.

Table 1

Cross	p_1	p_2	D_1 (krep)	D_2 (krep)	$p_1D_1+p_2D_2$	Fraction of viable zygotes
●•	2	1	16·7	16 7	50 0	0 49 ± 0·05
●•	2	1	12 5	25 0	50 0	0·54 ± 0 05
●●	2	2	12 5	12·5	50 0	0 52 ± 0 05
●●	2	2	18 75	6 25	50·0	0·46 ± 0 05
●○	2	2	25 0	0	50 0	0·44 ± 0 07
• ○	1	2	50 0	0	50·0	0·47 ± 0·06
• •	1	1	25·0	25·0	50 0	0·17 ± 0 04

The dependence of dominant lethals on the product of ploidy and dose would be consistent with this damage arising from inviable recombinations of broken chromosome ends—the frequency of breaks would most probably increase with both these variables. However, many critical cellular components of yeast cells are known to increase in integral fashion with ploidy[3], and similar reasoning might be applied to identify the damage with these components. The present experiments do not permit a definite characterization of the dominant lethal damage; they do, however, show that the frequency of this damage increases with the ploidy of the irradiated cell.

A more complete account of this work, including experimental details as well as additional studies with vegetative cells of different ploidies, will appear in a later publication.

Amino-acid Composition of Hæmoglobin E

In 1955, some of us published the results of the determination of the amino-acid composition of hæmoglobins A, B (also known as S), C and F [1-3]. In that work we used a modification of the column hromatographic method of Stein and Moore. We were recently able to study a family of which some members are carriers of hæmoglobin E. We took advantage of this opportunity to determine the amino-acid composition of this hæmoglobin by the use of the method mentioned in the previous publication[1].

The family came from Indonesia; the father (1) is of mixed British–Javanese extraction (see Fig. 1). He was somewhat anæmic (hæmoglobin 12 gm./100 m. blood). His hæmoglobin was found to contain 1 per cent of fœtal hæmoglobin, which could be emonstrated by three methods available to us alkaline denaturation, electrophoresis and chromatoraphy[4]). The presence of about 11 per cent of hæmoglobin F, together with the hæmatological findings, places this otherwise healthy man in the roup of the Cooley trait (thalassæmia minor).

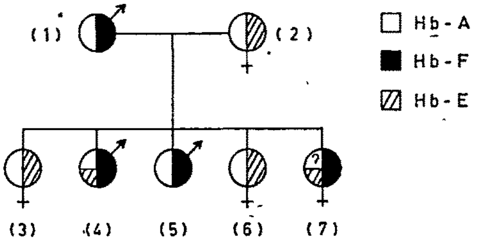

Fig. 1. Pedigree of the family studied

The mother (2) is of mixed Indonesian–Chinese xtraction (from which part of China her mother ame is unknown); her Indonesian father's family ame from Northern Celebes. In the blood of this healthy woman an abnormal hæmoglobin was detected and shown by paper electrophoresis to be hæmoglobin E [5-7]. The percentage of this hæmoglobin E was 38 per cent. Of the five children of this marriage, numbers 3 and 6 had hæmoglobin A and E in their blood, the percentage of hæmoglobin E being respectively 27 and 44 per cent. The blood of one child (5) showed a small percentage of fœtal æmoglobin (6 per cent), as did the father's blood. Another child (4), a boy of five years, the only member of the family with a severe anæmia, showed he clinical picture of a moderately severe Cooley's anæmia. His blood contained nearly 41 per cent of œtal hæmoglobin, 38 per cent of hæmoglobin E and 21 per cent of normal hæmoglobin. The youngest hild (7) is now seven months of age. Her blood still ontains 71 per cent of fœtal hæmoglobin. In a normal child of that age only traces of fœtal hæmoglobin can be detected. Besides this fœtal hæmoglobin, hæmoglobins E and perhaps A could be detected. Similar families with thalassæmia minor and hæmoglobin E trait in their ancestry and with members whose hæmoglobin was a mixture of hæmoglobins E and F have been described previously[5,7].

As we were unable to separate quantitatively hæmoglobins A and E, we had to use mixtures of both hæmoglobins for our amino-acid determinations. We used the hæmoglobin of cases 2, 3 and 6 containing, respectively, 38, 27 and 44 per cent hæmoglobin E.

Table 1. Amino-acid Composition of 48-hr. Hydrolysates of Different Hæmoglobin Samples
(The values are given as gm. per 100 gm. protein)

Amino-acid	Hæmoglobin A	Patient 2 (38 per cent hæmoglobin E)	Fraction patient 4 (65 per cent hæmoglobin E)
Aspartic	10·5	10·3	10·35
Threonine	5·5	5·45	5·7
Serine	4·45	4·75	4·45
Glutamic	7·25	7·8	7·0
Proline	4·95	4·65	4·9
Glycine	4·55	4·75	4·45
Alanine	9·95	10·3	9·95
Cystine	1·0	1·05	1·15
Valine	10·9	10·8	11·0
*iso*Leucine	0·35	0·4	0·35
Leucine	15·15	14·9	14·3
Tyrosine	3·85	4·15	3·75
Phenylalanine	7·85	7·6	7·85
Lysine	9·9	9·8	9·95
Histidine	8·3	8·25	8·25
Arginine	3·35	3·65	3·25

The hæmoglobin of patient 4 was then re-tested after the hæmoglobin F had been removed by means of column chromatography. After this procedure, the hæmoglobin E content was 65 per cent, the remainder being hæmoglobin A. The analysis was done as previously described[1]. In Table 1 the results for cases 2 and 4 are given. Those of cases 3 and 6 are in agreement with the two mentioned here.

These results make it likely that the amino-acid composition of hæmoglobin E is the same as that of normal hæmoglobin. The same is the case for hæmoglobin B. The N-terminal residues of hæmoglobin E are the same as those of the hæmoglobins A, C and B, namely, five valine groups[8]. These findings make it probable that man can synthesize different hæmoglobins which have the same amino-acid composition and the same N-terminal residues, but differ in some physical properties. The occurrence of each of these hæmoglobins is dependent on the existence of one abnormal gene.

Protein synthesis seems to occur under the direct influence of one or more genes. Therefore it is possible that these relatively small differences in structure between hæmoglobins A, E and B which are caused by the presence of one abnormal gene can provide us with some information about the mode of action of these genes in the synthesis of hæmoglobin. Two different possibilities arise: first, the indistinguishable amino-acid composition and the identical N-terminal residues point to an identical sequence of the amino-acids in the polypeptide chains in these different hæmoglobins. If this is true, the differences between these hæmoglobins must be the result of differences in folding of the polypeptide chains and of differences in bonds between these chains. In this case one might conceive that one group of genes is responsible for the synthesis of the polypeptide chains and that a separate gene or a small group of genes regulates the folding of those chains and the bonds between them. This would make protein synthesis in at least two phases likely.

A second possibility is that there are in fact differences in the amino-acid sequences in the polypeptide chains and that these differences are the cause of the differences between hæmoglobins A, E and B. Consequently a different folding of the polypeptide chains must be assumed in the different hæmoglobins. Hæmoglobin C differs from hæmoglobins A, E and B in lysine content. This points to the possibility that the gene responsible for the formation of hæmoglobin C influences the synthesis of the polypeptide chains. In view of the great differences in amino-acid composition between hæmoglobins A and F, one must assume that the synthesis of these two proteins is regulated by quite different groups of genes.

This investigation has been supported by a grant of the Netherlands Organisation for Pure Research (Z.W.O.).

Staining of Wool by Bacterial Pigments

Staining of the fleece by bacterial pigments has been described[1], and a number of colours have been attributed to a variety of organisms. Recent investigations on the staining of Corriedale fleeces during periods of wet weather have shown that several stains similar to some of those described in previous work can be caused by the oxidation or reduction products of the pigment pyocyanine, produced by a single species *Pseudomonas aeruginosa* (Schroeter) Migula.

Growth and pigment production by the organism are dependent upon the rate of drying of the fleece from saturation[2]. At saturation, the *p*H of basal fleece of the susceptible type is 5·6–6·0, and this *p*H has been found to be the optimal for rapid production of pyocyanine in culture. Under such conditions of wetness and *p*H the fibres are stained green. However, after prolonged wetting, colour banding occurs in the fleece, and brown and red bands appear in succession above a green band. Upon drying, banding disappears and a yellowish-brown or green colour results.

P. aeruginosa was isolated as a nearly pure culture from wool showing green staining; and after purification it was grown in a synthetic culture medium containing phosphate, sulphate, magnesium and ferric ions with glycerol and urea. Growth for twelve days at 22° C. gave maximum production of pyocyanine, at which stage the cultures were passed through a Seitz filter. Extraction of the filtrate with chloroform yielded a coloured solution which was later separat into pyocyanine (blue), hemipyocyanine (yellow) a pyorubrin (red) by elution through an alumi column. The aqueous layer also retained pigmen and these fluoresced in ultra-violet light. Separati of pyocyanine is also achieved by converting it its red salt when the chloroform extract is shak with 1 per cent hydrochloric acid. The salt is tak up into the aqueous layer, and hemipyocyanine a pyorubrin remain in the chloroform layer.

Reduction of aqueous pyocyanine solution ov the entire *p*H range results in the breakdown pyocyanine in different ways according to the init *p*H of the solution. At *p*H 5·6 and above, breakdo of the blue solution is direct to the leuco-base. B tween *p*H 5·6 and 4·8, when the colour of the soluti is violet, the breakdown is by two steps, to green a then to the leuco-base. Below *p*H 4·8 when the sol tion is red, reduction is by three steps, yellow to gre and finally to the leuco-base. Pigment solutions *p*H 4·8–5·6 are easily reduced to green, whereas *p*H's below 3·5 the stepwise reduction is more di cult. These results are in accord with those Friedheim and Michaelis[3] except that these auth make no reference to the yellow reduction produ which has been found to be the first step in t reduction of pyocyanine in the lower *p*H ranges.

Of all the pigments isolated, only hemipyocyani and pyocyanine have been found to stain wool fibr The colour produced in the fibres was dependent up the *p*H of the stain solution. Table 1 shows t results of such tests.

When pigment is absorbed into the fibre from alkaline dye solution, the change in colour from bl to the leuco-base shows that reduction of the py cyanine molecule has occurred. However, oxidat to the blue colour occurs upon washing. Staini between *p*H 5·8 and 5 results in a decrease of bl and an increase of green in the fibre. The gre coloration is, however, formed in the fibres in soluti and subsequent oxidation does not change it. Th it appears that over this particular small range *p*H values reduction of the oxidized pyocyan molecule has occurred, causing the green reducti product to be formed. The dyestuff produced rema within the fibre on washing in warm distilled wa and in 1 per cent hydrochloric acid, but the lat converts the green coloration to a red colour simi to that produced in fibres dyed in solutions bel *p*H 3·0 : this change is reversible. Thus it appe possible that the red band at distal staple leve formed after prolonged wetting of the fleece, is caus by acidic degradation products of the tip[4]. Neit the green- nor the red-dyed wool can be changed blue.

It appears that the pyocyanine molecule is retain within the fibre but not due to bonding, wher

Table 1. Clean Scoured Wool stained with Pure Pyocyanine in 0·1 *M* Phthalate Buffer at 37° C. for 48 hr.

*p*H of dye solution	Colour of dye solution	Colour of stained wool		Wool washed in distilled water (80° C.)	Wool washed in 1 per cent hydrochloric acid (warm)
		In dye solution	After washing in distilled water (20° C.)		
8·4 and above	Blue	Colourless	Blue	All absorbed pyocanine removed from fibres	All pigment removed as red ac salt
7·4	Blue	Colourless	Blue	,,	,,
5·8	Blue	Green	Blue-green	Pyocyanine partly removed but green remains in fibres	Pyocyanine removed as acid sal green pigment turns red an remains in fibre
5·0	Violet	Green	Green	No pigment removed into solution	No acid salt removed but gree pigment turns red
3·0	Red	Yellowish-brown	Yellowish-brown	,,	,,
2·0	Red	Red	Red	,,	,,

e green and red pigments, as shown by the stability nd loss of indicator reaction at alkaline *p*H values, ppear to be bonded to the fibre. It is likely that e combination of an amino-group and the dye olecule will result in the formation of an aminohenazine compound having dyestuff properties.

We wish to thank Prof. J. A. R. Miles, of the edical School, Otago University, for confirming our entification of the bacterium.

Protein Denaturation in Heavy Water

The increasing availability of deuterium oxide esulting from developments in nuclear energy renders t opportune to reopen the general question of the ffects of deuteration on biological activity. Numerous nvestigations have utilized deuterium as a tracer. here are few quantitative studies, however, which elp provide a basis for an understanding of the rofound consequences of extensive deuteration on iving organisms. To this end, we have now carried ut experiments on the denaturation of ovalbumin n 99·6 per cent heavy water.

The denaturation of ovalbumin by highly conentrated urea solutions has been described in detail y Simpson and Kauzmann[1] and affords a reasonably ontrolled system adapted to comparative kinetic tudies in heavy water and water. Following closely he experimental procedures and methods of analysing he data described by Simpson and Kauzmann, we ave made polarimetric measurements of the deaturation of ovalbumin in heavy-water solutions which are 7–8 molar in deuterourea. Under these onditions a markedly slower rate of denaturation s observed in heavy water as compared to water.

The polarimetric measurements were performed in 99·6 per cent heavy water in water-jacketed polarimeter tubes 2 dm. long; the temperature was maintained at 30·0° C. ± 0·2° C. A Rudolf high-precision model 80 polarimeter equipped with a monochromator supplying light of wave-length 5893 A. was employed. Reagent grade urea was exchanged with 99·6 per cent heavy water four times yielding a product urea-d_4, which gave by Kjeldahl determination N, 43·5 per cent (calculated for ND_2COND_2, N, 43·7 per cent). Stock solutions of ovalbumin in heavy water were prepared by dissolving four-times crystallized ovalbumin (obtained from Pentex Inc., Kankakee, Illinois) in 99·6 per cent heavy water and centrifuging the solution for two hours at 31,000 *g*. Morowitz and Chapman[2] have shown that all exchangeable hydrogens in a globular protein are replaced by deuterium atoms within 20 min. from the time of dissolution in heavy water. Protein concentration was determined in the solutions by dry weight and spectrophotometrically, using for ovalbumin E (1%, 1 cm.) = 7·5 at 279 mμ. In order to provide a valid basis for the comparison of our heavy-water measurements with observations in ordinary water, it is essential that the same preparation of crystallized ovalbumin be used for the kinetic measurements in both solvents.

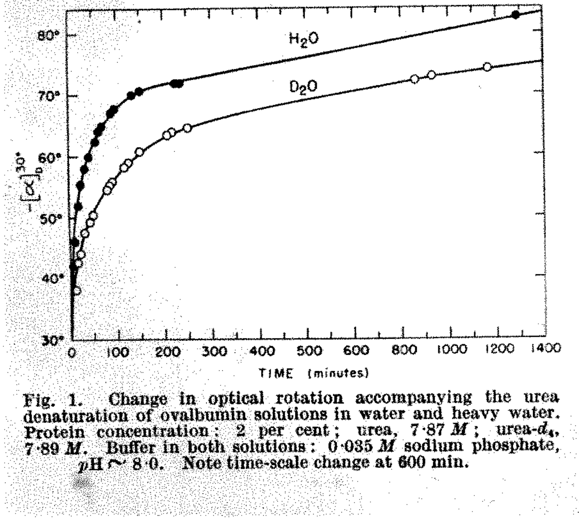

Fig. 1. Change in optical rotation accompanying the urea denaturation of ovalbumin solutions in water and heavy water. Protein concentration: 2 per cent; urea, 7·87 *M*; urea-d_4, 7·89 *M*. Buffer in both solutions: 0·035 *M* sodium phosphate, *p*H ~ 8·0. Note time-scale change at 600 min.

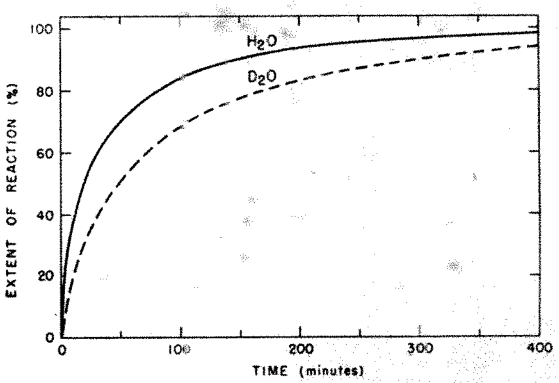

Fig. 2. Comparison of rates of denaturation in water and heavy water. Extent of reaction (initial fast reaction) is calculated at each point by the relationship:

$$\% \text{ reaction completed} = \frac{[\alpha] \text{ observed} - [\alpha] \text{ initial}}{[\alpha] \text{ final} - [\alpha] \text{ initial}}$$

In Fig. 1 are presented the specific rotations $[\alpha]_D^{30°\text{C.}}$ for both water and heavy-water solutions. Neither the kinetic data obtained by Simpson and Kauzmann in water nor the data given here for heavy water are capable of representation by a simple first- or second-order graph. The analytical procedure developed by Simpson and Kauzmann has been applied to Fig. 1, yielding for the heavy-water data $-[\alpha_f] = 70°$, and for water, $-[\alpha_f] = 75°$. These final optical rotation values can be used to construct Fig. 2, from which the characteristic half-times of reaction can be determined: in heavy water, $t_{1/2} = 50$ min.; in water, $t_{1/2} = 18$ min. It thus appears that the rate of denaturation in heavy water is only about one-third that in ordinary water.

A surprising observation in the course of this work is the finding that the specific rotations $[\alpha]_D^{30°\text{C}}$ of ovalbumin in pure water and heavy water are practically identical. For ovalbumin in heavy water we find $-[\alpha]_D^{30°\text{C}} = 29·7 \pm 0·6°$, for water, $30·0 \pm 0·3°$ C.; Simpson and Kauzmann give 30·0° for the specific rotation of ovalbumin in water. The substitution of deuterium for hydrogen thus does not lead to equilibrium structural alterations by the criterion of optical rotation.

On the basis of the results described here it cannot be decided whether the marked slowing down in the rate of denaturation in the protein–urea–heavy water system is due to alterations in the interaction between the protein and the solvent, the protein and the urea, or the solvent and the urea. However, all these interactions involve hydrogen bonding, and it would appear plausible to attribute the change in rate to small differences in the strength of the hydrogen bonds when hydrogen is replaced by deuterium. Thus, if the replacement of hydrogen by deuterium in hydrogen bonds existing between the protein and solvent leads to slightly more stable bonds, because of zero-point energy considerations, then multiplying the slight stabilization per bond by many bonds may produce the observed slowing down. In any event, it would appear that further studies in deuterated systems may contribute to a clearer understanding of the role of hydrogen bonding in maintaining protein configuration.

This work was carried out under the auspices of the U.S. Atomic Energy Commission.

Assay of Possible Carcinogenic Hydrocarbons from Cigarette Smoke

Recently, Cooper and Lindsey[1] and Seelkopf[2] described the identification and assay of the carcinogen 3,4-benzpyrene and other polycyclic hydrocarbons in a neutral aromatic fraction of cigarette smoke. These investigators, in the attempt to reconstruct conditions complying with those present in normal human cigarette smoking, smoked cigarettes in an automatic fashion which effected strictly regular intermittent puffing.

The present communication describes a similar investigation of cigarette smoke under conditions of smoking and collection of smoke products which differed from those used by Cooper and Lindsey and by Seelkopf. The time taken to smoke a cigarette of average weight 1·1 gm. to a butt of approximately 1·4 cm. was varied between 7 and 12 min.; 2–4 sec. draws were made during the course of smoking. It was assumed that varying the tempo of smoking as indicated coincided more with reality than regular and 'average' smoking. The smoke products were collected in acetone chilled to − 70° C. 500 cigarettes, used in the present operation, yielded 15·0 gm. of smoke products.

A neutral aromatic fraction was prepared and fractionated by adsorption chromatography using alumina, silica gel and 'Florisil'. The chromatographic analysis was followed by inspection of columns and eluates under a filtered ultra-violet light, and eluates were screened by fluorescence spectrography. Ultra-violet absorption spectrophotometry was carried out for qualitative and quantitative determination of polycyclic hydrocarbons as an adjunct to fluorescence spectrography. In all determinations cyclohexane was used as solvent.

Table 1. Absorption Maxima (mμ)

3,4-Benzpyrene	403		385		37
Fluorescence spectrum IV	401	394	384	380	37
,, ,, VI	404·5	390	387		37

The range of polycyclic hydrocarbons present was found to be essentially the same as that demonstrated by Cooper and Lindsey[1b], pyrene being present in greatest concentration. In addition, other hydrocarbons were detected. Azulene, postulated by th London workers as likely to be present, was indicated in an initial eluate by its spectrum in the near ultra-violet and visible range. The presence of 1,2-benzanthracene, detected by fluorescence spectrography was substantiated by its ultra-violet absorption spectrum, giving an inflexion point at 384·5 mμ and peaks at 299, 288 and 276 mμ. It was present to the extent of 1 μgm. approximately. 3,4-Benzpyrene, th presence of which was established by both fluorescence spectrography and ultra-violet absorption spectrophotometry, was estimated at 7·4 μgm. by peak-heigh measurement against a standard 3,4-benzpyrene at 385 mμ. This concentration of 3,4-benzpyrene agrees with that estimated by Seelkopf. A rechromatography of the 3,4-benzpyrene fraction on activated alumina revealed the presence of two further components in low concentration, which had a blue-violet fluorescence in ultra-violet light and which were more strongly adsorbed than the 3,4-benzpyrene; thei fluorescence spectra are shown in Fig. 1. One spectrum IV, exhibits a slight hypsochromic shift with apparently increased fine structure, whereas the other, spectrum VI, shows a slight bathochromic shift relative to the 3,4-benzpyrene spectrum, such as may be brought about when a position of low free valence is substituted by an alkyl group (*vide* Schoental and Scott[3]). The absorption data in Table 1 demonstrate that the apparent shift of the shortest fluorescence band is paralleled by the shift in the longest absorption band, an approximate mirror-image relationship existing between the fluorescence and absorption spectra[3,4].

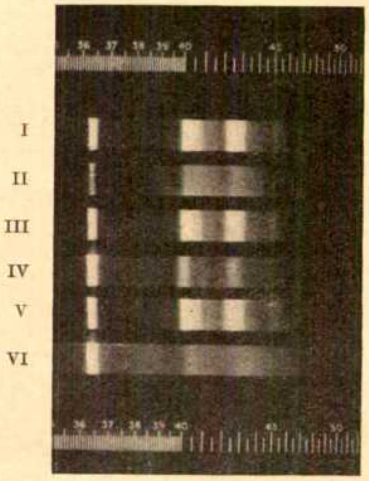

Fig. 1. Fluorescence spectra of three compounds isolated from cigarette smoke

No.	Spectrum	Exposure time (min.)
I	Standard 3,4-benzpyrene (0·1 mgm. per 100 ml.)	3
II	3,4-Benzpyrene derived from cigarette smoke	3
III	Standard 3,4-benzpyrene	3
IV	Unidentified *A*	8
V	Standard 3,4-benzpyrene	3
VI	Unidentified *B*	15

All samples are in cyclohexane

The quantitative estimation of the 3,4-benzpyrene nd 1,2-benzanthracene is regarded as having semiuantitative significance. The latter compound, hich satisfies the frontier electron density index for arcinogenicity of Nagata *et al.*[5], is shown by Steiner[6] o be of 'medium' carcinogenic potency. The conurrent action of the 1,2-benzanthracene, 3,4-benzyrene and the two compounds, the spectra of which esemble that of benzpyrene, on the animal body is ifficult to assess. A wide range of effects, from inibition through summation to synergism, is coneivable (*vide* Steiner[6]).

I am grateful to Dr. P. R. Peacock, director of esearch, and Mr. J. G. Chalmers, for helpful advice, nd to Mr. S. Breslin for printing and mounting of pectra. Further details, including temperatures ecorded during the smoking, will appear elsewhere.

Influence of a Magnetic Field on Thermal Convection Patterns

THERMAL instability during the chemical silvering f glass produces Bénard convection patterns in the eposited silver layer. An unstable condition prouced by cooling the silver solution to about 10° C., ouring it over the top surface of glass plates at 5° C. arranged horizontally, so as to produce a layer bout 3 mm. thick, gave silver patterns as shown in ig. 1. A very unusual and pronounced difference ccurred in the details of the shapes of the convection atterns when formed in the presence of a magnetic ield.

When the glass was cooled to the same temperture as the silvering solution and heated from elow at two points by the poles of an electro-agnet at room temperature, a different type of conection occurred in these locally heated areas. The onvection lines centred toward he heated regions, as shown in ig. 2 for two directions of the agnet current, the magnet posiion unchanged. The shape of the onvection lines disclosed an unsual effect, namely, a characteristic ifference between the patterns over he north and south poles. The adiating lines at the north pole isclose little curvature and stream oward a common focus at the entre, whereas at the south pole he lines have greater curvature and o not meet at a common centre.

When an alternating current 60 ~) was applied to the electroagnet, the convection patterns ppeared the same over both pole ieces.

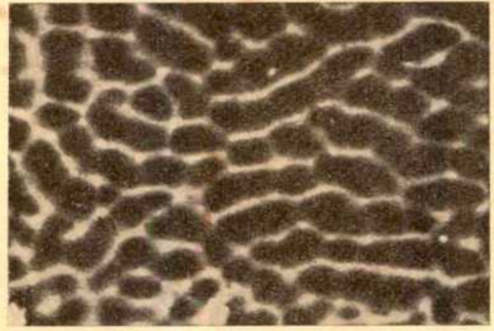

Fig. 1. Bénard cell patterns on silvered glass surface. × 2

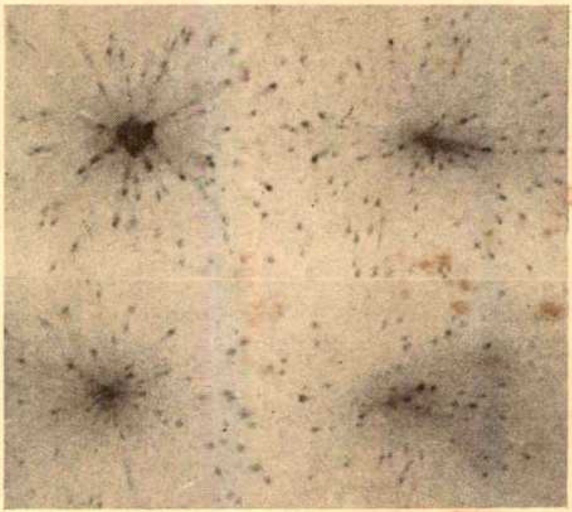

Fig. 2. Convection lines around poles of electro-magnet; 2,000 gauss field. × 3. Upper, north pole left, south pole right; lower, south pole left, north pole right

Patterns using a permanent magnet with large circular pole faces are shown in Fig. 3. The north pole lines are straighter and converge toward a central spot, whereas the lines at the south pole form at the periphery of the heated area and have greater curvature. There is a provocative similarity between these patterns and sunspot patterns. Especially interesting are sunspots that have mutual line patterns as shown by Alfven[1]. The magnetic field itself may

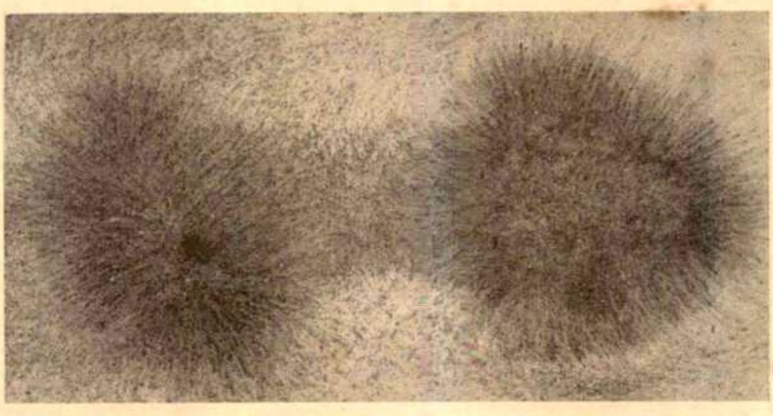

Fig. 3. Permanent magnet, north pole left, south pole right; 1,400 gauss field; pole faces 4 cm. diameter. × 0·6

have an inhibitive effect on the formation of the Bénard convection, as was recently demonstrated by Nakagawa[2]. Chandrasekhar[3] also points out that with motions at right angles to the magnetic field, the 'closing in' of the lines to produce the usual Bénard cell patterns becomes increasingly difficult. He also mentions that the lines around sunspots (photographed in hydrogen radiation) may be due to the inhibitive effect of their magnetic fields.

Relation between the Initial Instantaneous Extension in Creep and the Yield Stress and Coefficient of Work-hardening in Polycrystalline Metals

In the course of work on the creep of polycrystalline lead (99·99 per cent) under constant stress in the range 20–105° C., a full account of which is being prepared, it was found possible to measure the initial instantaneous extension with reasonable accuracy at the lower end of the temperature scale. At higher temperatures the period of low strain-rate, which intervened between the termination of the initial extension and the onset of the transient creep, diminished and the accuracy of measurement suffered in consequence. Nevertheless, as can be seen from Fig. 1, it was possible to establish that the tensile stress σ was related to the initial tensile strain ε by the work-hardening law characteristic of polycrystalline metals of cubic symmetry :

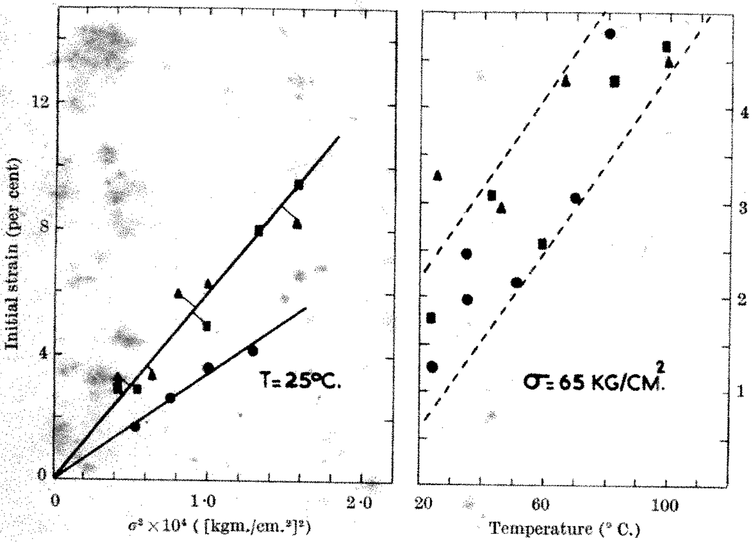

Fig. 1. Mean grain diameter : ●, 0·11 mm. ; ▲ 0·06 mm. ; ■, 0·04 mm.

$$\sigma^2/\varepsilon = \chi(T)$$

where $\chi(T)$ is the temperature-dependent coefficient of work-hardening.

Jacquet's electron-micrographic evidence[1] of the formation of dislocation 'pile-ups' at grain boundaries of slightly deformed alpha-brass, but particularly th uniformity of the spacing between adjacent pile-up suggested that the hardening of the brass was c the interaction type, treated theoretically by Mott which also leads to a parabolic strain-hardening law An attempt was therefore made to apply this theor of interaction-hardening to the results obtained i the present work.

If, to conform with the method of testing, th shear stress is replaced by $\frac{1}{2}\sigma$, and the tensile strai is put equal to the shear strain, Mott's theory give

$$\chi = G^2bn/\pi^2L$$

where $2L$ is the mean grain diameter, b the inte atomic spacing in the slip direction, G the shea modulus and n the number of dislocation in th pile-up. According to Mott,

$$n \simeq (2\pi L/Gb)\,\tau_y$$

where τ_y is the yield stress in shear of the undeforme metal. Since, judging from Jacquet's results, n doe not appear to be significantly dependent on L fo grain-sizes as used by him, and also in the work her discussed, it follows that τ_y should be approximatel inversely proportional to the grain-size. Furthe from the above relations,

$$\chi \simeq (2/\pi)\,G\tau_y$$

which is independent of n. Now, very slow cree in polycrystalline lead is observed at tensile stresses[3] o about 30 kgm./cm.², so that τ_y is less than 15 kgm. cm.² at 25° C., but must be greater than 3 kgm./cm.² which is the yield stress in shear for single crystals o high purity[4]. Therefore, taking $\tau_y = 10$ kgm./cm. and $G = 5 \times 10^4$ kgm./cm.², the last equatio yields $\chi = 3{\cdot}2 \times 10^5$ kgm./cm.² which is in satisfactory agreemen with the values obtained from th slopes of the lines in the left-han figure : $2{\cdot}8 \times 10^5$ kgm./cm.² fo $2L = 0{\cdot}11$ mm., and $1{\cdot}7 \times 10$ kgm./cm.² for specimens with grai diameters $2L = 0{\cdot}04$ and $0{\cdot}06$ mm Owing to poor resolution of th experimental results in the last two cases, separate χ-values wer not determined for these grain sizes. It is apparent, however that the ratio of grain sizes is close to the corresponding ratio of χ^{-1}-values. The value of n which is required to satisfy these results is of the order of 100 at 25° C., which is comparable with the mean value of the number of dislocations per pile-up as shown in Jacquet's micrographs. The comparatively high temperature-dependence of χ, indicated by the results in Fig. 1 (right), is of about the same magnitude as that of the yield stress in shear of lead single crystals in the same temperature-range[4].

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Wednesday, April 4

Institute of Fuel (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 5.30 p.m.—Mr. L. Clegg: "Fuel and Power Surveys".*

Institution of Electrical Engineers, Radio and Telecommunication Section (at Savoy Place, London, W.C.2), at 6.15 p.m.—Scientific Papers.

Society for Analytical Chemistry (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Mr. R. Hill: "The Determination of 4-Chloro-2-methylphenoxyacetic Acid in MCPA by a Differential Refractometric Method"; Mr. F. Franks: "Paper Chromatography with Continuous Change in Solvent Composition. Part 1. Separation of Fatty Acids. Part 2: Separation of Surface Active Agents".

Thursday, April 5

Institution of Electrical Engineers (in conjunction with the British Nuclear Energy Conference, at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. A. B. Gillespie: "The Control and Instrumentation of a Nuclear Reactor"; Mr. R. J. Cox and Mr. J. Walker: "The Control of Nuclear Reactors"; Mr. W. Abson and Mr. F. Wade: "Reactor Control Ionization Chambers"; Mr. G. E. Lockett: "Some Design Aspects of Nuclear Reactor Control Mechanisms".

Thursday, April 5—Friday, April 6

Institute of Physics, Education Group (at 47 Belgrave Square, London, S.W.1), at 10 a.m. daily—Conference on "The Teaching of Atomic and Nuclear Physics".

Society of Chemical Industry, Fine Chemicals Group (in the Auditorium, The Wellcome Building, 183–193 Euston Road, London, N.W.1)—Symposium on "Hypotensive Drugs and the Control of Vascular Tone in Hypertension".

Friday, April 6

Institution of Mechanical Engineers, Internal Combustion Engine Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 5.30 p.m.—Mr. G. B. R. Feilden, Mr. J. D. Thorn and Mr. M. J. Kemper: "A Standard Gas Turbine to Burn a Variety of Fuels".

British Institution of Radio Engineers, London Section (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6.30 p.m.—Discussion on "The Importance of Visual Aids in the Teaching of Advanced Radio and Electronic Engineering", opened by Mr. R. H. Garner.

Saturday, April 7

United Kingdom Committee for the World Health Organization of the United Nations (in the Beveridge Hall, Senate House, London University, Malet Street, W.C.1), at 2.30 p.m.—Meeting to celebrate "World Health Day". Principal Speakers: Sir Russell Brain, Bt., and Sir Andrew Davidson.

British Interplanetary Society (in the York Hall of Caxton Hall, Caxton Street, London, S.W.1), at 6 p.m.—Mr. J. Foley, Mr. E. White and Mr. R. Wilkins: "Power Supplies and Telemetry for Instrument-Carrying Artificial Satellites".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Biochemist, Senior Grade (with a first- or second-class honours degree) in the Pathological Department—The Secretary, Liverpool Radium Institute, 1 Myrtle Street, Liverpool 7 (April 7).

Lecturer or Assistant Lecturer in Applied Mathematics—The Registrar, The University, Leeds 2 (April 9).

Demonstrator (with a good honours degree in physiology or biochemistry) in Physiology—The Registrar, The University, Manchester 13 (April 10).

Research Engineers (with a good honours degree or corporate membership of one of the principal Engineering Institutes), for the development of plant manufacturing smokeless and metallurgical fuels—The National Coal Board, Coal Research Establishment, Stoke Orchard, near Cheltenham, Glos, quoting SS/236 (April 11).

Assistant Statistician (with a pass degree, diploma, or equivalent qualification, and preferably with a knowledge of both mathematics and horticulture (or botany)), for the examination and analysis of experimental data—The Secretary, East Malling Research Station, near Maidstone, Kent (April 14).

Lecturer in Physics—The Registrar, The University, Reading (April 14).

Lecturer (honours graduate in physics or chemistry) in Textile Chemistry—The Registrar, College of Technology, Manchester 1 (April 14).

Assistant Lecturer in Zoology—The Registrar, The University, Manchester (April 16).

Lecturer (with a good honours degree) in Chemical Engineering—The Registrar, King's College, Strand, London, W.C.2 (April 16).

Mathematician or Aerodynamicist (with a first- or second-class honours degree or equivalent, and preferably with a knowledge of airworthiness requirements and operating regulations) at the Ministry of Supply Headquarters in London, to assess the suitability of civil aircraft projects for commercial operations, including estimation of aircraft performance and economics of operation—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.99/6A (April 16).

Research Fellow in Economic Statistics—The Registrar, The University, Manchester 13 (April 16).

Lecturer (with a good honours degree in electrical engineering or physics) in Electrical Engineering with special reference to Electronics—The Registrar, King's College, Strand, London, W.C.2 (April 18).

Laboratory Superintendent for Pharmacology and Veterinary Physiology, and a Technician in Pathology, at Makerere College (University College of East Africa)—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (April 20)

Assistant Lecturer or Lecturer (preferably with qualifications in applied mathematics) in Mathematics—The Registrar, Trinity College, Dublin (April 21).

Lecturer (Grade II) in Mathematics at University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (April 23).

Lecturer (with teaching experience, and preferably a good honours degree in geography) in Education—The Secretary, The University, 38 North Bailey, Durham (April 28).

Lecturer or Senior Lecturer in Genetics—The Registrar, The University, Liverpool (April 30).

Lecturers in Experimental Physics—The Secretary of University Court, The University, Glasgow (April 30).

Professor of Experimental Physics at the University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, April 30).

Senior Lecturer in Pharmacology at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, April 30).

Research Physicist (with Ph.D. or equivalent in physics and experience in cryogenic research) in the Division of Physics, National Standards Laboratory, Commonwealth Scientific and Industrial Research Organization, Sydney, New South Wales, Australia, for experimental research in the Division's cryogenic group—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 770/116 (May 1).

Reader in Clinical Pathology at Guy's Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (May 2).

Reader or Senior Lecturer in Applied Mathematics at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong, May 7)

Lecturer (preferably with experience in the theory of machines and/or strength of materials) in Mechanical Engineering at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Sydney, May 15).

Assistant (preferably with experience in plant pathology) to the Mycologist at Cambridge, and an Assistant Regional Trials Officer (preferably with practical experience in crop production), at Leeds University Farm, Headley Hall, Yorks—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

Biochemical Technician in the Physiology Department of the Medical School, to take charge of the preparation of materials for biochemical classes for medical, dental and science students, and to assist if required in research work of a biochemical nature—Prof. A. A. Harper, Department of Physiology, The Medical School, King's College, Newcastle-upon-Tyne 1.

Biochemist (with a Ph.D. or its equivalent from a recognized university, and preferably a knowledge of manometric and tracer techniques) to study nutrition and metabolism of marine bacteria and various problems concerned with the biochemistry of fish—The Acting Director, Fisheries Research Board of Canada, Technological Station, Vancouver 2, B.C., Canada.

Chair of Civil Engineering—The Secretary-Treasurer, Royal Technical College, George Street, Glasgow, C.1.

Chemical Engineer (with a Master's or Bachelor's degree in chemical engineering, and preferably some research experience) to initiate engineering research on problems concerned with the processing of fish, and to assist in engineering work already in progress—The Acting Director, Fisheries Research Board of Canada, Technological Station, Vancouver 2, B.C., Canada.

Computor (woman, with good mathematical qualifications), to assist with scientific research in the Physics Department—The Assistant Secretary, University College London, Gower Street, London, W.C.1.

Crop Ecologist (with either (*a*) a good honours degree in botany, with postgraduate training in agriculture or agricultural botany, and a sound grasp of statistics, particularly those concerning crop sampling; or (*b*) a degree in mathematics with experience of statistical techniques and some knowledge of, and interest in, biometry or botany) in the Department of Soil and Land-Use Survey, Gold Coast, to collect yield data for various crops grown on different soils—The Director of Recruitment, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting BCD.79/13/03.

Electrical Engineers and Physicists (with a first- or second-class honours degree in electrical engineering or physics with a bias towards electronics, and preferably with experience of airborne radar systems) at a Ministry of Supply Establishment in Norfolk, for development and adaptation of radio equipment, pulse techniques, including aerials, power supplies and displays—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting D.105/6A/BN.

Laboratory Technician in Physics—The Clerk to the Governors, Mid-Essex Technical College, Market Road, Chelmsford.

LABORATORY TECHNICIAN (with appropriate qualifications, and preferably some training in biochemistry) IN THE CLINICAL PATHOLOGICAL LABORATORY—The Secretary, The National Hospital, Queen Square, London, W C.1.

LECTURER (specializing in palæontology–stratigraphy) IN GEOLOGY, and a LECTURER (specializing in petrology–mineralogy) IN GEOLOGY—The Acting Dean, College of Arts and Science, Baghdad, Iraq.

ORGANIC CHEMIST (Scientific Officer grade) (with at least a second-class honours degree with not less than a year's experience of research in organic chemistry, and preferably with an interest in the chemistry of natural products and/or microbiology) at the Colonial Microbiological Research Institute, Trinidad, to conduct research into chemical problems arising in the course of the Institute's programme, involving work on antibiotics and other products of micro-organisms, fermentation of the cocoa bean, plant polyphenols, etc.—The Director of Recruitment, Colonial Office, London, S.W 1, quoting BCD.208/209/04.

ORGANIC CHEMIST (with a degree in chemistry or biochemistry and postgraduate laboratory or research experience) AT THE LOW TEMPERATURE RESEARCH STATION, Cambridge, to work on the chromatographic analysis of potatoes in relation to blackening—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

PHYSICIST (with a good degree or equivalent, and a good knowledge of classical physics, with electronics) for work on problems of tension control of the yarns in lace manufacture; and a CHEMIST (with a good degree or equivalent in chemistry, and preferably some knowledge of textile chemistry) for work on problems of dimensional stability of lace fabrics—The Director, Lace Research Association, Glaisdale Drive West, Bilborough, Nottingham.

PHYSICISTS or CHEMISTS (with an honours degree) for work which covers a wide range of problems connected with the manufacture and use of ceramic materials—The Director of Research, British Ceramic Research Association, Queen's Road, Penkhull, Stoke-on-Trent.

SENIOR LECTURER IN PHYSIOLOGY AND PHARMACOLOGY at the Technical College, Bradford—The Director of Education, Town Hall, Bradford.

SENIOR LECTURER (with high academic qualifications, and able to teach physical chemistry up to B.Sc. special chemistry degree standard and also able to direct research) IN PHYSICAL CHEMISTRY—The Registrar, College of Technology and Commerce, The Newarke, Leicester

PERMUTIT

ION EXCHANGE MATERIALS

The use of Permutit Ion Exchange Materials in many roles distinct from water treatment, has resulted in the development of numerous new industrial processes giving improved results and lower running costs. Some materials now available are:—

Zeo-Karb Na. A sulphonated coal product containing both strong and weak acid groups.

Zeo-Karb 215. A nuclear sulphonated phenol resin containing also hydroxyl groups.

Zeo-Karb 225. A unifunctional cross linked sulphonated polystyrene resin in bead form of high capacity and exceptional chemical and physical stability.

Zeo-Karb 226. A unifunctional cross linked methacrylic acid resin in bead form containing only carboxyl groups as the ion active groups.

De-Acidite E. A high capacity anion exchange material of medium basicity.

De-Acidite FF. A unifunctional very highly basic anion exchange resin in bead form based on cross linked polystyrene and containing quaternary ammonium groups.

De-Acidite G. A unifunctional weakly basic anion exchange resin in bead form based on cross linked polystyrene and containing diethylamino groups.

De-Acidite H. A material similar to "De-Acidite G" but containing dimethylamino groups.

Bio-Deminrolit. A mixed cation and anion exchange resin for demineralisation in a single column.

Decalso F. A synthetic sodium aluminium silicate suitable for the separation and concentration of vitamins and hormones.

Decolorite-Asmit. A resin of high porosity for removing colour from solutions.

Permaplex C-10. A highly selective cation exchange resin membrane containing SO_3H groups.

Permaplex A-10. A highly selective anion exchange resin membrane containing quaternary ammonium groups.

For full technical information please write to: THE PERMUTIT COMPANY LIMITED. Head Office and Laboratories: Dept. V.H.92, Permutit House, Gunnersbury Avenue, London, W.4. Telephone: CHIswick 6431

Permutit Ion Exchange Materials — Made in Britain by British Labour

ENBEECO

PROFILE PROJECTOR

(MARK III)

For QUICK and ACCURATE INSPECTION of SMALL PARTS

The Enbeeco Profile Projector is an extremely moderately priced apparatus which accurately projects magnified profiles of small parts, such as screw threads, small components, etc., on to a screen which is an integral part of the projector. Small objects are placed on the micrometer actioned platform positioned at right-angles to the optical axis of the projection lens, and by means of suitable aluminised mirrors the image of such parts is thrown on to the instrument screen. The screen takes the form of two sheets of glass approximately 9″ × 8″ between which a sheet of Ethulon tracing film is sandwiched, permitting an enlarged drawing of the profile being made on the tracing material so that the projector can be used as a comparator. Two models are available, one giving magnifications of ×10 and ×15 and another giving magnifications of ×25 and ×50.

Literature gladly sent upon request.

LECTURES AND COURSES

UNIVERSITY OF BIRMINGHAM
DEPARTMENT OF PHYSICS
M.SC COURSE IN RADIOACTIVITY

A course of lectures and practical work in general radioactivity, leading to the degree of M Sc. by examination has been instituted in the Physics Department. The course is suitable for honours graduates in physics wishing to obtain special experience in radioactive techniques including radiochemistry. Graduates in subjects other than physics, and graduates in physics who have not obtained honours will also be considered for admission to the course. A university scholarship covering fees and maintenance will be available in connection with the course. The course lasts for one full academic year The fee is £71 1s.

Applications for admission to the course, starting in October, 1956, should be made to the Registrar, the University, Birmingham, 15, as soon as possible.

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY
SUMMER SCHOOL IN
THE PHYSICAL CHEMISTRY OF PYRO-METALLURGY
Monday Afternoon to Friday, September 10-14, 1956

The Course, which is being held by the Nuffield Research Group in Extraction Metallurgy, will consist of lectures, experiments and discussions on the physical chemistry of systems of metallurgical interest at high temperatures As numbers are limited early application is advisable

Full details from the Registrar, Imperial College, Prince Consort Road, London, S.W.7.

THE POLYTECHNIC
309 REGENT STREET, W 1
DEPARTMENT OF MATHEMATICS AND PHYSICS

A full-time course of four years' duration for The Polytechnic Diploma in Physics will commence in September, 1956. This diploma carries full exemption from the examination requirements for the Graduateship of the Institute of Physics (Grad Inst P) Entrants should be at least 16 years of age and have attained the standard of the ordinary level of the G C E examinations in appropriate subjects Students who have reached the advanced level will be exempt from the first year of the course

A prospectus giving full details of the course may be obtained on application to the Director of Education.

OFFICIAL APPOINTMENTS

The engagement of persons answering these advertisements must be made through a Local Office of the Ministry of Labour or a Scheduled Employment Agency if the applicant is a man aged 18 to 64 inclusive, or a woman aged 18 to 59 inclusive, unless he or she, or the employment is excepted from the provisions of the Notification of Vacancies Order, 1952

BIOCHEMIST

Applications are invited for a position as Biochemist to study nutrition and metabolism of marine bacteria and various problems concerned with the biochemistry of fish Knowledge of manometric and tracer techniques is desirable, and a Ph D. or its equivalent from a recognized university is required

Send details regarding training, publications references and salary required to the Acting Director, Fisheries Research Board of Canada, Technological Station, Vancouver, 2, B C.

LIVERPOOL RADIUM INSTITUTE MANAGEMENT COMMITTEE
1, MYRTLE STREET, LIVERPOOL, 7

Applications are invited for the post of Biochemist (Senior Grade) in the Pathological Department of the Institute First- or second-class honours degree essential. The appointment includes both routine hospital biochemistry and work connected with the investigations into the uses of radioactive isotopes in medicine Ample opportunity and facilities are available for work of a research nature into the problems of the biochemistry of neoplastic disease Salary and conditions of service in accordance with the recommendations of the Whitley Council

Applications, stating age, qualifications and experience, together with the names and addresses of two referees to reach the Secretary by April 7, 1956

THE ROYAL SOCIETY
SMITHSON RESEARCH FELLOWSHIP

The Committee representing the Royal Society and the University of Cambridge invites applications for the Smithson Research Fellowship This Fellowship is open to British subjects, including subjects of the Empire, without distinction of sex In accordance with the bequest of the late Mr E W Smithson, the object of the Fellowship is to promote "research in natural science, with a view to the discovery of new laws and principles, rather than the exploitation of what is known" Preference will be given to candidates not more than thirty-five years of age. The appointment will be made for four years with effect from October 1, 1956, but may in exceptional circumstances be renewed by the Committee for further periods of one year each The stipend will be at the rate of £1,000 a year and the Fellow will be required to contribute to a superannuation scheme Normally, the Fellow will be required to carry out his research in the University of Cambridge and, if not already a member of that University, to acquire membership

Applications must be received at the offices of the Royal Society not later than May 1, 1956 Each applicant must state his age and qualifications, the nature of the research in which it is proposed to engage, and particulars of any other grants or endowments which he holds The application should contain the names of two persons willing to act as referees who can give confidential information to the Committee concerning the applicant and his qualifications. Applicants from distant parts of the Empire should, where possible, nominate referees resident in Great Britain. Open testimonials are not desired and will not be considered. Printed copies of the regulations and forms of application can be obtained from the Assistant Secretary of the Royal Society, Burlington House, London, W 1

UNIVERSITY OF HONG KONG

Applications are invited for the newly-established post of Reader in Mechanical Engineering in the Department of Civil Engineering Salary (superannuable): £2,500 a year, together with an expatriation allowance of £300 a year if applicable The equivalent of income tax in the Colony is comparatively low Applicants must be graduates of British universities and Corporate Members of the Institution of Mechanical Engineers, with teaching experience at university level First class sea passages are provided for expatriate staff and their families on first appointment and leaves.

Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C 1 The closing date for the receipt of applications, in Hong Kong and London, is May 7, 1956.

MANCHESTER COLLEGE OF TECHNOLOGY
(FACULTY OF TECHNOLOGY IN THE UNIVERSITY OF MANCHESTER)
APPOINTMENT OF LECTURER IN TEXTILE CHEMISTRY

The Governing Body invites applications for a Lectureship in Textile Chemistry in the College of Technology with the title and status of Lecturer in the University of Manchester Candidates should be honours graduates in physics or chemistry The Lecturer will be expected to carry out research work of a physico-chemical nature connected with bleaching, dyeing and printing, for which good facilities are available Salary· £650 per annum, rising by annual increments of £50 to £1,350 per annum Commencing salary according to qualifications Superannuation under the F S S U. Family allowances.

Conditions of appointment and form of application may be obtained from the Registrar, College of Technology, Manchester, 1. The last day for the receipt of applications is Saturday, April 14, 1956

B V. BOWDEN,
Principal of the College

ENGINEERS AND PHYSICISTS (MINIMUM age 26) required by Ministry of Supply, Rocket Propulsion Department, Westcott, Bucks, for research and development on rocket motors and propellants, instrumentation and recordings; investigations on high speed flow and heat transfer problems Qualifications: H S C (Science) or equivalent but pass degree or H N C may be an advantage. Salary within Experimental Officer range £745 to £920—Application forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S W.1, quoting A 105/6A/BN. Closing date April 21, 1956.

UNIVERSITY OF EDINBURGH AND HERIOT-WATT COLLEGE
JOINT DEPARTMENT OF CHEMICAL TECHNOLOGY AND CHEMICAL ENGINEERING

Applications are invited for either a Lecturesh or an Assistantship. Lectureship: The initia salary will be at a point on the scale £700 by £5 to £1,350 per annum, according to qualificatio and experience. It is hoped to appoint a ma who will be active in some field of chemical e gineering research of his own choice Assistan ship: The salary will be £550 by £50 to £650 pe annum. Teaching duties will not be heavy and th Assistant will be encouraged to carry out researc for a Ph D. Both posts will be pensionable, unde the F S S.U., and family allowance is payabl where applicable The successful candidate w be expected to take up duty on October 1, 195 Applications will be considered from chemic engineers, physicists, chemists or mechanical e gineers, or from mathematicians who have e perience in applied science

Further particulars may be obtained from th undersigned, with whom applications (ten copies giving the names of two referees, should be lodge not later than April 16, 1956

JOHN MACPHERSON,
Assistant Secretary to the Universit

UNIVERSITY OF LIVERPOOL
FACULTY OF SCIENCE

Applications are invited for the post of Le turer or Senior Lecturer in Genetics The initi salary for (a) a Lecturer will be within the rang £650 to £1,350 per annum, according to quali fications and experience; or (b) a Senior Le turer will be £1,400 by £50 to £1,600 per annu

Applications, stating age, academic qualific tions and experience, together with the names o three referees, should be received not later tha April 30, 1956, by the undersigned, from who further particulars of the conditions of appoin ment may be obtained

STANLEY DUMBELL
Registra

UNIVERSITY OF LIVERPOOL

Applications are invited for the post of Assis tant Lecturer or Lecturer in the Department o Inorganic and Physical Chemistry Candidat should have special qualifications in either in organic or physical chemistry The initial salar for an Assistant Lecturer will be £550 per annum or in special circumstances £600 per annum, th initial salary for a Lecturer will be within th range £650 to £850 per annum, according t qualifications and experience.

Applications, stating age, academic qualifica tions and experience, together with the name of three referees, should be received not late than April 14, 1956, by the undersigned, fro whom further particulars of the conditions o appointment may be obtained

STANLEY DUMBELL,
Registrar

UNIVERSITY COLLEGE OF WALES
ABERYSTWYTH

Applications are invited for the post of Assist ant Lecturer or Lecturer in the Department o Applied Mathematics, with qualifications i applied mathematics or theoretical physics

Applications, giving the names of two person to whom reference may be made, should be sen to the Registrar, from whom further particular may be obtained, not later than April 14, 1956

UNIVERSITY OF CAMBRIDGE
A.E I FELLOWSHIPS

Applications are invited for two Associate Electrical Industries Fellowships, tenable fro October 1, 1956, one in the Department o Physics and one in the Department of Engineering Stipend within the range £900 to £1,400 a yea with family allowances and F S S U. benefits

Particulars may be obtained from the Secretary General of the Faculties, The Old Schools, Cambridge, by whom all applications must be receive not later than May 31, 1956

CHEMICAL ENGINEER

Applications are invited for a position a Chemical Engineer to initiate engineering researc on problems concerned with processing of fish and to assist in engineering work already i progress Applicants should possess a Master's or Bachelor's degree in chemical engineering, and preferably possess some research experience

Send details regarding training, references and salary required to the Acting Director, Fisheries Research Board of Canada, Technological Station, Vancouver, 2, B C

SCIENCE AND TECHNOLOGY IN DEFENCE

THE recently issued Statement on Defence* is largely a progress report on what has been done in Britain to translate into a defence programme the policy outlined in last year's White Paper. Although during the summer of 1955 there was reason for hoping for a genuine relaxation in international tensions and for the growth of tolerance and understanding between the nations of the free world and those under Communist control, this hope has been disappointed. It remains necessary for the Western democracies to maintain their defensive strength until such time as a true understanding of Western policies can make its impact on the Soviet people.

The appreciation of the economic factors given in the White Paper is realistic and does at least point to the fundamental question: How much can Britain afford to spend on defence? It is not simply the effect of high expenditure on defence on the general level of taxation. Production for defence falls in the main upon the metal and metal-using industries, which supply about half the exports of Britain and are of great importance in re-equipping British industry, thus playing a vital part in strengthening the balance of payments. Moreover, the maintenance of British forces overseas involves a heavy direct charge on the balance of payments.

It is something to find at last frank acknowledgment that the claims of defence research must be balanced against the competing claims on the limited resources of scientific man-power, quite apart from the fact that the size of the Services themselves inevitably affects the man-power available for civil industry. This may be due to the fact that the Services have been able to recruit only about one-half the graduates they need; but it may be also due to the growing realization that the new defence policy laid down last year, and in particular the concentration on improved weapons, makes a strong research and development effort essential. The Government has come within sight of realizing the fundamental importance of science in the defence effort of Britain and, in particular, of directing the limited resources wisely. It is admitted that there have been signs that the research and development have been overloaded and resources dissipated instead of being concentrated on a limited number of projects of the highest strategic importance. The whole programme is now being thoroughly re-examined in order to ensure a proper balance between the resources available and the projects to which the highest priority should be attached.

It is on the selection of those projects and in its analysis of the strategic factors that the White Paper is weakest and most open to criticism; and strategic weakness could frustrate the purpose of the review of the future development of the Services on which the Government has been engaged. Admittedly, at a time of rapid technical advances, a point will be reached beyond which it is impossible to plan because any conclusions will be based on guesswork. Nevertheless, even when the Government confines its review to probable developments over the next seven years, unsound strategic objectives can defeat the purpose of a review designed to provide the Services with reasonably long-term plans on which their production, training and building programmes can be based, to ensure that the reduction in man-power to about seven hundred thousand proposed by March 1958 is achieved with the least military risk, and that the cost of defence in terms of man-power, materials or money does not overload the economy.

Before considering the strategic aspect, this research and development programme may be examined more closely. The financial provision for research and development in 1956–57 has been increased to provide for new weapons of greater complexity and higher quality; expenditure on production and research is now estimated at £787,580,000 gross, against appropriations-in-aid of American aid receipts amounting to £224,930,000. This figure includes the cost of development work undertaken by industry under contract, and the purchase of stores and equipment for research and development establishments, and is £58,170,000 less than in 1955–56, or 37·5 per cent of the £1,498,700,000 net, compared with 41·5 per cent of the £1,494,200,000 net in 1955–56. The White Paper, in stating that the financial provision for research and development has been increased, gives little idea, however, where the increase has been made; and in the debate in the House of Commons on February 28, Sir Walter Monckton, Minister of Defence, merely gave the total figure as about £200 million. Development of some of the more conventional weapons has been cut out or reduced, though some research and development are continuing on them; but it is clearly the new and technically very complex projects, particularly those associated with the deterrent aspect, which are making increasingly heavy demands on the resources of Great Britain.

The White Paper claims that the whole programme is being kept under review with the dual aims of maintaining the right balance between the newer and the older kinds of development projects, and of ensuring that the effort which is being devoted to defence research and development is deployed to the best advantage. It is also recognized that, within the programme as a whole, the effort on research as distinct from development must be maintained, and that the future effectiveness of the British Armed Forces depends primarily on the wise direction and quality of the research effort. Moreover, apart from the need for maintaining specific research aimed at solving immediate problems, long-term research is of increasing importance as techniques become more complicated.

Admittedly the balance between research and development costs and expenditure on the Armed

---

* Statement of Defence, 1956. (Cmd. 9691.) Pp. 32 (London: H.M. Stationery Office, 1956.) 1s. 3d. net.

Forces in general is very delicate; and investment in research and development is bound to be heavy with the rapid advance in science and technology. Nevertheless, the indications of the extent of that effort given in the White Paper do suggest some doubts as to whether, over the past few years, the right projects have been selected and whether that effort is still being too widely diffused. Work on the development of a variety of nuclear weapons, for example, continues to expand, and in relation to home defence the importance of continuing and expanding research into the problems of nuclear warfare, and into the most effective and practical methods of dealing with them, is stressed. Many factors of fundamental importance remain obscure, and the danger of misdirected effort here is admitted. Again, particular emphasis is placed on the development of the ballistic rocket and on the *V* bomber aircraft as a deterrent to aggression. Progress is being made in the development of guided missiles for each of the Services, and increasing effort is being devoted to the solution of the problems of flight at high supersonic speeds, including the problems of take-off from, and landing on, existing airfields and aircraft carriers. Two experimental high-speed submarines should be completed next year, and considerable advances have been made in increasing the range of submarine detection and in associated weapons, while the first guided-weapons trial ship should be in operation next summer.

These are only some of the research and development projects indicated by the White Paper; but they illustrate sufficiently the way in which strategic considerations determine the shape of the research and development effort in Britain. Still more, they indicate the importance of the right selection of objectives; and although reference is made to the continuance of close co-operation with the United States, particularly on guided weapons, they raise also the question whether, in deciding the magnitude and nature of research and development, sufficient regard has been paid not merely to resources but also to the possibilities of co-operation with other countries of the Western alliance. The two main criticisms of the British defence policy and programme are, in fact, whether the thinking about priorities has been sufficiently fundamental and whether, in selecting projects, account has been taken not simply of the right priorities but also of the full possibilities of specialization in arms and functions among the countries of the Western alliance. In particular, may not some of the British research and development projects be wastefully duplicating American work?

Before considering such criticisms, however, it is as well to look at the strategic considerations as presented in the White Paper. First, it is suggested that the primary objective must be to prevent war by the maintenance of the Allied deterrent. We have also to be prepared for the continuance of the 'cold' war—the constant and world-wide threat of Communist penetration short of direct military aggression. Equally, we have to be prepared for the outbreak of localized conflicts on a scale short of world war; nor can the possible use of nuclear weapons in such limited wars be ignored.

Accordingly, the forces required to support present British strategy have a fourfold role to fulfil. They must contribute to the Allied deterrent, commensurate, it is suggested, with Britain's standing as a world power. They must play their part in the 'cold' war. They must be capable of dealing with outbreaks of limited war, should they occur. They must also be capable of playing their part effectively in a world war, should it break out, and this involves full co-operation with the civilian authorities and an organization for home defence which can be readily expanded or adapted as changes in the international situation or the development of new weapons may require.

Sir Walter Monckton, in opening the debate in the House of Commons on February 28, acknowledged the importance of getting the priorities right. The resources available for defence will be stretched to the utmost in meeting even essential needs, and to attempt to do more would impose an intolerable strain on the national economy and thus defeat its own ends. Sir Walter said Britain has never been able to do all that is required for full insurance: something has always had to be left out, and the real question is what is the calculated risk to be taken.

All this was common ground among speakers in the debate. Differences of opinion arose over the nature of the calculated risks, and it is not easy for anyone, denied the full knowledge which the Government alone possesses, to pronounce on the soundness of the particular projects on which the Government has decided to concentrate the limited resources of the nation. Indeed, even with that full knowledge, in an era of rapid technical advance there is, as Sir Walter admitted, an element of guesswork in the Government's own decisions.

In spite of this, however, a certain amount of evidence was advanced during a debate, which generally reached a high level, to suggest that during the past ten years the selection of priorities has not been sound, even when it is remembered that in some fields the choice has not rested entirely with Britain. The debate, however, was valuable not so much for suggesting, subject to the limitation already noted, what the correct priorities might be, as for stressing, first, the need to raise defence above political party issues and to ensure some continuity in the office of Minister of Defence: and, secondly, for indicating some of the factors which should determine the choice of objectives.

One criticism advanced of the Government's defence policy is whether sufficient attention is being given to the possibilities of co-operation or specialization of function with the other countries of the Western alliance. Of this, Sir Walter Monckton observed that there is a continual exchange of information and co-operation in other ways between the United States and Britain, and indeed that there are mutually benefiting arrangements with the United States for the exchange of military information of all sorts, including special arrangements for collaboration in the vital field of guided missiles. He thinks, however, that in practice there are definite limits to the extent to which the British research and development effort and that of the United States can be made to coalesce. Apart from the dollar difficulty, there are sometimes practical difficulties in making equipment of American design in Britain and incorporating it in British ships, aircraft, etc. British policy, Sir Walter suggested, should be to make the fullest use of the collaboration agreement we have with the United States and other countries to avoid duplication of research and development, but it is also necessary to continue with research and development ourselves over a wide range of projects. Sir Walter admitted that we shall have to be more selective in re-equipping our Forces. Mr. R. R. Stokes's comment here is significant: "We cannot go on behaving in a nuclear age as if nothing much had happened. We need new thinking".

That is particularly true in regard to the policy of graduated deterrence which has been urged on the Government and which was advocated by Prof. P. M. S. Blackett in a lecture at Trinity College, Cambridge, on February 24, when he made some outspoken criticisms of the confusion of thought in planning defence policy. Prof. Blackett said that, while the White Paper contains some sound proposals, it does not reflect the doubts and criticisms which are now being raised, not only as to civil defence but also as to defence policy in general. He thinks that the present confusion arises from the failure of those planning defence to adapt themselves to the change in the comparative strength in nuclear weapons of the East and West since 1950, and urged that some clear definition of the circumstances in which the nations are prepared to use atomic weapons and some definite distinction between their strategic and tactical use are greatly needed.

Sir Walter referred briefly to this matter at the close of his speech, but no more than to indicate that the Government is thinking again as to the possibility of distinguishing between tactical and strategic weapons. Indeed, so far from advocating adoption of a policy of graduated deterrence, he thinks there are solid grounds for believing that, even if the policy is right in itself, it is unlikely to be adopted by other parties to the agreement. Sir Walter leans towards a comprehensive scheme of disarmament, but in doing so he largely shied away from the questions and decisions which should determine the projects on which our resources should be concentrated for effective defence.

Apart, however, from this question of the right choice of projects, there is also the question of the general deployment of scientific and technical resources in Britain. It is admitted in the White Paper, and was recognized in the debates of February 28 and 29, that defence research and development effort make heavy demands on industry in Britain as well as on scientific and technical man-power. The public is not, however, given anything like the information in the White Paper or elsewhere for an outside judgment to be formed as to whether or not that effort is in danger of distorting the national economy or the balance of scientific and technical effort. Concern has sometimes been expressed, for example, as to the effect on the balance of research of the efforts in nuclear physics and the development of nuclear energy, not merely for weapons but equally for peaceful purposes; but there is at present no means of judging how effective a safeguard the organization of defence research in Britain under the Defence Research Policy Committee can provide against such distortion.

It would be reassuring, moreover, if the White Paper had touched on the bearing of technical education in Britain both on recruitment to the Services and on the equipment of the Services to fulfil their function. This, too, is an aspect of the general man-power situation of the country; for defence requirements have to be considered in relation to scientific and technical education, just as they have in relation to scientific and industrial research. Nor will these needs be met effectively except as part of an adequate educational policy for the nation as a whole, which takes full account of particular shortages such as that of science teachers and seeks to meet them by realistic and fundamental measures rather than by expedients which merely create difficulties and undesirable repercussions elsewhere. Any expansion of scientific and technological man-power in Britain, and even in technical man-power, is a long-term process; as Prof. Blackett remarked, defects in an educational system are not quickly repaired, nor is there any easy recovery from false economies in research in the past.

Accordingly, it is important not merely that these resources should be distributed wisely, but also that the best possible use should be made of them where they are deployed, that skilled and highly trained men should not be employed where those less trained would be equally effective, and that neither professional inhibitions nor restrictive practices on the part of employers or trade unions should hinder the development of the nation's full productive capacity. It is these factors which, as much as anything, will determine whether Britain can continue to devote to defence purposes some two-thirds of its expenditure on scientific research (on Mr. John Strachey's estimate); and they give a point to Mr. G. Brown's plea for a further look at the way in which defence research is organized departmentally—the Minister of Supply's assurance that there is little duplication in research was rather bald. There is the additional point that, in the field of defence as elsewhere, the effectiveness of applied research depends on the way it is administered and the degree of understanding of research methods and people, as well as of the problems to be solved, shown by those responsible for that administration. It is always possible to learn from others, and there are more than a few points, for example, in the papers presented last September in the United States at the ninth annual conference on the administration of research at the North Western University Technological Institute, which deserve consideration in this connexion; particularly relevant is Mr. R. A. Morgan's discussion of research relationships between government and the university, in which defence research was specifically considered.

More even than last year, the latest Statement on Defence puts the whole question of defence and defence research in its proper economic as well as its strategic or political context. The implications are not always pursued or examined and the priorities may be challenged. Though the Government can perhaps be charged with attempting too much and spreading the nation's resources too widely, the first duty of the scientist or technologist is not to attempt to point out what those priorities should be ; rather he should stress the relation of the defence effort, and especially that on research and development, to the economic effort generally, and put in perspective the implications of this for the nation's industrial and scientific research effort as a whole, for its technological and scientific man-power and for its educational system.

IMPACT OF SCIENCE ON RELIGION

Modern Science and Christian Beliefs

By Dr. Arthur F. Smethurst. Pp. xx+300. (London: James Nisbet and Co., Ltd., 1955.) 21*s*. net.

DR. A. F. SMETHURST has set before himself an ambitious aim. He surveys the whole range of natural science and considers its bearing on Christian belief with the object of enabling any educated reader to form a reasonable opinion on the subject. He has succeeded in a surprising degree and has written a book which is always lucid and readable ; it should help to enlighten many Christians on the present state of scientific thought and perhaps, too, some scientists on modern Christian theology. It is difficult to review such a book, because few could claim so wide a knowledge of the various branches of science, together with the equipment of a theologian, as that possessed by the author—and certainly I am not one of the few.

It is inevitable that not all the sections of the book should be of equal interest, and it will be possible here only to indicate its scope and to direct attention to some controversial points. Dr. Smethurst deals with the inherent limits of scientific knowledge on lines which are familiar, laying stress on the fact that individuality and value seem to be excluded from its investigations. He argues that the Christian belief in God prepared the way for the rise of natural science. In this, he agrees with many other eminent thinkers; but one may, perhaps, hesitate to hold that the belief was an indispensable preparation without which science could not have come into existence. It is always rash to dogmatize on what could or could not have happened, had circumstances been other than they were ; and it is enough for Dr. Smethurst's case to state, what is obviously true, that the Christian belief in God was, in fact, one of the conditions in which science came into being. Dr. Smethurst contends forcibly, and surely reasonably enough, that recent advances in physics and astronomy, so far from tending to make theism less easy to accept, have had the opposite effect, and the theistic view finds more support from modern cosmology than it could ever have from the scientific theories of the end of the nineteenth century. When the reader comes to the chapters on biology and psychology he is in the thick of the conflict.

Dr. Smethurst may be congratulated on his firm repudiation of fundamentalism in all its forms and his clear statement of the general evidence for the fact of evolution. He argues that evolution bears the marks of divine purpose and cannot be interpreted adequately unless we see in it the work of creative Spirit. But the problem of evil cannot be ignored, and the author does not evade the issue. In this connexion he has a good word to say for the devil—not, one hastens to add, as a character, but as a hypothesis. His view might be described as a relative and temporary dualism. Support can, of course, be adduced for this conception from the New Testament, and it has *prima facie* an apparent agreement with the facts of experience. Dr. Smethurst is well aware of the philosophical and theological difficulties which would have to be met, but no doubt lack of space prevents him from going deeply into them. No author can be blamed for not producing a final solution of the crux of theism—the problem of evil—but a further development of Dr. Smethurst's thesis would have been welcome.

The chapter on psychology is one of the best in the book, characterized by fair and balanced presentation of the chief theories. Freud's contribution is recognized and duly appraised, while the criticism of his view on the nature of religion is definite and well-argued. The value of the book is considerably enhanced by four long appendixes on logical positivism, dialectical materialism, existentialism and the problem of the communication of the Gospel in a scientific age. It is to be hoped that Dr. Smethurst's book will be read by many Christian fundamentalists and by many 'dyed in the wool' agnostics. Both classes of readers will find much to think about.

W. R. MATTHEWS

RADIOACTIVE TRACER TECHNIQUES IN BIOLOGY

Radioisotopes in Biology and Agriculture

Principles and Practice. By C. L. Comar. Pp. xiii+481. (London: McGraw-Hill Publishing Company, Ltd., 1955.) 67*s*. 6*d*.

THE success of radioactive tracer techniques has nowhere been more spectacular than in the biological sciences. The application of radioisotopic techniques to biology and physiology has already resulted in far-reaching advances and continues to develop so rapidly that some knowledge of the possibilities and limitations of tracer methods is now essential to every worker in these sciences. The publication of this informative and factual book, written primarily for the biological student and investigator, is therefore particularly welcome.

The author gives a clear and comprehensive survey of the present situation with regard to radioactive tracer techniques in biology. An excellent balance between principles and practice is maintained throughout, and comprehensive references on all aspects of the subject are quoted. The book will be of particular value to the research worker who wishes to apply tracer methods to his own problem. Its major weakness lies in the omission of an adequate account of the elements of radioactivity physics, and the newcomer to the subject will need to turn to elementary text-books of physics for a correct understanding of these fundamental principles without which he will not be fully equipped to undertake tracer investigations.

The book opens with an excellent account of the general principles on which different types of tracer studies are based, with examples drawn from a wide variety of biological investigations, and includes a particularly valuable treatment of the kinetics of biological systems as studied by radioisotopic methods. The limitations imposed by chemical effects, radiochemical impurities, radiation effects and isotopic effects are clearly defined. Then follows a practical account of the measures necessary to protect personnel against radiation, including suggested working rules for use in radiochemical laboratories. It is unfortunate that the book was written too early for the inclusion of a summary of the 1955 Recommendations of the International Commission on Radiological Protection, and it is to be hoped that this omission will be made good in future editions.

A useful chapter outlines plans for typical laboratories for radioactive work and gives much practical information regarding methods of administration of active materials to both animals and plants and methods of sample collection. The section devoted to techniques for the radioactive assay of biological samples is less successful owing to the inadequacy of the physical treatment. While the author cannot be criticized for not giving a detailed discussion of the scalers and other electronic equipment used in assay work, the omission of a satisfactory description of the fundamental properties of the Geiger–Müller counter, scintillation counter and ionization chamber and of the mechanism of radioactive decay is difficult to justify.

A detailed summary of the properties of selected radioisotopes is given, with examples of investigations illustrating the procedures, equipment and precautions necessary for their use. The data presented for each isotope include the specific activity available, the minimum detectable activity using different assay methods, and figures relating to radiation protection. While they form a useful guide, these data should be accepted with some reserve in view of the present rapid improvement in technique. The specific activities listed are those obtainable from the Oak Ridge reactor in the United States, and do not necessarily apply to preparations obtained from other sources. It may also be noted that the protection data are in some cases at variance with the latest Recommendations of the International Commission on Radiological Protection. A select bibliography accompanies the information relating to each isotope.

The final chapters discuss the allied techniques of autoradiography, paper chromatography, ion exchange and activation analysis which play so important a part in tracer studies. These chapters are all excellent. Their scope is much wider than the limited field of radioactive tracer methods, and they give a clear and concise introduction to these fascinating techniques.

The general format and production maintain the high standard expected from the publishers. This book, while not to be regarded as a standard work of reference, will form a valuable addition to the library of the biological research worker.

E. H. Belcher

HANDBOOK OF ORGANIC COMPOUNDS

Organic Solvents

Physical Properties and Methods of Purification. On the basis of the First Edition by Arnold Weissberger and Eric S. Proskauer. Completely revised Second Edition by John A. Riddick and Emory E. Toops, Jr. (Technique of Organic Chemistry—Vol. 7. Edited by Arnold Weissberger.) Pp. vii+552. (New York: Interscience Publishers, Inc.; London: Interscience Books, Ltd., 1955.) 8.50 dollars.

THE statement on the dust cover claims that this volume provides "a guide and reference book for everyone engaged in synthetic organic work, in the study of reaction mechanisms, and in the study of non-aqueous solutions and titrations". This provides a better description of the contents of the book than the main title, since the volume does not, in fact, record the solvent properties of any compound.

The physical properties and numerical values tabulated can be grouped into four main types: values useful for the identification of pure substances and as criteria of purity (for example, boiling points, melting points, etc.); values useful in connexion with physico-chemical measurements (for example, ebullioscopic constants, etc.); properties useful for the study of solute systems (for example, electrical conductivities, spectra, etc.; no spectra are shown, however, but references are given to sources); and properties important for the handling and storing of solvents (for example, flash points and toxicities). The various constants are listed under the names of the compounds; but there are also tables of boiling points, freezing points, dielectric constants and dipole moments with the properties arranged in order of increasing magnitude. A chapter is devoted to a discussion of criteria of purity, drying techniques and determination of water. A large section consisting of 163 pages which describes various purification procedures for each compound is followed by a bibliography, a list of 2,169 references to the literature and an index.

The occurrence of *cis*- and *trans*-isomers of certain cyclic compounds has given the compilers of this volume a great deal of trouble. Thus, although it is stated on p. 314 that "Decahydronaphthalene from different sources will show considerable variation in composition of the *cis*- and *trans*-isomers", the results of very precise measurements made on unspecified mixtures of isomers are presented on p. 68. Similarly, the properties of 2-, 3- and 4-methylcyclohexanol are tabulated, although there is no indication whether the values quoted refer to the *cis*- or *trans*-isomers or to a mixture of these materials.

The molecular weights given are not now correct to the number of figures quoted, because the 1953 International Atomic Weights were not employed. Thus, the molecular weight of cyclopentane should be 70·135 and not 70·130 as printed. Some of the constants appear to have been recorded with a much greater precision than the experimental results warrant. For example, several flash-points are given to the nearest 0·1 deg. F., whereas this constant is rarely known to within 5 or 10 deg. F. Thus, the flash-point of *n*-heptane is quoted as 20·6° F., whereas values ranging from 25 to 63° F. are given in the pamphlet "Fire-Hazard Properties of certain Flammable Liquids, Gases and Volatile Solids"

(National Fire Protection Association, Boston, 1946), which recommends 25° F. as the selected value. Errors in the structural formula of the following compounds were noted (page numbers in brackets): 3-methylpentane (55); 2,2-dimethylbutane (56); 2,2,3-trimethylpentane (65); *p*-xylene (76); 2-pentanol (99); 3-methyl-1-butanol (101); methylal (130); 4-methyl-2-pentanone (141); *o*-fluorotoluene (181); *m*-fluorotoluene (182); *p*-fluorotoluene (182); pyridine (243); and thiophene (248). The molecular formula for oleic acid (p. 151) is also incorrect.

The difficulties in producing a book of this type are considerable, but this compilation is so useful that it is to be hoped that a further twenty years will not be allowed to elapse before the appearance of the third edition.

CRYSTALLIZATION OF HIGH POLYMERS

Some Aspects of the Crystallization of High Polymers

By G. Schuur. (Communication No. 276.) Pp. 82. (Delft: Rubber-Stichting, 1955.) 5 Dutch florins.

THIS is a small monograph dealing with a topic which is of considerable current interest. The mechanism of crystallization of an amorphous solid to a crystalline substance is not easy to elucidate. When a polymer is being dealt with, the difficulties increase immensely, and mobility is restricted in a way that does not occur with simpler systems. The trouble here is to try to deduce something about the mechanism and structure of the crystallites formed during the process by observations on the rate of formation of the nuclei, the rate of growth of the crystallites, and the optical properties of the crystallites. Thus, there is a limited amount of experimental data that can be obtained in such systems, and the interpretation, therefore, is still open to considerable discussion.

The author is a member of the Rubber-Stichting in Delft, and naturally he has a considerable interest in the crystallization phenomena exhibited by rubber. In addition, however, he discusses work done on polyamides and superesters, which are equally relevant to this topic.

The book is divided into a number of chapters which introduce the subject to anyone who is not particularly familiar with it. First there are general remarks about crystallization and the problem of liquid crystals. Next is a factual description of what has been observed about spherulitic formation in solid high polymers, and then follow three chapters on the more controversial aspects of methods of crystallization, the rate of crystallization, and phenomena of melting in high polymers.

The book is lavishly illustrated with extremely good photographs of typical spherulites and their behaviour in a number of systems, which convey in a much better form than any tabular data the qualitative nature of these phenomena. The book will provide much stimulus to those engaged in similar work and should also be an extremely useful guide to those who want to know in a general sort of way what is happening in this field of polymer chemistry.

H. W. MELVILLE

MICROSCOPY OF CERAMICS AND CEMENTS

Microscopy of Ceramics and Cements, including Glasses, Slags, and Foundry Sands

By Herbert Insley and Prof. Van Derck Fréchette. Pp. xii+286. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1955.) 7.50 dollars.

THE use of the polarizing microscope for the study of ceramics and cements has developed considerably in recent years, and a book such as this is welcome. For each group of ceramics, and for refractories and cements, the authors give brief accounts of the raw materials employed and of the behaviour of ceramic materials during firing operations and of cement during hydration. There are short introductory chapters on the microscope and on optical mineralogy, but the authors very rightly refer their readers to standard text-books for further details and also for tabulated and classified data of the optical characters of the minerals and artificial crystalline materials concerned. The characters of the minerals used as raw materials are, however, given in a separate chapter and their thermal behaviour is outlined. Obvious characters by which the materials produced in firing processes may be recognized are described as the occasion arises. The photomicrographs illustrating these descriptions are excellent.

There are two chapters on the preparation of materials for the microscopic examination and on special techniques and, apart from these, there are separate descriptions of methods used for especially difficult materials such as cement clinker, hydrated cements and porcelain enamels on metal. A very high standard of section-cutting must be attained, sections of cement clinker being worked to less than half the thickness of 30μ used for rock sections. Methods of impregnating friable materials and the use of synthetic thermoplastic cements in place of the old-established Canada balsam are described in detail. For the study of some materials too dense to give good results with transmitted light, polished thin sections are prepared and are viewed by reflected or oblique illumination. These are particularly useful for cement clinker, aluminous cements and basic refractories. Delicate etching with very dilute reagents enables the different components to be recognized.

The chapter on glass describes crystalline solids likely to be encountered as 'stones' in the glass. These may be derived from the batch itself, from the refractories in the walls of the pot, or by devitrification. A binocular microscope with oblique illumination can advantageously be used in this work on glasses, and another device, used in the examination of porcelain enamels on metal surfaces, illuminates the specimen through one eyepiece of a binocular, the observer looking through the other.

A criticism may be made that the authors have attempted too much in a small compass; but they have succeeded in giving an up-to-date summary, for each branch of ceramics and cements, and have supplemented every chapter with a fairly full list of references to modern literature on the subject which will direct workers in Britain to most of the recent American work in these fields.

W. CAMPBELL SMITH

Lehrbuch der anorganischen Chemie

Begründet von A. F. Holleman. (34–36, wesentlich umgearbeiterte und erweiterte Auflage.) Bearbeitet von Prof. Egon Wiberg. Pp. xxviii+661. (Berlin: Walter de Gruyter and Company, 1955.) 28 D. marks.

TRANSLATIONS of the late Prof. A. F. Holleman's books on inorganic and organic chemistry have instructed generations of students. They were characterized by clarity and a wise selection of fundamental material. Although as Prof. Egon Wiberg says, his revision bears little relation to the original "Holleman", it preserves the good points of its ancestor.

The text is thoroughly modern, the electronic theory of valency being amply used in it, and the old formulations of inorganic compounds have been replaced by present-day ones. Physico-chemical principles, such as the phase rule and the theory of equilibrium, are freely used. The newer aspects of the subject come at the right places in the text, and difficult topics are dealt with in stages. The theoretical parts of the book are modern and correct. The treatment of the individual elements and compounds is concise yet thorough, and includes more advanced topics of considerable interest, such as the structure of the silicates, the metal carbonyls and the hydrides of boron. The rarer elements find a satisfactory place, and there are brief but good descriptions of industrial processes. There are many tables of physical properties and an excellent index, so that the book is very convenient for reference.

The text is divided into short sections with clear headings, which will facilitate study, and the treatment of each element follows a regular order of occurrence, preparation, physical properties, chemical properties and uses. The nomenclature is based on Stock's scheme, which is becoming more used in all quarters. The illustrations are mostly curves, diagrams of structure and technical apparatus, ordinary preparative laboratory apparatus, even of a specialized type, not finding a place. This book is clear, systematic, sufficiently detailed, and highly informative. It can be warmly recommended.

British Wild Flowers

By Dr. John Hutchinson. Vol. 1: Pp. 492. Vol. 2: Pp. 493–947. (Pelican Books Nos. A.330 and 331.) (Harmondsworth, Mddx.: Penguin Books, Ltd., 1955.) 5s. each volume.

DURING the past few years Dr. John Hutchinson has been occupied in a revision of Bentham and Hooker's monumental "Genera Plantarum", but this enormous task has not prevented him from writing a number of volumes dealing popularly with the British flora. His first three works in the Pelican series were written expressly for those with no knowledge of botany but who wanted to learn the names of the wild plants of the countryside. Undoubtedly these convenient manuals provided a simple and easy introduction to the study of our native plants. They had no systematic arrangement, though plants belonging to the same family were kept together. The latest volumes, which include the contents of the three earlier books with some additional species, correct this unsatisfactory situation, and the sequence of the species described and figured follows the author's system of classification.

The work certainly gives a good general survey of the British flora, though the inclusion of so many adventive species is perhaps unfortunate as there are significant omissions among the native plants and some indigenous genera get rather scant treatment. This is certainly so in the case of aquatic plants. The genus *Callitriche* is entirely omitted, and other groups are poorly represented. Under *Utricularia* it would have been better to refer to the work of Lloyd, who showed convincingly that the bladders were not the static organs they were supposed to be, but ingenious traps which could be set at tension ready to be sprung by contact on sensitive hairs.

The two volumes, in conjunction with C. E. Hubbard's "Grasses" in the same series, can be recommended to amateur field-naturalists needing an authoritative and inexpensive guide to wild flowers in Britain.

Further Outlook

By F. H. Ludlam and R. S. Scorer. Pp. 174+13 plates. (London: Allan Wingate (Publishers), Ltd., 1954.) 15s. net.

IT is the avowed aim of the authors of this interesting and unusual book "not to write a text on the science of meteorology . . . but rather to explain a philosophy of the science of weather study which will enable us to understand its probable future achievements". The result of this laudable purpose is that the essence of the contents is likely to be fully savoured only by the meteorologist, who will be delighted by the novel treatment of certain parts of his subject but occasionally surprised by quite reckless pronouncements. Surely few forecasters would agree with the authors that the geostrophic wind equation is "'the only theoretical result which is constantly put to practical use", or that "no great forecaster has ever written a tract that has found a place amongst the teaching texts of meteorology".

The authors are distinguished for their work in cloud physics and on mountain waves, respectively, and the chapters headed "Exploiting the Atmosphere" and "Weather Control" are those most likely to interest the general reader. The first of these deals with the development of thermals and wave-clouds and with the techniques of soaring flight; there is an intriguing analysis of the dynamic soaring of the albatross. The other is concerned with ways in which weather may be artificially modified, in particular with the physical processes involved in cloud seeding and with the difficulties of assessing whether or not rain-making experiments are effective. The book is illustrated by very fine cloud photographs.

JAMES PATON

Dancers of God

By Nöel Ballif. (Translated from the French by James Cameron.) Pp. 213+32 plates. (London: Sidgwick and Jackson, Ltd., 1955.) 15s. net.

THE author, M. Nöel Ballif, in company with a team of anthropologists and cinema technicians, and with the backing of the Musée de l'Homme, organized an expedition into the forest country of the French Congo to study the pygmies of the region and to make film and sound recordings of their way of life. The book is essentially a travelogue, delightfully written and well translated, and with an interesting account of the daily life of the pygmies with whom they were lucky enough to make friendly contact.

This is in no sense a serious anthropological work, but the description is useful in the same way as are the descriptions of remote peoples by the early voyagers; they give the layman a more vivid picture than a whole book of expert knowledge. An account of hunting with nets and spears is excellent. The book ends with a brief chapter—one might almost call it an appendix—summarizing in five pages the physical anthropology of African pygmy peoples, by Raoul Hartweg, and a list of the anthropological results of the expedition. The book serves to whet our appetite for the more serious and scientific work which will no doubt follow in due course.

Atom Harvest

By Leonard Bertin. Pp. 253+23 photographs. (London: Martin Secker and Warburg, Ltd., 1955.) 20*s.* net.

THIS is a remarkably fine account of a complicated field in which the reader is not asked to worry over-much about scientific or engineering detail at any stage, but nevertheless acquires an accurate broad understanding of the principles involved. Mr. L. Bertin is to be congratulated on accomplishing very adequately on the British side what Mr. Gordon Dean achieved in respect of efforts in the nuclear field in the United States. He considers at some length the history of the thorny questions of collaboration between the two countries, and many readers will be grateful for his forthright way of tackling the subject.

To the general reader interested in a field of paramount importance to the future of the United Kingdom and the Commonwealth, this is a book which can be highly commended. Even the specialist must find within its pages much to interest him, since few can be familiar with all the many facets of the vast programme set forth in it.

In one respect the reviewer found the book fell short of expectation. More consideration should have been given to the present trends in tracer research, and its rich promise for the future of scientific effort in Britain might have been more thoroughly examined. This need not have meant a longer book as the space could have been saved elsewhere without appreciable loss to the reader; for example, the profusion of discussions set forth could have been pruned severely. S. C. CURRAN

Metals Reference Book

By Dr. Colin J. Smithells. Second edition. Vol. 1: Pp. xvi+532+17. Vol. 2: Pp. xv+533–967+17. (London: Butterworths Scientific Publications; New York: Interscience Publishers, Inc., 1955.) £8 8*s.* net the set.

NO one can deny the usefulness of this book, nor the attractiveness of the volumes, although the cost is almost prohibitive for the individual. The aim has been to supply a collection of data relating to metallurgy and metal physics, and to a large extent this has been done in tabular or diagrammatic form.

The scope is wide, in fact so wide in some respects that it encourages an impression that there are omissions. A large part of the subject-matter is fundamental data, such as mathematical formulæ, conversion factors, constants, thermo-chemical data, atomic characteristics, equilibrium diagrams, on crystallography and a considerable range of important physical properties, together with sections on metallography and mechanical properties. On the practical side, the topics include: fuels and refractories, foundry details, lubricants, corrosion, electroplating, and welding. It is the catholic nature of the selection on these aspects that prompts the feeling that comparable subjects have been omitted.

The second edition has involved considerable revision of data, the rewriting of some sections, the addition of more material, and a more elaborate bibliography; resulting in its presentation in two volumes. A commendable point in this connexion is that both volumes contain the index. In all, this can be regarded as an essential reference book for metallurgists and others working with metals.

A. R. BAILEY

A History of the Classification of the Phylum Brachiopoda

By Helen Marguerite Muir-Wood. Pp. vii+124. (London: British Museum (Natural History), 1955.) 20*s.*

THE Brachiopoda are an interesting group with a long fossil history, but their position in relation to other groups is not satisfactorily determined. In the past they have been associated with a number of the major phyla of the invertebrates. Perhaps the smaller group with which they have been linked most frequently is the Bryozoa, but the consensus of opinion now is to regard these as two separate phyla; indeed, some authorities suggest that the Brachiopoda should be subdivided into two phyla, but in this present work Dr. H. M. Wood prefers to regard the Inarticulata and the Articulata as classes. She has gone into the history of all these changes, starting with the first illustration of a member of the group by Conrad Gesner in 1565 but paying particular attention to them since 1785, the crucial date from the point of view of nomenclature.

This useful work is not intended as a definitive classification, but it is a fully documented presentation of the past and present position with regard to their classification. Subsequent workers will be grateful to Dr. Wood for this essential clearance that will enable detailed revision to be started so much more easily. In this, the relevant bibliography, carefully checked, and the full index will be most useful.

British Trade Unionism

Five Studies by P.E.P. New and revised edition. Pp. xi+199. (London: P.E.P. (Political and Economic Planning), 1955.) 16*s.*

THIS new and revised edition appears in a new format, with five studies only, instead of the previous six. Though the framework has been retained and many passages are virtually unchanged, much of the book has been rewritten, and the first study, in particular, with its statistical analysis of the number, size and type of unions in Britain, has been brought up to date. While the book remains a most useful factual handbook, by omitting the sixth study, that of the implications for the trade unions of the changes in post-war Britain, it appears to have lost much of the value which the earlier edition possessed as a stimulus to the fresh thinking about the functions and organization of the trade unions under conditions of full employment. Such issues as the 'closed shop', the unofficial strike, the problems presented by the nationalized industries and the appropriateness of trade-union organization to present-day conditions and their implications, are not brought out in this new edition, which lacks accordingly much of the challenge which the former edition offered.

ROCKET EXPLORATION OF THE UPPER ATMOSPHERE

By Dr. F. E. JONES
Royal Aircraft Establishment, Farnborough

AND

Prof. H. S. W. MASSEY, F.R.S.
University College, London

AT a meeting of the Gassiot Committee of the Royal Society (of which one of us (H. S. W. M.) is chairman and the other a member) held on October 20, 1953, the possible British participation in a programme of observation of conditions in the upper atmosphere by means of rockets was considered. It was concluded that a British programme would be worth while and possible if support were forthcoming from the Ministry of Supply, and in particular the Royal Aircraft Establishment, which would be required to design a suitable rocket and provide firing facilities.

Details of a possible collaboration between the Gassiot Committee and the Royal Aircraft Establishment were discussed at Farnborough on January 29, 1954, and, as a result, the agreement in principle of the then Minister of Supply, Mr. Duncan Sandys, was obtained in March 1954. The final recommendations of the Gassiot Committee were endorsed by the Council of the Royal Society in November 1954, and the participation of the Royal Aircraft Establishment in the experiment was put on a firm footing as a result of the exchange of letters between Sir David Brunt, secretary of the Royal Society, and Sir Owen Wansbrough-Jones, chief scientist, Ministry of Supply, during the period November 1954–February 1955. Treasury support to the extent of £100,000 spread over four years was agreed on June 29, 1955, to be divided into £50,000 to cover the design and provision of rocket vehicles by the Royal Aircraft Establishment and £50,000 to be made available to the Gassiot Committee, through the normal Air Ministry channel, to cover the cost of the experimental investigations. Some details of the arrangements were released to the popular press in August last. The present article gives details of the rocket, now known as the 'Gassiot vehicle', and an outline of the initial experiments to be undertaken with it.

In designing the rocket vehicle, the considerations of ease of manufacture, preparation for firing and total cost per flight have been kept very much in mind. From these considerations the design has been centred on a single-stage uncontrolled rocket propelled by a solid-fuel motor, the problem being to achieve great height at reasonable cost. The advantages of releasing the rocket from a balloon, in a similar manner to the American 'Rockoon', have been considered; but it was concluded that by suitable choice of motor burning-time the loss in performance due to aerodynamic drag in the lower atmosphere could be considerably reduced and the additional expense and complication of a balloon launch avoided. In addition, a delay of half an hour or more required for a balloon to reach altitude before firing the rocket would not be acceptable in some experiments.

Much in the way of final performance of the rocket depends on the burning-time of the motor. A fast-burning motor produces high velocities in the lower atmosphere with resultant excessive drag. A slow-burning motor usually means a reduction of specific impulse and, because of the lower accelerations involved, the dispersion problems in an uncontrolled vehicle increase. The optimum burning-time seems to lie in the region of 30 sec. and this is the value chosen for the Gassiot vehicle.

The outline design of the rocket is shown in Fig. 1. The fins are of an existing design and later versions will not have swept trailing edges. The nose cone, which will house the instrumentation, is made of 14-gauge steel with provision for jettisoning the forward portion at the 10-in. diameter region. Just aft of the nose cone is a portion of the body which houses the telemetry, ancillary instrumentation and power supplies. The total weight of the rocket at launch will be just over 2,500 lb., by far the greater portion of which is fuel. The total payload made up of instrumentation and telemetry equipment for a height of 550,000 ft. is 150 lb.

The launcher is illustrated in Fig. 2. The structure consists of a vertical 'boom'—the launch way—supported at approximately its mid-point in a gymbal system, the gymbal framework forming the apex of a large tripod. The launching angle is variable through ±10° in azimuth and from 75° to 95° in

elevation, thus allowing for a variety of wind conditions. The launcher is 81 ft. high, stands on a 72-ft. diameter base and weighs about 35 tons. It is designed to fire either the British Gassiot vehicle described above or the American 'Aerobee' rocket without change.

Figs. 3, 4, 5 and 6 give the main performance characteristics of the rocket. Fig. 3 gives the velocity–time and height–time performance curves; Fig. 4 the height–range curves for various launch trajectories; Fig. 5 the acceleration–time curve for vertical flight and Fig. 6 the maximum height reached as a function of payload. From the curves it is seen that a height of about 550,000 ft. will be reached with a payload of 150 lb. Later versions of the rocket should reach about 700,000 ft.

The vehicle is uncontrolled, and consequently dispersion is largely an unknown factor. For this reason arrangements are being made with the Australian Government for the initial firings to take place at the Woomera Range in Australia. A launcher is due to be shipped there this spring to enable experimental firings to be done in the September–October period of 1956. It is hoped to undertake firings both at Woomera and in the United Kingdom during the International Geophysical Year (1957–58). If these tests show that the dispersion is excessive, a boost to increase the velocity at launch or a small rocket motor to produce rolling for the first 5 sec. of flight will be introduced.

The actual upper-atmosphere experiments are being designed and the flight instrumentation made by a number of university departments and by the Royal Aircraft Establishment under the general guidance of the Gassiot Committee. University College, London (Prof. H. S. W. Massey, Dr. R. L. F. Boyd), are to measure wind, temperature and pressure by the grenade method. In this experiment observations are made at a number of points on the ground of a series of grenades fired from the rocket at approximately equal intervals along the trajectory. In addition, University College, London, also plans to fly a mass spectrometer for ion sampling. The University of Birmingham (Prof. J. Sayers) is to make a study of ionospheric conductivity and relative concentration of electrons to negative ions by a sampling ionization chamber fitted with a pulse method of distinguishing between ions and electrons. The Queen's University of Belfast (Prof. D. R. Bates) is to make measurements with photoelectric photometers and filters to study the relative intensities of certain spectral lines of molecular oxygen and the altitude of the night airglow in the regions of the oxygen green line and the Meinel OH bands; it is also planned to study the emissions resulting from the

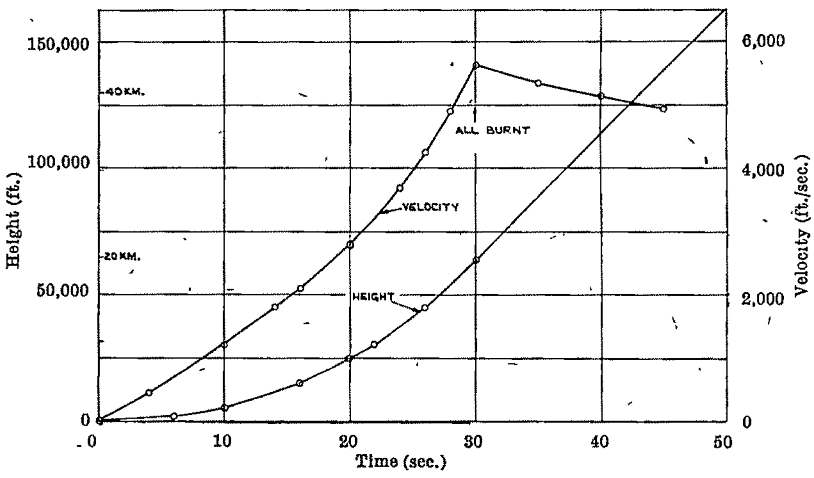

Fig. 3. Velocity–time and height–time performance curves

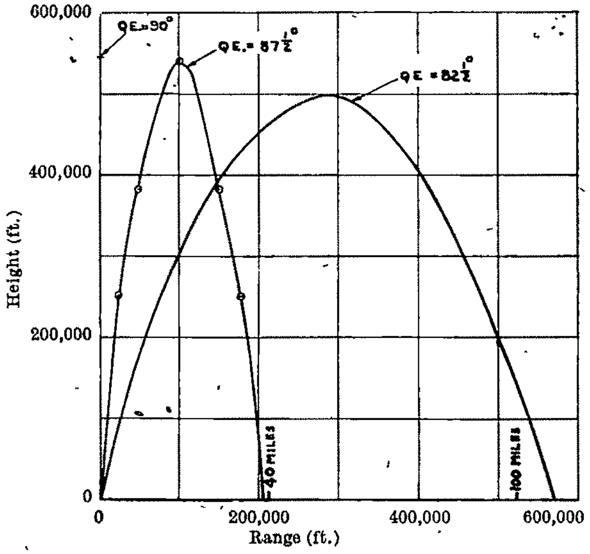

Fig. 4. Height–range curves

release of sodium and potassium vapour at high altitudes. University College, Swansea (Dr. W. J. G. Beynon), is working on two methods—continuous-wave Doppler and the pulse method—of measuring electron densities in the ionosphere and is correlating these simultaneously with measurements made from the ground. The Royal Aircraft Establishment is planning to measure skin temperature and altitude of the rocket and is also studying the design of a sun-seeker for carriage in the rocket. The sun-seeker would be used for measurements of solar radiations and for obtaining ultra-violet pictures of the sun at high altitude.

The rate of progress in the design and construction of the various instruments is such that there is every likelihood of a number of measurements being made during the International Geophysical Year.

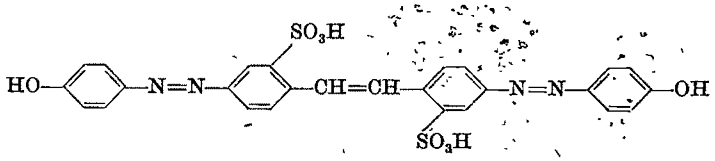
RECENT ADVANCES IN THE CHEMISTRY OF COLOURING MATTERS

ON February 2, the Chemical Society held a symposium in London on "Recent Advances in the Chemistry of Colouring Matters". This was organized by Prof. E. A. Braude (Imperial College of Science and Technology, London) and held in the Royal Institution. Prof. W. Wardlaw, president of the Society, opened the proceedings. He reminded those present that this year marks the centenary of the discovery by W. H. Perkin of the very first synthetic dyestuff, mauve. He quoted Sir Robert Robinson to the effect that the discovery itself had little scientific importance : what was important was the fact that Perkin embarked upon its manufacture, which he achieved, and he thus became founder of the coal-tar dyestuffs industry.

Dr. R. P. Linstead (vice-president of the Society) took the chair for the afternoon session. The following papers were read : "Steric Effects in Azo and Indigoid Dyes", by W. R. Brode (U.S. Bureau of Standards, Washington) ; "*Cis-trans* Isomerism in Azo-dyestuffs", by R. H. Peters and E. Atherton (Manchester College of Technology) ; and "Synthesis of Azaporphins and Related Macrocycles", by J. A. Elvidge (Imperial College).

Dr. Brode gave evidence that there is no selective adsorption of certain optically active dyes on asymmetric fibres such as wool, silk or cotton. However, with simpler compounds, for example, *m*-nitromandelic acid, there is selective adsorption of one of the optical forms. It appears that the resonance centre of the dye molecule is more important for adsorption than an asymmetric centre, particularly in the absence of conjugative coupling between the two.

Dr. Brode then described *cis-trans*-isomerization effects in dyestuffs. Changes in light absorption on irradiation can be correlated with *trans* to *cis* isomerization about azo-links. *Ortho* substituents



(I) Chrysophenine *G*

inhibit this phototropism, as also can hydroxylic solvents by a hydrogen-bonding effect. Studies have also been made on bis-azo dyes in order to determine the extent of resonance interaction between the two chromophoric centres. Where the chromophoric systems are insulated sterically or by methylene groups, the property of direct dyeing of cotton is lost. For dyes of this class which show phototropism, only *cis*- and *trans*-modifications are apparent in solution and the spectral curves show isosbestic points. When there is conjugative coupling between the chromophoric systems, an isosbestic line is found, because of the possible existence of an intermediate *cis-trans*-chromophoric system.

The bis-azo stilbene dye, chrysophenine *G* (I), shows phototropism in aqueous solution, but this is restricted to intensity, rather than colour, changes. The two azo-benzenoid chromophores are electronically connected and the dye is substantive, even though the sulphonic acid groups *ortho* to the stilbene ethylenic linkage prevent coplanarity in the molecule.

The absence of phototropism in indigo can be attributed to strong hydrogen-bonding. There is none in NN′-diacetylindigo or -dimethylindigo, and these derivatives show phototropic inversion, as also does thioindigo in neutral solution.

Lastly, Dr. Brode described association effects. Whereas mixtures of brilliant yellow and guinea green show summation spectra, brilliant yellow and genacryl pink do not because of association. Optical bleaching agents, which in effect are colourless dyes, may also associate with dyestuffs and thereby affect their colour. The prevention of association by heat, powerful solvents and dispersoids has been studied, particularly for the system chrysophenine *G*–sky blue *FF*. Here, irradiation also causes a change toward the summation spectrum, apparently because of inversion of chrysophenine *G* into its *cis*-form, which does not associate with sky blue *FF*. The association of dyes appears to be an adhesion of strongly charged resonance structures, probably closely akin to the adhesion to fibres, which are isoelectric charged materials. In each case, the distortion of the resonance system, consequent upon the adsorption, could account for the slight change in absorption spectrum.

The second paper, read by Prof. Peters, provided evidence that *trans* to *cis* isomerization in azo-dyestuffs is responsible for the fading or change in colour of dyed textiles in light: the *cis*-form would be removed in subsequent washing of the textile, as it is not firmly adsorbed in the fibre. In fading experiments, the rates of destruction of a series of benzene-azo-α-naphthylamines, substituted in the benzene nucleus, were determined. Rate constants for the *cis* to *trans* change of these compounds in the dark were also measured, and the activation energies found to be around 20 Cal. This supports the assumption that the phototropy is the result of inversion of the azodye to the *cis*-form in light.

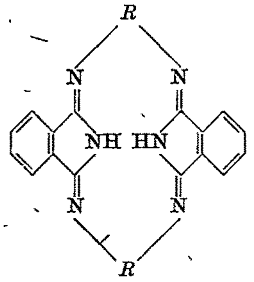
The phototropy of the direct cotton dye, chrysophenine *G*, was also studied. There are three possible centres about which *cis-trans* isomerism can occur, but since the spectra show isosbestic points, only two forms are present in the irradiated solutions. Rates of conversion and activation energies indicate that the transformation involves azo links and not the ethylenic group.

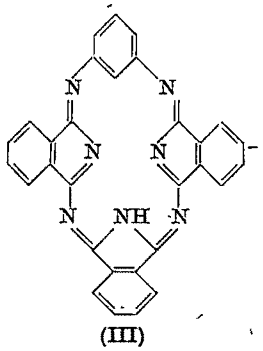
The absorption spectrum of the *cis*-form was determined from the spectrum of a mixture of the two forms by a method involving the dependence of the optical density on wave-length. Also the *trans*-form could be removed from a mixture by chromatography on cellulose powder.

The *cis*-form showed very little substantivity for cellulose fibre. This suggested that the dye needs to be linear and planar, and the latter condition does not hold in the *cis*-form. No *cis*-form was detected in the spectrum of dyed cellulose sheet.

Similar considerations apply to the interaction of chrysophenine *G* with chlorazol sky blue *FF* (Col. Index, 518), which has a linear structure. The spectrum of a solution of a mixture of these dyes departs from additivity. Irradiation causes a change towards the summation spectrum, because doubtless the non-linear and non-planar *cis*-form of chrysophenine *G* is unable to adlineate itself alongside the linear and planar molecule of sky blue. In the dark, the system recovers its original absorption spectrum at a rate equal to the *cis* to *trans* conversion for chrysophenine *G*.

The third paper, on the synthesis of azaporphins and related macrocycles, was given by Dr. Elvidge. The established methods for synthesis of the phthalocyanines have, of course, been extended to the preparation of symmetrically substituted tetrazaporphins, but they are unsuitable for the preparation of unsymmetrical derivatives. In 1950, Prof. R. P. Linstead had suggested the use of imidines as intermediates. The imidines (nitrogen analogues of cyclic anhydrides) are readily obtained from vicinal dinitriles and ammonia. One of their many reactions is ready condensation with amines, and this led to unexpectedly easy syntheses, from phthalic imidine and cyclic-1 : 3-diamines, of cross-conjugated macrocycles (II) with 16-, 20- and 24-atom rings. These compounds are mainly yellow. That with *R* = 2 : 6-pyridyl has a central arrangement akin to that in the azaporphins and, like them, complexes bivalent tetra-co-ordinate metals.





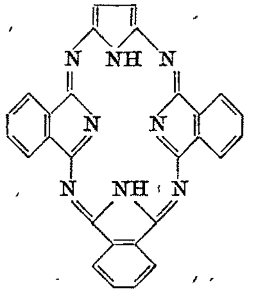
(III)

(II; *R* =  etc.)

Resulting from an attempt to separate the several stages which must be involved in the formation of the macrocycles (II), the red, cross-conjugated macrocycle (III) was obtained. This has, in a sense, three-quarters of the chromophore of phthalocyanine.

Dr. Elvidge then outlined working principles which seem to apply to the *self*-condensation of imidines. A mixture of three molecular proportions of an unsaturated imidine with one of a saturated imidine can give rise directly, by elimination of four molecules of ammonia, to a tetrazaporphin ; other proportions, and self-condensations, can yield tetrazaporphins only through supplementary oxidation-reduction processes and are in general unfavourable.

Interaction of the imidines derived from phthalonitrile and succinonitrile affords tribenzotetrazaporphin (IV), the first unsymmetrically substituted tetrazaporphin to be isolated and fully characterized. This and homologues are of interest for their light absorptions and behaviour on hydrogenation. The tribenzotetrazaporphins can yield comparatively stable dihydro derivatives, like the porphyrins, in contrast to the symmetrically substituted azaporphins, the reduction of which has so far resulted in the isolation only of tetrahydro derivatives.



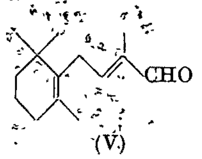
(IV)

By the condensation of a mixture of appropriately substituted imidines, an alkyl substituted tetrazaporphin had been prepared which is at the tetrahydro level : this can only pass to the normal tetrazaporphin 'aromatic' level by the migration of alkyl groups, so that it is ordinarily stable and easy to handle. It was hoped through this and related macrocycles to determine the relative positions of the hydrogen atoms in the tetrahydroazaporphins and thence in those hydroporphyrins which are at the bacteriochlorophyll level.

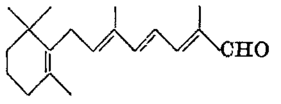
The afternoon session of the symposium concluded by an open discussion, which lasted some forty-five minutes. One participant, Dr. J. S. Holt (Courtauld Institute of Biochemistry), presented strong evidence for intermolecular, as opposed to intramolecular, hydrogen bonding in indigo.

At 7.30 p.m. Sir Alexander Todd took the chair for the evening session. The papers read were : "Synthetic Carotenoids", by O. Isler, H. Lindlar, M. Montavon, R. Rüegg, G. Saucy and P. Zeller (F. Hoffmann-La Roche and Co., Ltd., Basle), and "Modern Theories of Colour", by M. J. S. Dewar (Queen Mary College, London).

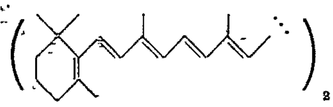
Dr. Isler indicated some carotenoids that his group has synthesized : β-carotene, 7 : 7′-dihydro-β-carotene, lycopene, zeaxanthin, cryptoxanthin, physalien and bixin, and the building principles employed in the manufacturing processes.



(V)



(VI)



(VII)

β-Carotene is being produced—in ton quantities—starting from β-ionone. This is converted to the C_{14} aldehyde (V) by glycidic ester synthesis and treatment with alkali. The carbon chain is then lengthened by the reaction of the acetal of (V) with ethyl vinyl ether. Treatment of the product with acetic acid gives the crystalline C_{16} aldehyde, which is then converted to the C_{19} aldehyde (VI) by similar steps involving ethyl propenyl ether. Two molecules of C_{19} aldehyde are condensed with acetylene *via* its Grignard or lithium derivative, and the resulting C_{40} diol is treated with alcoholic hydrogen chloride to cause allylic rearrangement and dehydration. The 15 : 15′-dehydro-β-carotene (VII) crystallizes out well and is easily separated from all by-products. Catalytic hydrogenation with Lindlar's catalyst and isomerization at 30° (both with the crystalline carotenoids in suspension in petroleum) complete the synthesis of β-carotene.

From the C_{40} diol with lithium aluminium hydride (an application of the Nayler–Whiting reaction) crystalline 7 : 7′-dihydro-β-carotene is obtained in more than 80 per cent yield.

Dr. Isler then outlined syntheses of zeaxanthin and physalien, which can be achieved on similar lines to that of β-carotene Several alternative routes to β-carotene were also described.

In a synthesis of lycopene, use was made of the Wittig reaction. Geranyl bromide, from linalool, is added to triphenylphosphine, and the phosphonium bromide converted with phenyl lithium to geranylidenetriphenylphosphine, which is condensed with crocetindialdehyde to yield crystalline lycopene. The crocetindialdehyde is obtained by starting from acetylene and α-methacraldehyde, which yield a C_{10} dialdehyde. Chains are added at each end with ethyl vinyl ether and then ethyl propenyl ether, via the aldehyde acetals, and the final step is semi-hydrogenation of the central triple bond of the C_{20} dialdehyde to yield crocetindialdehyde.

Dr. Isler concluded with a tribute to his team in Basle, and he quoted Sir Ian Heilbron to the effect that with the overcoming of the major synthetical problems of carotenoid chemistry, it should now be the turn of the biochemist to help uncover the role of the carotenoids in the living cell.

Prof. Dewar began by illustrating how ideas of quantum theory provide a qualitative understanding of the relation between colour and constitution. A molecule such as that of hydrol blue (VIII), for which two classical structures of identical energy can be written, will be a hybrid or superposition of these structures. Its wave-function, ψ, will be a combination of those (φ_1 and φ_2) of the individual structures,

(VIII)

and two values can be derived, one ($\psi_1 = \varphi_1 + \varphi_2$) representing a ground-state of lower energy than either interacting structure alone, and a second ($\psi_2 = \varphi_1 - \varphi_2$) of higher energy. The molecule will, of course, normally exist in the ground-state, but may be excited to the higher one by absorption of light of appropriate frequency. Where two possible classical structures for a molecule differ in energy, the energy difference between ground- and excited-states becomes greater, and such a dye will absorb at a shorter wave-length than otherwise.

These ideas have been successfully extended to the cyanine dyes, which can be represented as $\overset{+}{A}.\text{—}B \longleftrightarrow A\text{—}.\overset{+}{B}$. The more chemically similar the end groups *A* and *B* are, the less will the position of the absorption band deviate from the mean position of those for the two symmetrical dyes *A*—*A* and *B*—*B*. The Brooker deviation series provides a striking confirmation.

Prof. Dewar also mentioned how these ideas explain the solvent effect on the position of absorption bands. There is nevertheless a flaw in the treatment, because interaction of pairs of classical structures can only take place through a series of intermediate structures. Analysis of the resonance between the complete set of structures is mathematically very difficult; but calculations have been done and they justify the conclusions of the simpler treatment. Easier to apply is the molecular orbital method, which has met with considerable success in accounting quantitatively rather than qualitatively for the colour of cyanine and other cationic or anionic dyes. Prof. Dewar elaborated the 'free electron molecular orbital' approach, pointed out its limitations and successes, and went on to describe the 'perturbation molecular orbital' method. This is capable of accounting quantitatively for the light absorptions of aromatic hydrocarbons, as well as of cyanines, and related basic, acidic and azo dyes.

The relation between colour and constitution for the vat dyes, however, is much more difficult to interpret and possibly requires the development of more precise theoretical methods.

The papers of the symposium, with bibliographies, will be published by the Chemical Society, London, in *Special Publication* No. 4; this will include an account of the discussions, which were tape-recorded.

J. A. Elvidge

OBITUARIES

Dr. H. E. Woodman

Herbert Ernest Woodman died on February 13 at the age of sixty-six. He had been on the staff of the School of Agriculture at Cambridge for thirty-six years and was well known to generations of undergraduates. He was a leading authority on animal nutrition in Great Britain.

After graduating at the University of Leeds, he spent another year working under Prof. J. B. Cohen in the Chemistry Department there. He was then awarded an 1851 Exhibition and spent two years at Göttingen under Prof. O. Wallach, working on the terpenes, and he received the degree of Ph.D. in 1914. Later that year he joined the Animal Nutrition Research Institute, then at Leeds. He was awarded the D.Sc. degree of Leeds in 1921. Woodman at first worked with C. Crowther on the nitrogen metabolism of the dairy cow, and later with H. W. Dudley on the origin of the proteins in milk. This work established the identity of euglobulin and pseudoglobulin, whether from serum or colostrum, but showed that lactalbumin and serum albumin were two distinct proteins. When the Institute was transferred to Cambridge in 1920, Woodman went with it. He was appointed University demonstrator in October 1926, University lecturer in October 1930, and reader in animal nutrition in 1950.

In the early 'twenties, ensilage was rapidly gaining adherents in Britain, but there was a complete lack of knowledge of the magnitude and nature of the chemical changes occurring in the silo. Woodman, therefore, in conjunction with A. Amos, carried out a detailed and systematic investigation of the conditions responsible for the production of different types of silage and devised methods of analysis that are still in common use. The results were published in the form of a bulletin ("Ensilage", Bull. 37, Ministry of Agriculture), which was revised periodically by Woodman, and proved a great boon to the practical farmer as well as to the teacher.

In 1925, Woodman, with the encouragement of Prof. T. B. Wood, gathered together a team of young scientists to secure information concerning the nutritive value of pastures. This work continued over a period of twelve years and became a classic. It involved the determination of yield of dry matter, chemical composition, digestibility for sheep and pigs and the starch equivalent and protein equivalent per acre when the pasture was subjected to varying systems of management. A noteworthy finding was that young grass is a protein-rich concentrate, comparable in some respects with linseed cake. Living in Cambridge, with its lawns and playing fields, Woodman was attracted by the idea and possibility of the preservation of young grass for winter feeding by artificial drying. He carried out pioneer work in this field, and the present flourishing crop-drying industry is a tribute to this early work. Afterwards, investigations were made into the effect of management on the nutritive value of other forage crops like lucerne and kale. This information proved of inestimable value during the war years.

Woodman was the author of about 170 scientific papers covering a wide range of subjects. He made a valuable contribution to our knowledge of such diverse subjects as sheep nutrition, the nutritive value of sugar beet by-products and the mechanism of cellulose digestion in the ruminant.

In 1930 Woodman and I published our first joint paper, the forerunner of many more, during a close research partnership that lasted more than twenty-five years. In 1936, the first of a series of eighteen papers on the nutrition of the bacon pig appeared. Great stress was laid in this paper on experimental technique and the importance of designing an experiment so that the results could be analysed statistically. It was shown that an individual-feeding trial could be four times as accurate as a corresponding group-feeding trial. The question of the protein requirements of pigs received early consideration. It was demonstrated that equally good results could be obtained, from the point of view of growth, economy of food conversion and carcass quality, when all-meal rations supplying only 7 per cent of white-fish meal were fed, as with diets much richer in protein. Moreover, it was shown that if the protein-rich concentrate was omitted altogether from the diet after 90 lb. live-weight, it was without the slightest effect on the rate of live-weight gain or on the leanness of the carcass. Considerable economies were therefore possible in the use of white-fish meal, which proved of great importance when supplies were short. The replacement of animal protein by vegetable protein plus minerals was also investigated.

On the death of Prof. T. B. Wood in 1930, Woodman became responsible for the sixth edition of "Rations for Livestock", the best-seller among the *Bulletins* of the Ministry of Agriculture. It became imperative in 1948 that the *Bulletin* should be almost entirely rewritten, and from this date Woodman assumed full responsibility as author. Woodman was also the author of the other bulletins—"Home Grown Feeding Stuffs" and "The Use of Oil Cakes and Extracted Meals"—which have lately been out of print. Finally, mention should be made of his contributions to *Agriculture*, during the War, of "Notes on Feeding Stuffs", which gave the results of research work at Cambridge and elsewhere, and were greatly appreciated by farmers and others.

No account of the work of Woodman would be complete without reference to his ability as a teacher. His great joy in life was in lecturing to the degree class at Cambridge. He was a born teacher and took infinite pains in the presentation of the material and had the gift of making a difficult subject seem easy.

He leaves a widow, a son and daughter, and a grandson.

R. E. EVANS

Dr. H. Wormald

HARRY WORMALD, who died at his Maidstone home on December 10 last at the age of seventy-six, was distinguished for his pioneer work, over the past forty-five years, on the pathology of fruits and hops, and more particularly for his original researches on the two important groups of diseases, brown rot (*Sclerotinia* spp.) and bacterial canker (*Pseudomonas mors-prunorum* and *Ps. prunicola* Worm.), in both of which fields he became an authority of international repute.

Born a Yorkshireman, he first trained as a schoolteacher and for eight years taught a general curriculum in schools in Bradford and Leeds. It was therefore not until he was thirty years of age, in 1908, that with a Board of Education scholarship he went to London to read botany at the Royal College of Science (Imperial College of Science and Technology) under Prof. J. B. Farmer. Three years later he gained his A.R.C.S. and also the B.Sc. degree of the University of London with honours; and after a further year of research at the Royal College of Science, when he was awarded the diploma of the College, he went in 1911 to Wye College in Kent (University of London) as assistant in the Botany (Mycology) Department under E. S. Salmon. The dominating interest in fungal and bacterial diseases of fruits and hops which Wormald developed at Wye is reflected in the award of the D.Sc. degree in 1919 for his early publications on brown rot, and in his transfer in 1923 to the then young East Malling Research Station as the first head of its Plant Pathology Section. There he worked for twenty-two years under the inspiring directorship of R. G. Hatton, and as the beloved chief and mentor of a long succession of postgraduate students and colleagues. It was at East Malling that Wormald consolidated his early work on the brown rot and crown gall diseases, and initiated the brilliantly original etiological studies on the bacterial canker diseases of the stone fruits.

In 1936 Wormald was appointed assistant director at East Malling, and for ten years, from 1935, he edited the Station's Annual Report. In 1940 he became president of the British Mycological Society and was joint editor of the *Transactions* of that Society during 1931–45. He also served as a member of the Council of the Association of Applied Biologists (1937–39) and as a vice-president (1938–39).

In 1945, in his sixty-sixth year, Wormald finally retired from East Malling, and in the same year joined the staff of the Commonwealth Bureau of Horticulture and Plantation Crops, stationed at East Malling, where for seven years he exercised his linguistic gifts (he could translate fluently from seven languages, including Russian) as an abstractor of world horticultural literature.

In 1952, at the age of seventy-three, Wormald was obliged to retire from the Bureau because of the illness to which three years later he was to succumb, only, however, to continue at home, with the quiet and patient tenacity of purpose which characterized his whole research career, the preparation of new editions of his two principal works, the monograph "The Brown Rot Diseases of Fruit Trees" (Ministry of Agriculture and Fisheries), and the standard text-book on his subject, embracing the impressive corpus of his original research papers, "The Diseases of Fruits and Hops" (Crosby Lockwood and Son, Ltd.). With the devoted and unflagging support of his wife, these immense tasks were brought to a successful conclusion, and within six months of the publication of the new edition of his text-book he died.

R. V. HARRIS

Mr. F. W. K. Gervers

FRANK WALTER KITCHENER GERVERS was born on April 17, 1920. He went to school at Bradfield, where he became an enthusiastic member of the School Natural History Society and published a paper of unusual quality for a schoolboy on the biology of a small stream. When he left school in 1939 he followed a family tradition and joined the Regular Army. He served in the Royal Artillery in North Africa, Italy and India; but his active military career was terminated by ill-health in 1946 and he decided to resume his interest in biology.

Gervers went to the University of Glasgow and during vacations worked in the laboratories at Pitlochry, Aberdeen and Lowestoft, and went to sea on the research vessels. After graduating he worked for a year with Dr. H. D. Slack on the biology of Loch Lomond, studying particularly the white fish or powan found there. In 1953, he joined the fresh-water fisheries staff of the Ministry of Agriculture and Fisheries and carried out a most useful study of the food of coarse fish. He also took a large part in the work on the migration of sea trout and had begun an investigation into racial characteristics of salmon. His death on the last day of October 1955 deprived all who knew him of a much-valued friend and cut short a scientific career of great promise. He left a widow and two small children to whom he was devoted, and we extend our deepest sympathy to them.

F. T. K. Pentelow

[A communication of which he was part-author appears on p. 664 of this issue of *Nature*.]

NEWS and VIEWS

Refractories Technology at Sheffield :
Prof. J. White

The firm of J. and J. Dyson, Ltd., of Stannington, manufacturers of refractory materials, has given £15,000 to the University of Sheffield for the establishment of a chair in refractories technology, which the University has named the Dyson chair of refractories technology, and Dr. James White, reader in ceramics in the University, has been appointed the first holder. After graduating in physical chemistry from the University of Glasgow in 1931, Dr. White did metallurgical research at the Royal Technical College, Glasgow, and later became lecturer in metallurgy there. In 1939 he was awarded the Carnegie Gold Medal of the Iron and Steel Institute. He left the College in 1943 to become head of research of General Refractories, Ltd., and three years later went to the University of Sheffield as senior lecturer in refractory materials, being appointed reader in ceramics in 1952. Dr. White has published a large number of research papers and is a recognized authority on the chemistry of ceramics and refractory materials. The creation of the new chair, which is the first such one to be established in Great Britain, and of a separate department specializing in the subject, should do much to further the advancement of knowledge in a field of great importance to the steel industry of Britain, and especially the industries of the Sheffield district.

Botanical Survey of India :
Dr. G. S. Puri

Dr. G. S. Puri, formerly ecologist at the Forest Research Institute, Dehra Dun, has been appointed regional botanist-in-charge of the northern circle of the Botanical Survey of India. In 1938 he came under the influence of Dr. R. R. Stewart and joined him in the explorations of the Kashmir, Hazara and Murree Hills, and collected extensively. In 1940, at the invitation of Prof. B. Sahni, he joined the Botanical Department of the University of Lucknow and worked on the flora of the Karewa formations of Kashmir, for which he was awarded the Ruchi Ram Sahni Prize for the best research in the University. He has conducted extensive geological and botanical explorations in the Kashmir Himalayas and discovered fossiliferous strata. During 1942–45 he worked on the correlation of oil-bearing strata in the Assam Tertiaries by micro-fossils for the Burmah Oil Co., Ltd., a pioneer work in India. In 1945 he was selected by the Government of India for training abroad in ecology and systematic botany and worked in the University of London under Prof. W. H. Pearsall. He is secretary of the Indian Council of Ecological Research and the Society of Tropical Ecology.

Research at Fort Dunlop, Birmingham :
Mr. E. A. Murphy

Mr. E. A. Murphy, general development manager at the Research Centre, Fort Dunlop, Birmingham, has been appointed director of research in charge of the central research division of the Dunlop organization. Mr. Murphy, who, for his services to the rubber industry, has been awarded the Colwyn Medal by the Institution of the Rubber Industry, joined the Dunlop chemical laboratories during the First World War. One of the activities of the general development division set up under him during the Second World War was the investigation of synthetic rubber manufacture. A pilot plant was then started and this led to the designing of the experimental plant for synthetic rubber production now being erected at the Research Centre, which has enabled Dunlop to take the leading part in the project for the large-scale manufacture of synthetic rubber in Britain by the recently formed International Synthetic Rubber Company.

Government Pressures on the Press

The International Press Institute, Zurich, has published as Survey No. 4 a study on "Government Pressures on the Press", which displays clearly but objectively the gravity of attacks that have been made on the freedom of the Press, even outside the totalitarian States, and the dependence of effective defence against such attacks upon an informed public opinion. The reasons which may lead even a liberal-minded government to desire the Press to exercise some restraint on publication are fairly indicated; it is emphasized that the Press is not above the law and that, although ideally the freedom of the Press should be complete, in practice this has to be qualified, nor can governments be indicted for not tolerating attacks which might endanger their existence. The first part of the study analyses pressures based on the law, the second those of an economic, administrative or purely political nature, and the third part in particular shows that the scientific and technical Press is no more immune from such pressures than the newspapers. The Institute is particularly concerned about the situation in South Africa, and especially because of the public apathy to successive government enactments during the past five years which have made the position of the Press there most precarious. In Australia and in India there are restrictive laws which are potentially dangerous; though they are not likely to be so applied by present or viable governments. The value of the study lies in the assembly of a large amount of factual material in convenient form and in indicating the nature and causes of the present threats to freedom of the Press. By and large, they arise less from the spread of illiberalism than from the growth of government and the domain of official policy in a divided and uneasy world.

National Research Development Corporation of India : Report for 1954–55

The National Research Development Corporation of India was registered on December 31, 1953, its main function being to stimulate the development of patents and inventions arising out of researches conducted in research institutions financed out of public funds and, where feasible in the public interest, of patented inventions from individuals also. The Corporation has an authorized capital of Rs. 1 crore, and the late Sir Shanti Bhatnagar was an original member of its board of seven directors, of whom S. K. Lalbhai is chairman. Its first annual report (pp. 17; from the Corporation, New Delhi), to which are appended the statement of accounts and the objects of the Corporation as set forth in the articles of association, covers the period ended March 31, 1955, a period in which 177 inventions from twenty-four institutions and eight private individuals were reported for development. Trials have been arranged of a process for the manufacture of paper from wattle-wood, and negotiations were in progress for trials of processes for the manufacture of newsprint and cheap printing-paper from bamboo and for the de-ionization of cane-sugar; licences have also been negotiated for ten other processes. Processes for the manufacture of writing and printing paper from bagasse, for the recovery of nickel and fat from spent hydrogenation catalyst of vanaspati (vegetable oil) factories and for myrobalan extract in the myrobing of East Indian tannage of skins and kips have been made available to industry without any conditions regarding payment of royalties, and 62 processes are under critical examination. Normally the Corporation proposes to take 30 per cent of the gross earnings from premiums and royalties and pay 70 per cent to the research institutions.

Technical Education in Britain

In reply to questions in the House of Commons on March 20, the Secretary of State for Scotland said that in central institutions in Scotland there are about five hundred full-time and a thousand part-time teachers of technical subjects, of whom some three hundred full-time and twenty part-time teachers are doing work of approximately university level; and in other institutions of further education there are 650 full-time and 5,100 part-time teachers of technical subjects. Education authority projects in preparation include local technical colleges at Aberdeen, Dundee, Kilmarnock, Clydebank, Inverness, Motherwell and Bathgate, and three at Edinburgh; a schedule of accommodation has been approved for local technical colleges at Ayr and Falkirk, and projects which have been started include a local technical college at Paisley, Lauder Technical College, Dunfermline, Stow College of Printing, Glasgow, and Lees Castle College, Ross and Cromarty. Projects at central technical institutions expected to start in the next two years include internal adaptations and new premises for the School of Navigation at the Royal Technical College, Glasgow, and extensions to Paisley Technical College, to the Pharmacy Department of Heriot-Watt College, Edinburgh, and to Robert Gordon's Technical College, Aberdeen.

Society for Analytical Chemistry

The eighty-second annual general meeting of the Society for Analytical Chemistry was held in London on February 29, when the financial statement and the report of the Council for the past year were submitted and approved. The membership of the Society was reported as 1,842, an increase of 43 since last year. During the year the Society organized six ordinary meetings in London (three of which were organized by the Society's subject groups), and the first joint meeting with the Association of Public Analysts was held in Cardiff; in addition, the Society's Sections and Groups held thirty-seven meetings. A special meeting was held in London on November 29, when Prof. J. Heyrovský, an honorary member of the Society, gave a lecture entitled "The Development of Polarographic Analysis". The following officers and members of Council were elected for the forthcoming year: *President*, K. A. Williams; *Past Presidents serving on the Council*, Lewis Eynon, D. W. Kent-Jones, J. R. Nicholls and George Taylor; *Vice-Presidents*, D. C. Garratt, J. Haslam and H. M. N. H. Irving; *Honorary Treasurer*, J. H. Hamence; *Honorary Secretary*, N. L. Allport; *Honorary Assistant Secretary*, R. E. Stuckey; *Other Members of Council*, S. G. Burgess, R. C. Chirnside, C. H. R. Gentry, W. C. Johnson, D. D. Moir, T. McLachlan, R. F. Milton, Miss Mamie Olliver, F. C. J. Poulton, S. A. Price, A. A. Smales and A. F. Williams; *Ex-officio Members*, J. R. Walmsley (chairman, North of England Section), F. J. Elliott (chairman, Scottish Section), P. J. C. Haywood (chairman, Western Section), J. R. Leech (chairman, Midlands Section), G. F. Hodsman (chairman, Microchemistry Group), J. E. Page (chairman, Physical Methods Group) and K. L. Smith (chairman, Biological Methods Group).

The Relation of Pure to Applied Research in Agriculture

The annual general meeting on February 29 of the Society for Analytical Chemistry was followed by the Bernard Dyer Memorial Lecture, which this year was given by Sir William Slater, secretary of the Agricultural Research Council, his subject being entitled "The Evolution of Agricultural Research". Sir William stressed that agriculture is an industry and that consequently a worker in agricultural research has to combine the qualifications of a scientist with an understanding of farmers and their problems. The growth of research institutes in which pure investigations are possible as well as the development of practical applications, and the academic prestige attached to pure research, have led to a growing tendency for universities to encourage graduates to look to pure rather than to applied research for a career. Since the Second World War the difficulty of recruiting workers to applied research has been augmented by the increasing complexity and cost of the apparatus required for such research. In agriculture there is also the problem of providing facilities for work on farm animals. Nevertheless, pure research has brought about great changes in agricultural practice, and Sir William cited the example of the modern use of hormone weedkillers. New techniques such as the use of radioactive tracers offer possibilities for taking the work further. Sir William pointed out that it is necessary to have an intermediary who can explain to the farmer what the pure research worker has discovered in the laboratory and help in the application of the knowledge on the farm, and for this the National Agricultural Advisory Service has its specialist advisory officers, who work together with the district and county officers. But such men are all too few, and there is a need for a body of similar workers based on the research institutes. Looking into the future, Sir William sees two groups working together in the agricultural research institutes: one going ever deeper into specialized investigations in the laboratory, and the other devoting itself to the immediate solution of the applied problems of the industry and maintaining contact with the Advisory Service and the farmers.

Giornale di Microbiologia: New Italian Journal of Microbiology

THE editorial board of a new Italian journal, the *Giornale di Microbiologia* (edited from the Istituto di Patologia, Via Sant'Andrea delle Dame 8, Napoli; 2,500 lire per vol. for home subscribers, and 3,000 lire for foreign), intends to collect, from the international field, only original papers which have general microbiological importance and which will interest not merely people concerned with curative and preventive medicine, but also biologists and biochemists. Specialization, says the preface to this first issue, increases, but there is also a technical and theoretical integration of the various branches of science, and works of synthesis and analysis are needed more by microbiology than by the older, more precisely delimited, sciences. This first issue begins with a paper by H. Schmidt, of the Behring Institute for Experimental Therapy, Marburg, on the problem of allergy. R. Haas and H. Wolff, of the same Institute, contribute a paper on the culture of three strains of the influenza virus on ferret kidney cells. P. Lépine, of the Pasteur Institute, Paris, writes on vaccination for poliomyelitis. E. Baldacci and A. Grein, of the Institute of Plant Pathology, University of Milan, discuss the form of the spore of *Actinomycetes* as studied by the electron microscope and the classification of the forms seen; this paper is illustrated by remarkable photographs.

T. Scotti and P. Zocchi contribute a paper, also illustrated by photographs, on the structure of the mycelium of *Streptomyces aureofaciens*. R. Tulasne, T. Terranova and J. Lavillaureux, of the Institute of Bacterial Biology of the Faculty of Medicine, Strasbourg, claim that B-vitamins, especially riboflavin, can be used instead of horse serum or ascitic fluid to obtain either L-forms of certain Gram-negative bacteria or stable cultures of L-colonies already formed. A paper by C. Castagnoli, P. Donini and F. Graziosi, of the Institute of Physics and the Microbiological Institute, University of Rome, discusses some biophysical aspects of inactivation of the BM phage through decay of assimilated phosphorus-32. M. Teti, of the Institute of General Pathology, University of Naples, discusses the effects of ultra-violet radiation on a non-inductable lysogenic strain of *Escherichia coli*; and G. Cavallo, of the same Institute, reports on the sensibility to non-ionizing radiation of a temperate phage obtained from a lysogenic strain of *Micrococcus pyogenes*. The issue ends with a paper, illustrated by photographs, by G. A. Maccacaro and A. Angelotti, of the Institute of General Pathology, University of Milan, on their electron microscope study of the filaments of *Escherichia coli*. All the papers have short English summaries. The journal is well printed and attractively produced, its photographic illustrations being particularly commendable.

Radio Noise of Terrestrial Origin: Report of the International Commission

THE eleventh General Assembly of the International Scientific Radio Union was held in The Hague during August 23–September 2, 1954 (see *Nature*, 176, 451; 1955), and Part 4 of the proceedings dealing with the meetings of Commission 4, on Radio Noise of Terrestrial Origin, under the chairmanship of Mr. J. A. Ratcliffe, has now been published (pp. 60; from the General Secretary of the Union, 42 Rue des Minimes, Brussels; 60 Belg. fr., 8*s*. 8*d*., or 1.20 dollars). In accordance with the practice of this Union, the reports of national committees on work related to the Commission are published in full, but reference to the other scientific papers submitted is limited to a list of titles and authors. A paper presented by Mr. Ratcliffe deals with the question: "What are the most easily measured characteristics of Terrestrial Radio Noise from which the interference to different types of communication systems can be determined?" This question, which was discussed at a joint meeting with Commission 6, on Radio Astronomy, defines the scope of an investigation of great scientific and practical importance; and a working party was set up to examine the problem in more detail. Some of the recommendations made at the Assembly contain suggestions for continuing research on atmospherics during the forthcoming International Geophysical Year and for the preparation of revised charts showing the general level of atmospheric noise all over the world and its variation with time and season. In view of the great importance of this work to radio communication, the Union maintains close co-operation with the International Radio Consultative Committee in this field.

History of Polish Science

DESPITE the difficulties of finance and printing, the output of scientific books and periodicals in post-war Poland has been remarkably large and the standard of the publications impressively high. Apart from numerous new journals and text-books devoted to advances of modern science, the Polish Academy of Science has brought out during the past few years several new monumental monographs devoted specifically to the history of scientific developments in ancient and modern Poland. The most recent addition to this series is Vol. 2 of the "Studies and Materials from the History of Polish Science" ("Studia i Materjaly z Dziejów Nauki Polskiej". Pp. 881. Warsaw: Polska Akademia Nauk, 1954). Of the eighteen papers which compose this volume, about half are devoted to Polish science of the sixteenth and seventeenth centuries. Three essays deal exclusively with Copernicus (Kopernik) and contain a most interesting and striking analysis of his ideas and their influence on the development of modern physics and mathematics.

Modern Development of Commercial Pesticides

A HANDSOME illustrated brochure, entitled "Fifteen Years of Geigy Pest Control", has been published by the Geigy Co., Ltd., Manchester (pp. 150; n.p.), which gives a clear account of Geigy's work on products for pest control and the way it developed out of mothproofing agents into insecticides, seed disinfectants, timber preservatives, etc. The brochure displays the many purposes for which dichlorodiphenyltrichloroethane and like products are now used and also describes its pharmacology and toxicology, its physics and chemistry, and mode of action. Besides describing these DDT insecticides and their importance, the brochure outlines recent work in this field by the Geigy Co., including that on repellants, the control of resistant flies and mosquitoes, systemic insecticides, selective acaricides, rodenticides, and on weedkillers such as 'Gesin' and the parathion preparation 'Etilon' which originated outside Geigy's laboratories. This part of the brochure is provided with a good bibliography and will be highly useful to the technical worker. The part describing the development of such products, including the experimental farm at Pfeffingen, and their marketing is of more general interest. The brochure as a whole gives an impressive picture of the way in which these products have been intensively developed in little more than a decade.

Physical Society's Exhibition

The Physical Society's annual Exhibition of Scientific Instruments and Apparatus will be held in the Old and New Halls of the Royal Horticultural Society, London, S.W.1, on the following dates: May 14, 10.30 a.m.–8 p.m. (members and Press only, 10.30 a.m.–2 p.m.); May 15 and 16, 10 a.m.–8 p.m.; May 17, 10 a.m.–5 p.m. The size of the Exhibition is expected to be similar to that of last year, but the use of the Old Hall will give extra space and make for easier access. A greater number of universities, colleges and research organizations will be taking part this year, thus increasing the proportion of purely research exhibits. The discourses this year will be as follows (each one at 6.15 p.m.): May 14, "Recent Developments in Light Sources", by Mr. H. G. Jenkins (Research Laboratories of the General Electric Co., Ltd.); May 15, "The Production of Images of Chemical Molecules", by Prof. H. Lipson (Faculty of Technology, University of Manchester); and May 16, "Colour Television: Considerations which have led to Recent Trends", by Mr. G. G. Gouriet (Research Laboratories of the British Broadcasting Corporation). As in previous years, the Society is publishing a "Handbook of Scientific Instruments and Apparatus" in connexion with the Exhibition (6*s*., or 7*s*. 6*d*. by post). All inquiries should be sent to the Society at 1 Lowther Gardens, Prince Consort Road, London, S.W.7.

Announcements

Dr. Paul R. Burkholder, discoverer of the micro-organism that produces the antibiotic chloromycetin, has been appointed director of research at the Brooklyn Botanic Garden, New York. He will take up his new duties on July 1. Dr. Burkholder is at present head of the Department of Bacteriology at the University of Georgia, Athens, Georgia.

Prof. H. C. Longuet-Higgins, Plummer professor of theoretical chemistry in the University of Cambridge, has been appointed Arthur D. Little visiting professor of chemistry in the Massachusetts Institute of Technology. During his three-months stay he will give a series of lectures on the application to chemistry of modern physical theories of atomic and molecular structure. Dr. Edwin H. Land, president of the Polaroid Corporation, has been appointed the first Fellow of the newly established School for Advanced Study at the Massachusetts Institute of Technology. The offices of the Polaroid Corporation are near the Institute, and Dr. Land will give part-time services to the educational and research activities of the Institute.

The National Vegetable Research Station, Wellesbourne, Warwick, is holding its first open day on June 5. Applications for invitations should be sent to the Station.

Two Ramsay Memorial Fellowships, normally tenable for two years and worth £600 a year plus a grant for expenses of research not exceeding £100 a year, are being offered for chemical research. One of the Fellowships will be limited to candidates educated in Glasgow. Full information can be obtained from the Joint Honorary Secretaries, Ramsay Memorial Fellowships Trust, University College, Gower Street, London, W.C.1, to whom application forms must be sent not later than April 20.

An autumn course in nuclear engineering, for graduates wishing to take up the subject, will be held at Queen Mary College, London, during September 3–October 12. Lectures will be given on nuclear physics, heat transmission, reactor theory, materials for nuclear reactors, instrumentation associated with reactors, health physics, shielding of reactors, reactor design, fuel technology, reactor kinetics and the control of reactors. Application forms, to be completed by June 1, and further information can be obtained from Dr. R. F. Saxe, Queen Mary College, Mile End Road, London, E.1.

The Ninth International Congress of Applied Mechanics will be held in the University of Brussels during September 5–13, under the presidency of Prof. F. van den Dungen, professor of analytical mechanics in the University. The technical sessions of the Congress will be in two sections: fluid dynamics and aerodynamics; and mechanics of solids (rigid dynamics, vibrations, elasticity and plasticity). The official languages of the Congress will be English and French. Those wishing to participate should register before June 30. Application forms and further information can be obtained from the general secretary of the Congress, J. Vandenkerckhove, University, 50 Avenue F.-D. Roosevelt, Brussels.

The Fifteenth International Congress of Pure and Applied Chemistry (Analytical Chemistry) will be held in Lisbon during September 9–16. The following subjects will be considered: microchemical methods, biological methods, electrical methods, optical methods, radiochemical methods, organic complexes, statistical interpretation of results, adsorption and partition methods, general, and standardization of methods and miscellaneous applications. Circulars and entry forms are obtainable from Prof. P. A. Laurent, Instituto Superior Tecnico, Avenida Rovisco Pais, Lisbon, Portugal. British persons wishing to submit papers to the Congress should send summaries, not later than May 1, to the Secretary of the British National Committee for Chemistry, Royal Society, Burlington House, London, W.1.

The Sixth International Spectroscopical Colloquium will be held in Amsterdam during May 14–19 under the auspices of the Koninklijke Nederlandse Chemische Vereniging and of the Nederlandse Natuurkundige Vereniging. Like former colloquia, this one will cover mainly emission spectroscopy (flame photometry, arc spectra, spark spectra and quantometry) and absorption spectroscopy (infrared and Raman spectroscopy; ultra-violet, visible and fluorescence spectroscopy). In addition, there will be a session on instrumentation, and two evenings will be reserved for discussions on such problems as nomenclature, normalization and documentation (the use of punch-cards, etc.). An exhibition of instruments and scientific literature will also be held. Further information can be obtained from the Laboratorium voor Analytische Chemie, 125 Nieuwe Achtergracht, Amsterdam-C4.

RECENT SOVIET RESEARCH ON MICROBIOLOGY IN THE ARCTIC AND OTHER REGIONS

DURING recent years scientists in the U.S.S.R. have given much attention to various problems of research in the North Polar area, including those of microbiology, and this field alone forms the subject of three important articles by Dr. A. E. Kriss (*Vestnik Akad. Nauk SSSR*, No. 8, 22 (1954); No. 1, 30, and No. 9 (1955)). Among previous Russian work referred to is that of B. L. Isachenko 1908–14, recorded in a monograph, "Bacterial Studies in the Northern Arctic Ocean". Dr. Kriss discusses at some length the scientific significance of micro-organisms—their high and varied enzymatic activity (for example, as bio-catalysts in different reactions) in relation both to organic and inorganic constituents of seas and oceans; low forms of vegetation, and other manifestations both on the ocean floor and in the waters above. He describes some bacterial counts at different depths in the Black and Caspian Seas, with tables and illustrations showing varying density of population, at depths down to 2,000 m. or lower. Much of this work, including notes on the Pacific Ocean adjoining the Sea of Okhotsk, is based on earlier studies by M. N. Lebedeva, V. I. Biryuzova, E. A. Rukina, etc. The research is being continued in the Sebastopol and other biological stations.

Seasonal changes and density fluctuations have been studied, with the causes thereof, so far as these can be discovered. Similar work in the United States is criticized as yielding little satisfactory result because the test samples of water were taken directly on the shore (at the end of a pier) and studied by the culture method. Samples, say the Soviet workers, should be obtained at a sufficient distance from dry land and subjected to direct microscopical examination. A table gives comparative figures of bacterial counts per millilitre of water at three stations in the Black Sea at depths down to 2,000 m. as shown by colony counts and by direct microscopy. Vertical distribution and density are also shown diagrammatically for the 'bio-masses' of micro-organisms in the deep-water parts of the Black Sea down to 2,000 m. at five stations (Lebedeva); and in addition in the oxygen zone of the same Sea 30 miles from the shore, winter and summer, down to 200 m. The first of these diagrams shows considerable uniformity down to 2,000 m.; while the second indicates that during the summer there is a relatively large maximum at 25 m., decreasing rapidly to 75 m., after which it is fairly constant; and, for the winter, a similar but smaller decline—from the surface maximum, down to about 50 m., with gradual expansion to the initial maximum down to 150 m., followed by relative constancy to 250 m.

Among the results of these Black Sea and other studies is the evident indication that bacteria constitute the primary organic material and are here associated with phytoplankton. Quantitative determination of the whole mass of micro-organisms gives some idea of the extent of their work in mineralizing dead organic matter. Starting with the fact that one microbial cell requires for its development energy approximately equal to that of the decomposition of organic matter three times exceeding its own weight, it is possible from the magnitude of the bio-mass of micro-organisms to realize in some measure the amount of organic matter in sea-water subjected to mineralization.

But the methods hitherto used for determining bacterial life in marine waters have been unsatisfactory. A new method is described by Dr. Kriss, which, though still imperfect, is claimed to surpass others so far known. The method is related to direct microscopic examination and in essence consists in lowering to various depths microscopic slides that remain in position for a specified period and are then drawn up. After suitable treatment and staining, the number of micro-colonies forming on the slides and the number of cells in each are calculated. In this way, it is possible to estimate the rate of propagation of bacteria in a given stratum of sea-water. (Though Dr. Kriss claims this as a new method, it seems to be akin to the usual technique used by microbiologists; as he admits, it is imperfect, in that it gives preference to organisms that will settle on a glass surface, and neglects those that do not.) Some results obtained by this so-called 'glass overgrowth' method are described, and the significance of the ratio of micro-organism products to their bio-mass is discussed. The need is emphasized for taking into account the widely varying conditions of season and place; for example, as between coastal and open-sea localities and between winter and summer, including also the ocean-bed where accessible. Work in the waters of the Caspian Sea is again cited by way of example of what has been done in the Soviet Union. Among other things, it has been found that about half the microbial cells (Russian *kletka*) found in the sea-bed ooze are absorbed or digested by *Nereis siccinea* during passage of lumps or particles of ooze through the alimentary tract of this worm.

Much yet remains to be done in elucidating the complex relations or links between micro-organisms and phytoplankton or phytobentos (or the corresponding zoo-types); in the study of many biogenic substances in sea-water; in increasing our knowledge of bacterial bio-catalysis; and much else. It is interesting to note that, on the floor of the Black Sea at about maximum depth, considerably more organic material easily assimilable by micro-organisms is found than on the floor of the Okhotsk Sea, the difference between them being of the order of a thousandfold.

The need for better methods of study is again emphasized by Dr. Kriss, and some of the wider aspects of this research are indicated, for example, chemical nature and constitution of sea-water; the physical aspects such as the effect of high pressure or low temperatures, combined with study of the barophyllic organisms; and other departments of science. Recent research in the Pacific at depth, or even on its floor, shows that the barophyllic type may exist in vast quantities. Special forms include those of the hydrogen sulphide depths of the Black Sea that have lately been widely investigated by Soviet workers. Other matters briefly discussed are the effect of sea-water organisms on the corrosion of structural iron and steel and concrete, and the nature and significance of marine microbial biocenoses (biocenogenesis ?).

In his second article, Dr. Kriss deals more specifically with Arctic conditions, and in addition to the earlier work of Isachenko he refers also to that of V. S. Butkevich during 1935 in the high latitudes from 82° 42′ almost to the north pole. No study at depth was undertaken, but only surface layers—presumably of ice or pack-ice. Kriss himself undertook two flights to the polar regions during July and September 1954, to establish the 'drift stations' of which the principal was called North Pole-3. Positions were lat. 88° 04·3′ N., long. 151° 16′ W., and lat. 89° 29·5′ N., long. 65° 43′ W.; the ocean depths were respectively 3,450 and 4,116 m. The July station was on the Pacific side of the Lomonosov submerged ridge, and that of September on the Atlantic side, and were thus of special interest. As already known, this ridge extends from the New Siberia islands through the north polar region to Greenland and Zembla Elsmir. In some parts of the Central Arctic, the height of these submarine mountains is more than 3,000 m.

The microbiological laboratory was set up in the hydrological building (hut or tent). Samples of water and soil were collected through holes in the ice, about 2 m. in diameter, using a special windlass made by the Arctic Institute and water-sampling bottles; also used was a core-sampler or tube designed by Alekseev (of the Arctic Institute) for ooze or mud cores. In July, samples of water were taken from the surface and at eighteen different depths down to 3,400 m. The surface water was obtained by separation near the ice floes. In September, the maximum depth was 3,700 m. In fact, the ocean floor was reached to get the cores.

The treatment of samples, filtering, preparation of cultures are described, and the results tabulated show for July and September 1954, respectively, at various depths down to 3,700 m., the number of colonies (per litre of water) and morphological state. For July, at the surface, there was continuous growth of bacilli (or rod-shaped bacteria), following which at the various depths there was considerable fluctuation in number of colonies: 1,120 at 10 m., 35 at 25 m., 490 at 75 m., 2,660 at 100 m. . . . 210 at 3,000 m., and nil at 3,400 m., in some cases with sporogenetic rods and in others with non-sporing rods (the latter being more frequent). For September, the count at the surface was of 525 colonies, with both sporing and non-sporing rods, cocci and yeasts; at 10 m. 1,995 non-sporing colonies; at 25 m. 2,485 sporing; at 50 m. 350 both sporing and non-sporing; at 150 m. 2,660, 200 m. 3,045, 300 m. 980, all non-sporing; . . . at 3,500 m. 350 sporing; and at 3,700 m. 140 non-sporing. Thus heterotrophic bacteria are found at practically all depths. It is interesting to note that at 750 m. in July the count was 70 and in September nil (the only depth in either month when the result was nil except, of course, at 3,400 m. and lower in July).

The samples of water were poured into sterilized flasks of 250 ml. into which had been previously placed narrow glass slides, and the flasks closed with ground stoppers; they were maintained for about a week at 5–7° C., and afterwards at 18–20° C. Bacterial growths—up to millions—are described; for example, from 350 colonies taken at 3,500 m. depth 5 million colonies resulted in relatively short time.

A second table gives cell counts per ml. at various depths of the north pole region during July and September and, for comparison, figures obtained from eleven out of the twenty-six stations of the north-western Pacific during May–July 1953 at depths down to 9,000 m. (for Station 26). In both cases the maxima this time are at or near the surface (50 m.) and then show a somewhat fluctuating but general decline (down to 3[illegible] counts/ml. at 8,500–9,000 m., Station 26). As might be expected, the Pacific figures are much larger, as a rule, than the north pole ones and are of the order of 100,000 to 400,000 counts/ml. from surface to 50 m. The Pacific stations were about 180–200 miles from the Kurile Islands and Kamchatka.

Methods of calculating the bio-mass content are described in a footnote, and the results given in a third table show average bio-mass of micro-organisms of usual form and cocci form—with thickened coatings—at the different depths down to 3,500 m. in the north polar region during July and September 1954, reckoned in mgm./cu. m. water. The cocci forms are 0·04 mgm. at the maximum depth up to about 0·12 at higher levels. The ordinary forms range from 0·005 mgm. at depth to 2–4 mgm. at or near the surface (0–50 m.). Some differences in form and type of organism are discussed for the north polar region as compared with the Pacific.

In regard to study of the ocean bottom near the north pole, Dr. Kriss observes that the top layer of ooze (0–2 cm.) was separated with all necessary precautions and placed in sterilized test-tubes, from which cultures were prepared, with different nutrients for the various types—inorganic salts with asparagine, calcium citrate, calcium lactate, honey, etc. The organisms included denitrifying and desulphurizing types. Reference is also made to a thionovic or thionic acid type (Russian: *tionovo-kisli*). From weighed portions of ooze suspensions were also prepared in the proportions 1/10, 1/100 and 1/200 in 0·0004 *N* sodium hydroxide spread—for direct microscope study by the Vinogradsk method—on slides to the extent of 6 sq. cm. and suitably treated for separation of the microbial forms. Rates of growth with different nutrients are noted, including also nitrite and nitrate formation, the behaviour of which was specially studied in various media. Reckoned on 1 gm. of natural ooze, microbial counts were 4–304 million for usual cells, and 170–400 million for the thick-walled cocci. Observation of these cultures from the ooze extended over three to five months.

It is thus shown that, close up to the north pole, micro-organisms exist under the perennial pack-ice practically at all levels in the water and on the bottom, with consequent continuous mineralization of organic matter and conversion of biogenic compounds; thus justifying the possibility of other forms of life, both vegetable and animal, in the highest latitudes of the Arctic region. The significance of this in connexion with general hydrological research is indicated.

The third paper by Dr. Kriss deals with a Russian expedition to the Arctic in the spring of 1955, in which leading biologists of the Soviet Union took part. It seems to have practically reached the north pole. Dr. Kriss, who accompanied the party, says that stations were established throughout the Central Arctic between latitudes 82° and 90°, including Drift Stations designated as North Pole 3 and North Pole 5. Among other things, from a hydrological point of view, the greater concentration of bacterial content in boundary or junction waters of different seas and oceans, or currents, was specially studied.

It was shown, for example, that at or near the upper and lower boundaries of Atlantic currents reaching the north polar area, the micro-organism population was several times larger than in the average of higher or lower levels.

Dr. Kriss presents some graphs showing the relation between depth (in metres) and micro-population at different seasons (June and September) as indicated by the two methods: filters, and glass overgrowth or submerged slides. There are substantial 'peak' differences with the two methods; for example, at about 100–150 m. and between 750 and 1,200 m. A map of the north polar region is also shown, giving the distribution of about 15 points where samples were taken from surface layers down to 4,000 m.

Nearly all the 1955 stations were on pack ice, and only two on the continental dip at depths of 900 and 1,850 m. Holes of 1–1·5 m. were drilled in the ice, and sampling bottles of the Nansen type were lowered to the different depths. It was evident that organisms on the ocean floor can exist under pressures up to several hundred atmospheres. It was possible in many cases to determine approximate rates of propagation at various depths. W. G. CASS

BIBLIOGRAPHY OF THE BAUXITE DEPOSITS OF THE WORLD

ALUMINIUM now competes with copper for second place after iron as the most widely used metal in commerce, and virtually all the pure alumina used for the manufacture of the metal, upwards of five million tons a year, is obtained by processing bauxite. This material is therefore an ore of the first importance, both commercially and strategically. Deposits are widespread throughout the world, though their distribution is somewhat capricious, at least from a strategic point of view. All the bauxite used by the aluminium industry in Britain is imported, and the deposits within the United States and Canada are insufficient to provide for the enormous consumption by the aluminium industry in North America.

Since Dr. C. S. Fox published, more than twenty years ago[1], a monograph on the subject containing an extensive bibliography, the literature on the subject has grown steadily. It is, however, scattered through the scientific and technical journals of many countries, so that the United States Geological Survey has fulfilled a real need by publishing a new "Annotated Bibliography of the Bauxite Deposits of the World", by Elizabeth C. Fischer (Geol. Survey Bull. 99. Pp. 221+1 folding map. Washington, D.C.: Government Printing Office, 1955; n.p.). This bibliography, which contains more than a thousand entries, was commenced originally for the use of the staff of the Survey and enlarged to meet the demand for information arising out of the greatly increased use of aluminium during the Second World War. It covers various aspects of the subject, including the origin, geology, mineralogy, chemistry, reserves and production of bauxite. A selection of papers on 'laterite' and 'lateritization' has been included, because these terms have often been used as synonyms for bauxite (that is, aluminous laterite) and the processes leading to its formation. On the other hand, accounts of the technical aspects of the mining and processing of bauxite have largely been excluded.

The entries are arranged alphabetically under authors' names, and the index is sub-divided into subject and locality headings so that references to any particular subject or area can be found quickly. There is also a useful world map showing the distribution of the principal bauxite deposits. The bibliography includes publications issued up to the end of 1950, only. Even so, it will prove extremely welcome to all interested in the subject, and it may be hoped it will be followed by a supplement.

STRUCTURE OF FRONTS IN METEOROLOGY

THE conception of a 'front', a roughly plane, sloping zone dividing air masses of different origin with the warmer air below the colder air, is a fundamental one in meteorology. The major areas of deep cloud and precipitation over the British Isles are associated with fronts, and the word has thus become a familiar one to all listeners to the weather forecasts broadcast on the radio. A front is a warm front if warmer air replaces cold air as the front passes over any point, and the converse for a cold front. Until recently, knowledge of the structure of fronts was obtained from surface observations of temperature, humidity and cloud forms, from rather isolated 'vertical' aircraft ascents, and from observations obtained by balloon-borne instruments.

During 1950–52 the Meteorological Research Flight of the Meteorological Office made twenty-three flights from its base at South Farnborough to observe the cloud structure and the temperature and humidity variations along fixed levels approximately perpendicular to the front. The flights were made following plans decided on the basis of the synoptic charts drawn at the Central Forecast Office.

The observations, in conjunction with those of the nearly simultaneous radio-sonde ascents, are analysed by J. S. Sawyer in Geophysical Memoir 96 of the Air Ministry—Meteorological Office, entitled "The Free Atmosphere in the Vicinity of Fronts: Analysis of the Observations by the Meteorological Research Flight, 1950–52" (M.O. 584*d*. Pp. 24. London: H.M.S.O., 1955; 5*s*. net). The observations show a great complexity of structure, indicating that no simple idealized structure can adequately represent an individual front, but clearly confirm the existence of sloping regions of change between two roughly homogeneous air masses. Mr. Sawyer finds that, in the region between about 6,000 and 20,000 ft. explored in the flights, there were (*a*) a frontal region, varying from 200 to 1,000 miles in width, with an average of 600 miles, across which there was a temperature difference of 5–29 deg. F., average 15 deg. F., at a fixed height, and (*b*) within the frontal region a relatively narrow frontal zone of up to 250 miles in width, average 130 miles, with a temperature contrast up to 21 deg. F., average 9 deg. F. Frontal zones of less than 50 miles wide were uncommon. The slopes of the frontal zones varied between 1 and 250 and 1 in 30, with an average of 1 in 55. This slope is much steeper than the value of 1 in 100 stated in some text-books.

A hitherto unknown feature of frontal structure revealed by the flights was the existence of a tongue of relatively dry air extending downwards along the frontal zone to an average height of about 6,000 ft. Mr. Sawyer shows that this tongue is produced, not by vertical motion down the front, but by horizontal advection of air the relative humidity of which had been reduced by descending motion some eighteen hours before in the ridge of high pressure ahead of the front. The change of humidity across a front is from moist warm air to cold dry air across a warm front, the rate of change of frost-point or dew-point being greater than that of temperature, and of a dry transition zone at cold fronts between two relatively moist air masses. The clouds observed were mainly stratiform in nature, with convectional cumulus clouds in places in all the cold fronts and in six of the seventeen warm or quasi-stationary fronts. The main cloud mass associated with the front was in the warm air, with little extension into the transition zone at nine of the twenty-three fronts examined, partly in the warm air and transition zone in seven of them; in only one was there a solid mass of cloud in the cold air.

PRESERVATION OF ANIMALS AND PLANTS BY DRYING FROM THE FROZEN STATE

By Dr. D. A. L. DAVIES and V. S. G. BAUGH
61 St. Francis Road, Salisbury, Wilts

METHODS which are being used for the preservation (*a*) of the natural colours of animals and plants possessing labile pigments, and (*b*) of the natural shape of those which are soft-bodied, leave much to be desired. Bottled specimens preserved in alcohol or formalin take up a great deal of space, and neither these nor specimens preserved in resins or synthetic polymers are readily available for close examination. Dried skins are fragile, often they retain little of the natural colour and rarely reproduce accurately the shape or attitude of the original specimens. Insect larvæ, spiders, annelids, molluscs and fungi are among the most difficult forms of life to preserve satisfactorily for examination and exhibition.

Hard-bodied insects which have stable pigments, for example, most butterflies and moths, present no difficulty; but dragonflies, except those the colours of which are due to light interference by their surface structure, lose their colours rapidly after death. These colours can be preserved by drying *in vacuo* using a water pump[1] or very rapidly, preferably at low temperature, with a high-vacuum pump[2].

Soft-bodied insects cannot be preserved in this way; even if the pressure is lowered very gradually to prevent bursting, they finally dry in a shrunken shapeless form. This difficulty can be overcome by freeze-drying, which not only maintains the natural shape and size of specimens, but also is least damaging to their colouring materials.

Freeze-drying, introduced by Florsdorf and Mudd, has become the normal method for recovering biologically active large molecules from aqueous solutions[3]. Cooling due to the rapid vaporization of ice in a high vacuum is sufficient to maintain the frozen state when solutions are dried in an ordinary glass desiccator at room temperature if the depth of the solution does not exceed a few centimetres, and there is no restriction of the absorption or condensation of water vapour. More elaborate freeze-drying equipment incorporates a heater to prevent the temperature from falling too low and slowing the rate of evaporation unduly.

When the evaporation from the surface of a frozen object is restricted, there is insufficient cooling to maintain the frozen state; caterpillars fall into this category, since their integument protects them against the drying conditions of the environment. On the other hand, it has been found that animals which normally live in water or in very moist conditions, for example, fish and marine worms or slugs and earthworms, are unable to resist the egress of water vapour.

Caterpillars can be freeze-dried in the following way: specimens are killed with cyanide, weighed and placed in the bottom of a test-tube which is partly immersed in a mixture of acetone and solid carbon dioxide at − 65° C., where they become completely frozen in a few minutes. They are then placed in an ice-box at − 15° and their temperature allowed to rise to this point, where they are in no danger of thawing nor is their vapour pressure too low for reasonably rapid drying at the pressure obtainable with a good oil pump (10–25μ mercury). A glass desiccator containing phosphorus pentoxide is precooled to −15°, the specimens transferred to it and a high vacuum applied. Specimens up to 2 in. in length (300–500 mgm.) dry under these conditions overnight, and those weighing up to 5 gm. can be dried in a few days. During this process, 65–75 per cent of weight is lost; on re-exposure to the air 1–2 per cent of moisture is reabsorbed. By the nature of the process, the products retain their shape and form, they are hard but slightly flexible, and cannot be broken by pressing between the fingers, nor is the main structure damaged by dropping on a hard floor. Whereas the colour of most specimens was quite unimpaired, the transparency of the integument is lost; and in cases where the colouring is contributed to from within, as in some green caterpillars, the final appearance is not satisfactory. In some instances green specimens retained their colour, but in others where green survived the drying process, this colour faded in a few weeks even in a sealed tube of nitrogen in the dark. Apart from this difficulty, specimens have been stored after freeze-drying without deterioration for more than a year in a laboratory atmosphere, and there is no reason for supposing that their condition is not permanent under normal storage conditions. Their final state does not differ from that of some vacuum-dried dragonflies, which have retained their natural colours for ten years.

Until the rate of drying of a particular type of specimen has been determined, it is necessary to find when constant weight has been reached. Care must be exercised when handling incompletely dried specimens, which must not be touched except with forceps cooled well below 0°, to prevent local thawing, otherwise a brown mark appears on the dried product. Rapid freezing at −65° is desirable, because slow freezing gives relatively large ice crystals which disrupt cells and body structures to give a more fragile product.

Spiders can be preserved very satisfactorily as dried specimens; they are generally less transparent objects than many insects, so that their natural colour and appearance remain quite unchanged. Difficulty was experienced initially in freezing spiders, due apparently to the presence of rather large amounts of fat in the body. When specimens were soaked overnight in trichloroethylene and then exposed to the air for the solvent to dry away, they could, however, be set on pieces of cork, frozen and dried *in vacuo* as already described.

Earthworms and slugs dried rapidly after freezing, but the dried products were opaque and white. This was due to the presence of mucous substances on their surfaces which could not be completely washed off. This difficulty has not been overcome; the specimens are perfect from the morphological point of view, but for exhibition purposes can only be recommended as better objects for colouring artificially than models. In the case of marine worms, the parapodia could be maintained in the extended condition by dropping specimens into a beaker containing ethanol at − 65° held in the acetone–carbon dioxide bath.

Although theoretically there is no limit to the size of animals which could be preserved by freeze-drying, the increasing ratio of volume to surface area in larger subjects imposes a practical limit. Among vertebrates, small fishes have been dried by freezing a dish full of water in which they were swimming and evaporating the whole contents of the dish to dryness. In this way the fins remain in an extended and natural position; however, like invertebrates which live in moist environments, the dried fishes were white and opaque. A pipistrelle bat presented no difficulty, and a mouse weighing 18 gm. dried successfully, losing 68 per cent of its weight. The mouse showed itself to have considerable protection against loss of water and took three weeks to dry; this does not make the process uneconomical, however, as a large number of specimens can be placed in one desiccator.

Of interest to botanists will be the observation that fungi are beautifully preserved in the dry state by this technique. A large toadstool weighing 30 gm. dried to constant weight in 24 hr. and became re-equilibrated to laboratory atmosphere on regaining only 2 per cent of its original weight. The greatest loss of water on drying was found among the fungi, some of which lost more than 90 per cent of their weight. It might be of interest to record in this connexion that the least loss to constant weight (50–54 per cent) was found with migratory locusts, which, on account of their relatively rigid structure, could be vacuum-dried at room temperature without freezing in 2–3 hr.

Although no deterioration has been detected after storing any specimens preserved by freeze-drying, it might be wise to inject a non-volatile disinfectant, before freezing, into those which are required for permanent collections.

A STIMULATORY ACTION OF INDOLE-3-ACETIC ACID ON THE UPTAKE OF AMINO-ACIDS BY PLANT CELLS

By LEONORA REINHOLD and R. G. POWELL

Agricultural Research Council Unit of Experimental Agronomy, Department of Agriculture, University of Oxford

It is a striking fact that, although plant growth-regulating substances produce many profound and far-reaching effects on plant cells, yet when they have been applied to animal cells little or no effect has been demonstrated. A recent report by Christensen, Riggs and Coyne[1] that indole-3-acetic acid (in relatively high concentration) stimulated the accumulation of amino-acids by mouse tumour cells was therefore of especial interest, and led us to investigate whether the auxin acts similarly on the uptake of amino-acids by plant cells.

Etiolated sunflower seedlings, six days old, were used in this investigation. Segments 1 cm. long were cut from the hypocotyls at a distance of a centimetre below the crook, and, after being washed in distilled water, were suspended in briskly aerated, buffered solutions of radioactive amino-acids, which were uniformly labelled with carbon-14. After periods varying from 0·5 to 3·5 hr. the segments were removed, well rinsed with distilled water, and freeze-dried. Their radioactivity was then determined by a technique involving wet combustion.

A very marked increase in the amount of carbon-14 incorporated from solutions of glutamic acid and glycine has been observed when indole-3-acetic acid is present in the medium. Typical experiments are summarized in Table 1. This response to auxin is a rapid one, being clearly apparent in experiments lasting less than 30 min. As Table 1 indicates, it is produced by physiological concentrations of indole-3-acetic acid. Further experiments have shown that the curve relating magnitude of effect to auxin concentration closely follows that for extension growth. The stimulation is dependent on the presence of oxygen: under nitrogen, although the figure for carbon-14 incorporation reaches approximately two-thirds of that for aerated solutions, the auxin effect is abolished.

In these experiments the uptake of glutamic acid was accompanied by the uptake of water from the surrounding medium. Water uptake was, of course, considerably greater in the presence of auxin, leading to a gain in fresh weight of approximately 13 per cent during a 2-hr. experiment as compared with

Table 1. THE EFFECT OF INDOLE-3-ACETIC ACID ON THE ACCUMULATION OF CARBON-14 FROM SOLUTIONS OF UNIFORMLY-LABELLED AMINO-ACIDS BY SEGMENTS OF SUNFLOWER HYPOCOTYL

Experiment	Experimental conditions	Indole-3-acetic acid concentration	Specific activity of segments (mμc. per m.mole carbon)†	Per cent increase in specific activity produced by indole-3-acetic acid
I. Glutamic acid 10^{-2} *M*	16 segments* in 3 ml. for 2 hr.	0	10·3 11·1	
		$8{\cdot}6 \times 10^{-6}$ *M*	17·5 19·3	72
II. Glutamic acid $2{\cdot}1 \times 10^{-3}$ *M*	12 segments* in 2 ml. for 2·25 hr.	0	53·4 53·8	
		$2{\cdot}9 \times 10^{-5}$ *M*	81·7 92·3	62
III. Glycine 2×10^{-3} *M*	12 segments* in 3 ml. for 2 hr.	0	47·4 43·2	
		$2{\cdot}9 \times 10^{-5}$ *M*	59·7 69·5	43

* The fresh weight of 10 segments is approximately 280 mgm.

† The carbon content of the segments was not perceptibly affected by the treatments.

3–4 per cent in the absence of auxin. To discover whether the uptake of water and the uptake of glutamic acid were in any way linked, experiments were carried out in which net water uptake was reduced or eliminated by the addition of mannitol to the external medium. It was found that the presence of mannitol did not depress, but on the contrary slightly enhanced, carbon-14 accumulation by segments not treated with auxin. The percentage increase in carbon-14 accumulation produced by auxin was, however, markedly diminished. It thus appears that, at least in the absence of auxin, there is no direct connexion between the uptake of water and the uptake of glutamic acid. The reduction in the auxin-induced stimulation of amino-acid uptake is possibly connected with the arrest of cell extension, which may prevent auxin from exerting its full effect.

In further experiments extracts of the segments were made at the conclusion of the experiment and their radioactive compounds examined by chromatographic techniques, using both filter paper and 'Dowex-50' columns as described by Moore and Stein[2]. It was found that only about 30 per cent of the radioactivity of an alcoholic extract is in the form of glutamic acid. No marked difference in the level of glutamic acid has been observed between auxin-treated and control segments. Colorimetric determinations revealed that the native level of glutamic acid is very low in this tissue, of the order of 25 μgm. per gm. fresh weight or less. It may be that the balance of the reactions involving glutamic acid in these cells is such that the concentration of free glutamic acid is always very low. Thus any glutamic acid entering the cells, whether in the presence or absence of auxin, is immediately metabolized. The free glutamic acid which is detected in the samples at the end of the experiments may, in fact, be recovered from the intercellular spaces and cell walls, not from the cytoplasm itself.

Table 2. EFFECT OF INDOLE-3-ACETIC ACID ON THE QUANTITY AND SPECIFIC ACTIVITY OF CO_2 EVOLVED BY SEGMENTS OF SUNFLOWER HYPOCOTYL BATHED IN SOLUTIONS OF UNIFORMLY-LABELLED GLUTAMIC ACID

(11·2 gm. tissue samples in 125 ml. 2×10^{-3} *M* glutamic acid for 2 hr.)

Treatment	μMoles CO_2 evolved	Specific activity of CO_2 (mμc. per m.mole carbon)
No indole-3-acetic acid	185 185	783 750
$2{\cdot}9 \times 10^{-5}$ *M* indole-3-acetic acid	230 247	936 878

Under the conditions of this investigation the rate of respiration of auxin-treated segments was enhanced by 20–30 per cent. When the carbon dioxide evolved was collected, precipitated as barium carbonate, and tested for radioactivity it was found that the specific activity, too, was decidedly higher in the case of the auxin-treated tissue. A typical experiment showing this interesting result is summarized in Table 2. It will be seen that, not only was the amount of carbon dioxide evolved 29 per cent higher in the presence of auxin, but this carbon dioxide was 18 per cent richer in carbon-14. It follows, therefore, that treatment with auxin had brought about a 52 per cent increase in the amount of glutamic acid respired, while only raising the all-over rate of respiration by 29 per cent.

The results reported here indicate that auxin influences the amount of amino-acids entering the cell from the surrounding medium. In the animal cells referred to earlier[1] it is thought that indole-3-acetic acid achieves its effect through its action on a transfer process. No such transfer mechanism is definitely known to exist in the plant tissue investigated here. Arisz[3] has reported active transport of amino-acids in certain highly specialized organs, the tentacles of *Drosera capensis*. Webster[4] has shown that respiratory inhibitors depress carbon-14 accumulation by bean hypocotyls bathed in solutions of labelled amino-acids; but this action may be indirect. While it seems probable, therefore, that in these cells, as in the animal cells, indole-3-acetic acid stimulates the active transfer of amino-acids (either into the cell or into some specific region of it) other possibilities have to be considered. Amino-acids may, for example, penetrate by diffusion against a considerable resistance, and auxin may bring about a lessening of this resistance. Again, it is possible that auxin does not act directly on the entry of the amino-acids: it may stimulate one or more of the processes which remove free amino-acids within the cell and which are thus responsible for maintaining an inward diffusion gradient for the acid. Should this be the correct explanation, the respiration experiment (Table 2) is significant. In the presence of auxin, glutamic acid formed a larger proportion of the substrate respired. One possible explanation is that under these conditions more glutamic acid reached the respiratory centres—that is, that auxin directly facilitated the uptake of the acid. But an alternative explanation is that glutamic acid was preferentially respired in the auxin-treated segments. This would suggest a special connexion between the action of auxin and the respiration of amino-acids (or of some derivative of amino-acids within the cell).

A fuller account of this investigation will be published elsewhere.

We wish to express our appreciation of the encouragement given us by Prof. G. E. Blackman, director of this Unit.

Electron Microscopic Observations on the Secondary Wall of the Protoxylem of *Cucurbita*

During an examination of the sieve plates of *Cucurbita* already briefly reported[1], some observations on the structure of the secondary wall in the protoxylem have been made which seem worth recording.

Since the early work of Crüger[2] a number of later workers have recorded the close relationship between the structure of the cytoplasm and the pattern of thickening in annular and spiral vessel segments.

Barkley[3] has described the development of the secondary wall in the protoxylem of *Trichosanthes anguina*, a member of the Cucurbitaceæ. According to her account the cytoplasm of differentiating vessel segments shows a banded structure, due to the development of rows of vacuoles lying between bands of cytoplasm which remains denser. The vacuoles separating the cytoplasmic bands in annular vessels are larger than those in spiral ones. During ontogeny of the vessels, the bands of cytoplasm lay down the secondary cellulose wall which then undergoes lignification. Sinnott and Bloch[4] observed a similar behaviour in *Coleus* during regeneration from parenchyma after wounding. Majumdar[5], working with *Heracleum sphondylium*, recorded additional observations on the development of the secondary wall; according to him, development of the secondary wall is preceded by the deposition of pectinaceous bases on which the secondary wall is then laid down. These bases are said to prevent the secondary wall from making intimate contact with the primary wall.

The sections presented here (Figs. 1 and 2) show the detailed structure of the secondary wall as seen in longitudinal section. Examination of these does not show the pronounced bases by which the secondary wall is said to be attached to the primary one. Although there is some indication of the lenticular-shaped base, this is very small and does not seem to prevent the secondary wall layers from making contact with the primary wall. The primary wall, due to stretching, is very thin and shows no detailed structure. The cellulose lamellæ of the secondary wall, however, are very clear (Fig. 2) and seem to be laid down in concentric rings of increasing radius. The several lamellæ appear to be firmly held together by a ground substance which may be lignin.

The lamellæ indicate, of course, the position of the cytoplasm at the

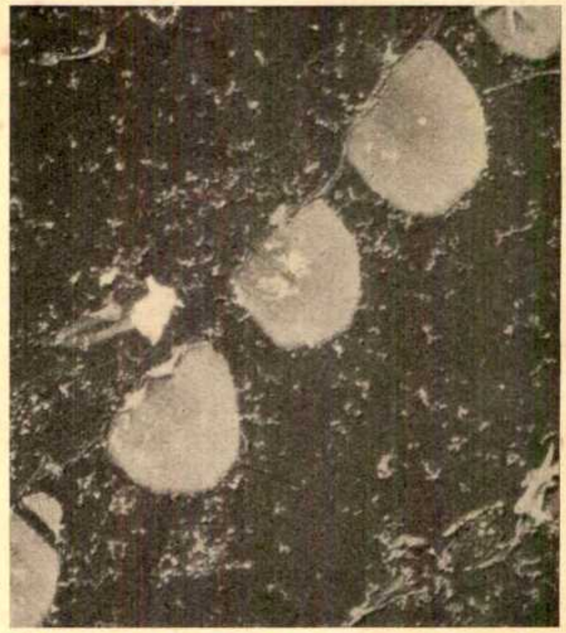

Fig. 1. Electron micrograph of longitudinal section of one wall of a protoxylem vessel element (× 3,400). Methacrylate removed. Shadowed palladium–gold. Note the thin primary wall with the superposed (presumably spiral) secondary thickenings

moment of deposition. The photograph therefore shows most clearly the enormous local expansion of the cytoplasm during the deposition of these thickening bars.

Uptake of Radioactive Phosphorus by Larvæ and Adults of Mosquitoes

Eight batches of twenty-five second instar larvæ of *Aedes aegypti* were immersed in separate beakers filled with a radioactive bath composed of 30 ml. tap water and progressively increasing amounts of a solution of radioactive disodium hydrogen phosphate ($Na_2H^{32}PO_4$). The concentrations of the radio-isotope ranged from 17 to 4,480 mμc./ml. Rolled oats (0·25 gm.) was added to each beaker to serve as larval food. Larvæ in baths with a concentration of 17–68 mμc. of phosphorus-32 showed the earliest (seven days from the day of immersion) and highest frequency of emergence as adults (approximately 60 per cent). Larvæ in baths with progressively higher concentrations of the radioisotope showed a delayed pupation, though at the end of two weeks most of the larvæ in all baths pupated except for the bath with the concentration of phosphorus-32 amounting to 4,480 mμc./ml. In concentration up to 140 mμc./ml., the emergence from pupæ took place on the average within 48 hr. after pupation, and there was a considerable mortality of emerged or half-emerged adults. This mortality was roughly proportional to the concentration of the radioactive isotope in the larval bath.

Larvæ in the bath with a concentration of phosphorus-32 amounting to 2,240 mμc./ml. remained apparently normal for more than three weeks but produced dead pupæ.

After two weeks, it was found that a very considerable proportion of radioactivity was adsorbed by the remaining larval food and debris.

The viable adults were collected each day with a suction tube, killed with chloroform vapour, dried for 24 hr. in the desiccator, weighed and their radioactivity assessed with regard to a standard reference day (day 10) of the life-cycle. The results of this investigation are shown in Table 1.

The resulting radioactivity of the adult was related to the concentration of the larval bath. It appeared that concentrations exceeding about 100 mμc./ml. of the larval bath were injurious to *A. aegypti* in so far as they greatly decreased the number of the emerged adults. The amount of radioactivity shown by the adult female was proportionately greater than in the male. While the female was on the average 1·6 times heavier than the male, the amount of radioactivity exhibited by her was about 2·5 times higher.

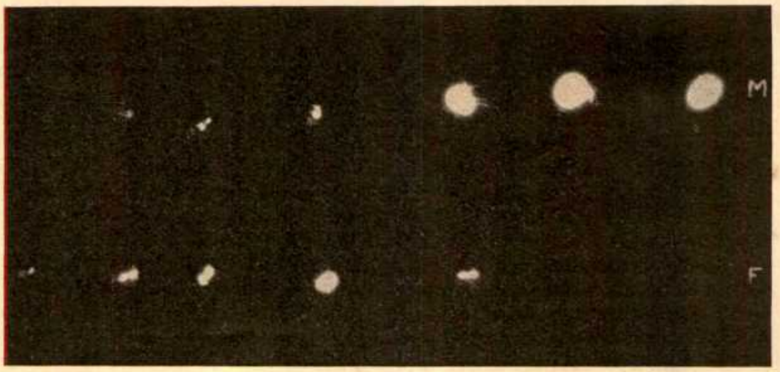

Fig. 1. Autoradiographs of a series of adult *A. aegypti* labelled with phosphorus-32 and exhibiting varying radioactivities. Males: 0·9, 1·8, 2·8, 4·2, 20·0, 32·0, 71·0 mμc. Females: 2·0, 4·3, 6·2, 16·2, 12 mμc.

Emerged adults were, after drying, mounted with 'Durofix' on a lead-rubber sheet, covered with a thin 'Cellophane' sheet and autoradiographed in a standard exposure holder on 'Kodak Crystalex' X-ray film. The time of the exposure varied between 4 and 18 hr. Autoradiographs, indicating clearly the radioactive mosquitoes and roughly the amount of their radioactivity, were obtained. A mosquito with radioactivity corresponding to 1 mμc. is clearly shown on

Table 1. Amount of Radioactivity of Adult Mosquitoes produced from Larvæ kept in Various Concentrations of Phosphorus-32

Beaker	Concentration of phosphorus-32 in larval bath (mμc./ml.)	Mean day of emergence	Mean day of counting	Sex	Numbers	Mean dry weight of mosquito (mgm.)	Mean counts per minute	Mean radioactivity of mosquito (mμc.)
Control	0	10 10	11 11	M F	12 10	5 5	1 1	0 0

9	2,240	12	13	M	1	5	50,167	71·7

the film after 12–16 hr. exposure (see Fig. 1). About five hundred mosquitoes can be mounted on the 8 in. × 10 in. standard film, and it is suggested that this simple method of detection of labelled insects might be of value for qualitative ecological studies, such as investigation of the range of flight. This is of particular interest in tropical areas where electronic equipment is not available in field conditions.

Nutritional Aspects of *Mortierella hygrophila* Linn.

PHYSIOLOGICAL studies on micro-organisms regularly isolated from soil profiles may lead eventually to a clearer interpretation of the ecological relationships of these organisms. To this end studies were initiated on the nutrition of a species of *Mortierella*. Although members of this genus are consistently isolated from soils, little is known of their nutrition.

A strain of *Mortierella hygrophila* Linn. was kindly supplied by Mrs. Turner of the Botany Department, University of Nottingham (Uni. Nott. No. 11—isolated by Claussen), and a single-spore isolation was made. The subsequent culture was employed in experiments and a subculture has been deposited at the Commonwealth Mycological Institute, Kew (Herb. I.M.I. No. 50115). Cultures were maintained on potato carrot agar, and washed-spore suspensions were employed as inoculum at a concentration of 50,000 spores/flask.

The composition of the basal culture medium was: carbohydrate source, 5,000 mgm. C; nitrogen source, 500 mgm. N; K_2HPO_4, 1·0 gm.; $MgSO_4.7H_2O$, 0·5 gm.; $FeCl_3$, 0·02 gm.; 1 ml. micro-element solution, supplying the following concentration of trace metals per litre: iron, 0·2 mgm.; zinc, 0·18 mgm.; copper, 0·04 mgm.; manganese, 0·02 mgm.; molybdenum, 0·02 mgm., twice glass-distilled water to 1 l. All chemicals were 'Analar' grade and sugars were supplied by Kerfoot and B.D.H.; *p*H initially adjusted to 6·0–6·5.

Cultures were grown in 25-ml. medium in 100-ml. Erlenmeyer flasks, and mycelial felts were washed and dried overnight at 75° C. The results were expressed as the mean weight in milligrams of five replicates.

With glucose as the source of carbohydrate the utilization of various sources of nitrogen is shown in Table 1. No growth was obtained with sodium nitrate as the source of nitrogen. However, the incorporation of 0·2 per cent yeast extract ('Difco') into the medium appeared to result in a partial utilization of the nitrate-nitrogen. Further investigation showed that the addition of small quantities of yeast extract or of peptone in a glucose medium resulted in an increase in mycelial weight above the weight due to the nitrogen content of the additions alone (Table 2).

This effect did not appear to result from a growth-factor requirement because no stimulation of growth was recorded when the following vitamins were employed singly and in combination: thiamin, riboflavine, pyridoxine, calcium pantothenate, nicotinic acid, ascorbic acid, *p*-amino-benzoic acid, biotin and inositol. No growth response was noted when yeast extract was ashed and added to a sucrose–nitrate medium. Various amino-acids were added to a glucose–nitrate medium at a concentration of 0·016 gm. acid per cent. Some growth resulted with almost all, the relative growth-rates being: L-arginine, DL-alanine, > DL-ornithine, L-glutamic, aspartic acid, asparagine, glycine, L-cystine, L-tyrosine, > DL-threonine, L-histidine, > DL-phenyl alanine, DL-valine, DL-methionine, DL-*nor*leucine, and none on DL-tryptophan. At best, growth was not as good as with peptone. Apparently there was no indispensable amino-acid.

Table 1

Nitrogen source	Mycelial weight on: Basal medium + glucose	Basal medium + glucose + 0·2 per cent yeast extract	Basal medium + sucrose + 0·2 per cent yeast extract
$NaNO_3$	0·0	102·1	77·2
$NH_4H_2PO_4$	14·6	75·8	20·3
$(NH_4)_2SO_4$	9·6	65·3	14·9
NH_4NO_3	9·2	81·1	13·7
Glycine	36·5	115·8	18·0
Peptone	147·3	141·6	140·2
Yeast extract 0·2 per cent	81·9	—	—

Table 2

Source of nitrogen	Mycelial weight on basal medium + glucose
$NaNO_3$	0·0
Yeast extract, 0·2 per cent	88·2
$NaNO_3$ + yeast extract, 0·2 per cent	161·7
Peptone, 0·1 gm.	62·7
$NaNO_3$ + peptone, 0·1 gm.	94·9
Peptone, 0·01 gm.	6·4
$NaNO_3$ + peptone, 0·01 gm.	23·0

The replacement of glucose with sucrose in the basal medium plus yeast extract provided a similar pattern of nitrogen utilization (Table 1).

In order to utilize nitrate-nitrogen, *M. hygrophila* may require a source of preformed nitrogen compounds to provide sufficient energy for the production of an adaptive nitrate reductase enzyme. This explanation appears to be only partially true because with decreasing peptone additions mycelial weights also decrease.

The availability of various sources of carbohydrate to *M. hygrophila* was determined on a medium containing sodium nitrate and 0·2 per cent yeast extract. The results are shown in Table 3.

Table 3

Carbohydrate source	Mycelial weight on basal medium + $NaNO_3$ + 0·2 per cent yeast extract
Glucose	106·9
Maltose	87·2
Raffinose	25·3
Lactose	24·5
Sucrose	20·9
Arabinose	17·5
Starch	32·6
Glycogen	20·2

Macerated, washed Whatman No. 50 filter paper was added to the basal medium containing sodium nitrate and yeast extract to test for possible cellulolytic activity. *M. hygrophila* was not able to grow on this medium, even when 0·05 per cent 'starter' glucose was added.

This work was carried out during the tenure of a research fellowship in the University of Nottingham.

Eggs of *Lestinogomphus africanus* (Fraser)

In June 1955 I had the good fortune to obtain batches of eggs from two females of the archaic dragonfly *Lestinogomphus africanus* (Fraser) taken near Kuru, Northern Nigeria. These eggs presented a feature which has apparently not hitherto been described in the Odonata, although similar structures are known in certain genera of the Ephemeroptera. The posterior pole of the egg was produced into a coiled filament about 30 mm. in length, at first tightly wound and forming a small cap over the end of the egg, but opening out into a loose spiral on contact with the water.

A fuller description of the egg and of the early nymphal stages will shortly be published elsewhere by myself and Mr. A. E. Gardner, who has reared some of these eggs up to the third instar, so no further details are necessary here.

Morgan[1] described and figured very similar structures in the egg of the mayfly *Stenonema*, and these have been discussed by Needham, Traver and Hsu[2]. They are generally considered to be an adaptation to life in rapidly flowing water and to serve for anchorage, although eggs both with and without special anchoring structures can be laid in both rapid streams and quiet ponds.

Dr. P. S. Corbet, of Jinja, Uganda, informs me that he has very recently obtained some eggs from *Ictinogomphus ferox* (Rambur) and finds that they have filaments similar to those shown in some sketches of *Lestinogomphus* eggs that I had sent him; it therefore appears possible that these filaments may be found in a number of different genera of the Gomphidae. Dr. Corbet has found fully grown nymphs of both *Lestinogomphus* and *Ictinogomphus* in sheltered muddy portions of lakes in Uganda, and considers that the presence of these filaments may be evidence of rheophilic ancestry in species at present able to live in a stagnant and muddy environment. In Nigeria, *Ictinogomphus* breeds in muddy ponds; but the *Lestinogomphus* in question were taken beside a flowing stream, so it would appear that the latter species is able to breed in both running and stagnant water.

I am grateful to Dr. Corbet for permission to quote his observations.

Ink Ejection by Cephalopoda

It has long been said that the ink discharged by the great majority of cephalopods is ejected as a black cloud, under cover of which the animal may escape from a threatened attack. That this is false is apparent to anyone who has watched the phenomenon. The ink (of such cephalopods that I have seen) initially does not form a cloud, but remains a discrete, dark, viscous mass; water turbulence breaks up the mass, dispersing it in the form of streaks indicating the direction of the current flow, and even in a small volume of water such as an aquarium tank, cloud formation takes place only after some considerable time. The importance of this may not be readily apparent in a brightly illuminated aquarium; but the following observation, made under conditions of reduced light intensity one evening aboard the Singapore Regional Fisheries Research Vessel *Manihine* (October 1955), appears to present the true interpretation of this escape reaction.

I attempted to catch a small (unidentified) squid, some three inches long, which was being kept alive in a large, light-coloured wooden tub. The squid displayed evidence of agitation as it was manœuvred into a suitable position for capture, changing colour rapidly in the manner which is well known. When my hand was within about nine inches of the animal the squid assumed a dark coloration and appeared to become stationary. I seized the dark object, but it proved to be nothing more than a volume of ink; the squid was found to be at the opposite side of the tub. On repeating the attempted capture, I was able to see that, after assuming the dark coloration, the squid discharged a quantity of ink sufficient to produce a discoloured volume of water of similar size to the squid itself, simultaneously becoming pale in colour and moving away rapidly around the perimeter of the tub. Although I had been anticipating a discharge of ink during the first attempted capture, so efficiently had the operation been performed, and so intent had I been on the capture of a dark-coloured creature, that I had failed completely to see the escape of the squid in its light-coloured guise. I had the advantage of viewing the events laterally: a 'natural' enemy would have suffered the additional complication of having the ink discharged between it and the squid.

I have not yet had the opportunity of comparing with this the behaviour of other cephalopods, but in the case of the specimen examined the important features of the escape reaction are: (1) the assumption of a dark coloration immediately before (2) the discharge of a quantity of ink sufficient only to discolour a volume of water of similar size to the animal itself, this ink functioning primarily as a decoy, but also masking to some extent (3) the rapid change of the animal to a lighter colour and (4) the rapid departure of the animal from the scene of the impending attack.

Variation in Mortality with Differences in Humidity among Mosquitoes exposed to BHC, Dieldrin and DDT

Since 1949 a long series of trials of residual insecticides has been carried out by this Unit at Taveta, Kenya, using the trap-hut method originated by Thompson[1]. In a number of the trials carried out since 1952, using BHC and dieldrin, a pronounced seasonal effect has been observed. During the dry season, the percentage mortality among female anophelines entering the houses has frequently declined, increasing comparatively rapidly at the onset of the next rainy season. This has been noted in huts lined with an impervious surface (banana leaf) treated with dieldrin and in others with reed roofs

and walls plastered with mud, and treated with either dieldrin or BHC. The phenomenon has not been noted with DDT in this series of trials; but it possibly occurred in the earlier set conducted in the same locality by Davidson (ref. 2, Table 3) using DDT oil-bound suspension on a mud-and-gravel wall. Hocking[3] observed an increase in kills in a tent treated with DDT dissolved in kerosene when heavy rain fell, but his observation seems to have been overlooked.

It is suspected that rising atmospheric humidity is the reason for increasing mortalities in our trials. Throughout these experiments, regular tests have been made with blooded female *Anopheles gambiae* and *A. funestus* suspended in the huts in gauze cages. One cage has been fixed so that one side is about ¼ in. from a wall but not touching it; the other has been hung from the roof, about 5 ft. from walls or thatch. The results of a series of tests in three huts, all with mud walls, during the period October 1954–March 1955 are given in Table 1. This period comprises the short rains, short dry season and beginning of the long rains; but the season in question was remarkable for heavy unseasonal rains between February 2–8. Table 1 gives the percentage mortality of female vectors for each date, together with the total rain recorded during the previous week one mile distant at the offices of Taveta Sisal Estate, Ltd., to which I am indebted for these figures.

The kill in the huts treated with BHC during November 23–24 is probably due to increased humidity preceding 2·52 in. of rain during November 25–27. Apart from these two entries, the relation between rain and high mortalities is consistent.

These observations were followed by daily exposure of mosquitoes in the hut treated with dieldrin. These results are given in Table 2. Direct readings of relative humidity were commenced; but the hygrograph used was afterwards found to be unserviceable. As the rainy season becomes established, the relation between precipitation and mortality becomes less intimate, consonant with the generally high level of humidity at this season.

These experiments measure only the vapour or, in the case of dieldrin, particulate action of the insecticide[4], and similar results have been obtained with dieldrin in Mexico by Bordas and Navarro[5]. However, the seasonal variation among mosquitoes entering the huts naturally, which is mentioned above, has been detected in huts no longer showing any vapour or particulate action, and evidently the effect is also apparent in mosquitoes contaminated by direct contact. A detailed account of the experiments will be submitted for publication elsewhere; but the purpose of this communication is to direct attention to a factor which may have important practical effects in two ways. First, an insecticide-spraying routine which is quite adequate in a coastal or forest area with constant high humidity may fail when applied in a dry inland zone where breeding of anophelines takes place in river pools, irrigation water or artificial containers. Secondly, when conducting tests to determine the persistence of a treatment, or to detect possible acquired resistance to insecticides, misleading results are possible unless test conditions are standardized with regard to humidity.

This work was undertaken as part of a scheme authorized by the Colonial Pesticides Committee and financed from the Colonial Development and Welfare Fund.

Occurrence of *Achtheres percarum* Nordmann in English Waters

Achtheres percarum Nordmann[1] is a copepod crustacean well known as an ectoparasite in the buccal cavity and on the gills of perch, pike and pike-perch from Germany, Italy, Czechoslovakia, Finland and the U.S.S.R. as far east as Lake Baikal. Until recently, however, there has been no authentic record of it in the British Isles. Gurney[2] pointed out that T. and A. Scott's record[3] of it in the Ray Society monograph on British Parasitic Copepoda was an error due to a misidentification of specimens of *Salmincola thymalli* (a parasite of trout).

It was therefore of considerable interest to find that parasites taken from the mouth of a perch from the Kennet and Avon Canal at Burfield by Mr. S. Prudhoe on June 17, 1954, belonged to this species, and in November, quite independently, one of us (F. W. K. G.) found them, also on perch, in the River Colne, near Rickmansworth, two fish trapped during an investigation of the food of coarse fish being infected. Further samples from three stations, covering six miles of the River Colne and Grand Union Canal system, confirmed that perch were the only hosts of this parasite. Pike, roach and gudgeon were also present but not attacked. Among the small number of perch examined (240 specimens) the overall percentage of infected fish from the three stations investigated was 7½ per cent.

Seven per cent of the perch were infected at the highest station (*A*) in the River Colne, just before its entry into the Grand Union Canal two-thirds of a mile above Rickmansworth. Below Rickmansworth the old course of the River Colne forms a series of intermittent channels linked with the Grand Union Canal. In one such channel at the second station (*B*) two and a half miles below station (*A*) and immediately before its reunion with the canal at the sewage works near Maple Cross, no fewer than 27 per cent of the perch population were infected. Three and a half miles farther down at station (*C*), in the Colne near Denham Studios, one hundred and twenty-four perch were examined and found entirely free from this parasite.

All sizes of perch (10·0–32·0 cm. in length) were attacked by the parasite; but the percentage was much greater among the larger fish (longer than 14·0 cm.).

Individual hosts frequently bore one or two parasites, but the larger parasitized fish (more than 20·0 cm.) had two or more and in one case ten parasites per host. According to Schäperclaus[4], the number of parasites per host is much greater on the Continent of Europe.

In perch from the River Colne the parasite was only found in the buccal cavity and never on the exterior of the body. In some cases the parasite attached itself to the gill bars, rakers or palate, but was most frequently found on the edge or tip of the tongue, where the parasite would seem most vulnerable to damage when the host is feeding.

There is the possibility that *Achtheres percarum* Nordmann has been accidentally introduced into Britain with perch, pike or pike-perch, all of which, according to records available since 1937, have been imported intermittently into south England in small numbers from Holland, Germany and Italy for stocking inland fisheries and aquaria.

Sporulation of Fungi inside the Plant Host Cell

The sporulation of fungi usually occurs when suitable conditions of nutrition and aeration are provided. It appears that whereas the conditions inside plant cells commonly admit of the formation of resting spores, they are, in general, less suitable for the formation of non-resting ones. Thus in Plasmodiophorales, the plasmodia develop into resting spores within the host cells, whereas the active swarm spores are typically formed outside the host. Again, in Pythiaceae, Albuginaceae and Peronosporaceae, the resting spores (zygotes) may be formed inside the host tissue; but the zoosporangia and conidia are usually formed outside it. The powdery mildews, smut and rust fungi, in different ways, exemplify this same phenomenon. So far as I know, conidia as defined by Mason[1] are rarely reported to be formed inside plant cells and, more particularly, at some depth in a tissue matrix. In these few cases where they have been reported, they typically occur inside the vessels, for example, microconidia of *Fusarium oxysporum cubense* inside the spiral vessels of banana plants[2], and the presence of microconidia of *Fusarium oxysporum conglutinans* has been described in the xylem of the cabbage plant[3]. It may be that it is not uncommon in the experience of pathologists to encounter conidia in plant cells; but the phenomenon does not appear to have been given much attention and it has not been dealt with in standard texts.

In the course of my present experimental work on fungal rots of potato tubers during storage, conidia of a pathogen were found inside host tissue. It was observed that a synergistic effect between *Rhizoctonia solani* Kühn and *Fusarium solani* sensu Snyder and Hansen resulted, under certain conditions, in the formation of pimple-like outgrowths. These 'pimples' were caused by the division and enlargement of the parenchymatous cells beneath the cork layers. The periderm also divided and enlarged to cover this tissue extension (Fig. 1). At a later stage, *F. solani*, proceeding from the inside of the tuber, invaded the pimples and sporulated abundantly inside the elongated parenchyma cells, but conidia were not

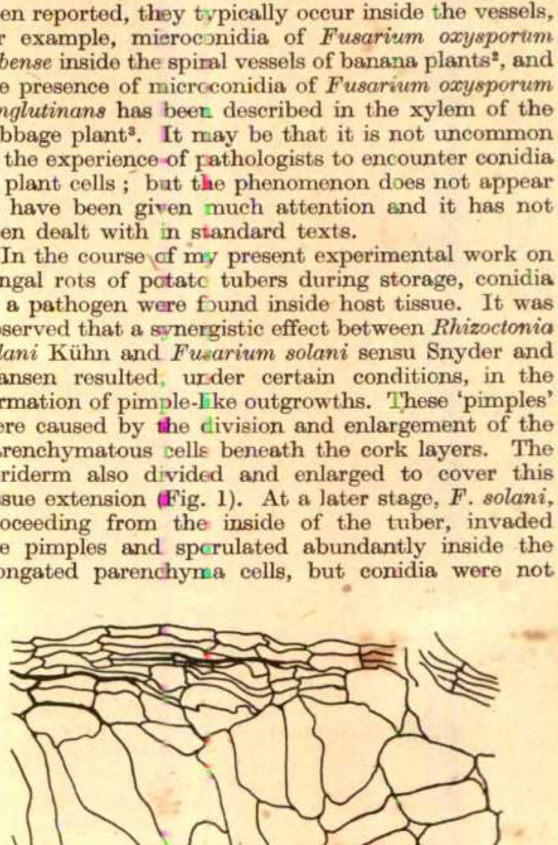

Fig. 1. A part of a 'pimple' showing the elongation of the parenchyma and cork cells, before fungus invasion. (× 100)

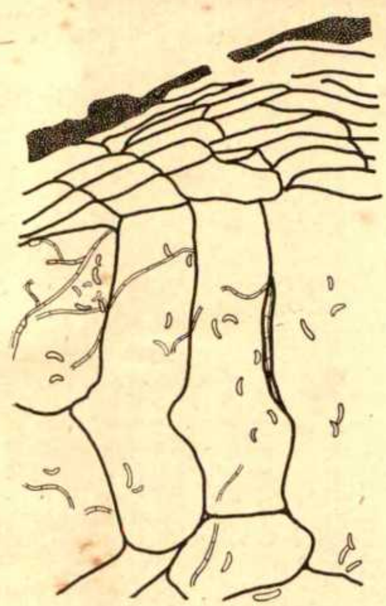

Fig. 2. A part of a 'pimple' after *Fusarium solani* invasion, showing hyphæ and microconidia inside the elongated cells. (× 250)

observed in other adjacent sub-superficial parenchymatous tissues. The conidia observed were mostly microconidia with a few macroconidia (Fig. 2). Measurements of conidia showed that those formed inside the host were significantly smaller than those formed on ten-day old cultures on potato dextrose agar.

The reason for the formation of conidia in the pimples and not in other parts of the plant is not known; but it may be correlated with the factor which stimulates the division of the cells. The low number of macroconidia and the smaller size of spores inside the cells may be due to different factors, among which light may be important[4].

I wish to express my thanks to Prof. C. W. Wardlaw, under whose supervision this work was done.

Nuclear Vacuolation in the Liver Cells of Depancreatized Baboons

SEVERE nuclear vacuolation has been observed in the liver cells of human diabetics[1-3], of infants suffering from malnutrition[2] and of patients suffering from various diseases[2-5], but has not been reported in experimental diabetes, whether produced by pancreatectomy or by alloxan in laboratory animals. The factors promoting nuclear vacuolation still await investigation.

In our laboratory, depancreatized baboons rapidly develop all the manifestations of diabetes. The blood sugar rises to more than 500 mgm. per 100 ml., accompanied by 2–3 gm. per cent of glucose in the urine and severe ketonuria. Diabetes in the baboon can be controlled by insulin.

Serial liver puncture biopsies performed by the technique previously described[2] have revealed that nuclear vacuolation does not occur in baboons in a variety of experimental situations. Within four days after withholding insulin from depancreatized baboons, however, some degree of nuclear vacuolation is to be found in the liver cells adjacent to the portal tracts and, by the end of the seventh day, almost all cells throughout the lobule contain abnormally vacuolated nuclei (Fig. 1).

When fully developed, the vacuolated nucleus is characterized by a thick nuclear membrane to which is adherent the still prominent nucleolus and a thin rim of chromatin. The vacuole is filled with glycogen and occasionally contains a small globule of sudan-positive material. The concentration of nuclear glycogen contrasts with the paucity of cytoplasmic glycogen. Indeed, the nuclear reactions observed in the liver cells of depancreatized baboons are unmistakably similar to those present in the livers of human diabetics.

Although the number of vacuolated nuclei can be reduced by the administration of insulin, once these nuclei have appeared in the livers of depancreatized baboons, some are always to be found whether or not the diabetes is eventually controlled. Indeed, even in man when diabetes is well controlled dietetically and with the aid of insulin, a few vacuolated nuclei have always been found in the liver.

The presence of vacuolated nuclei cannot be correlated either with the severity of the glycosuria or of the ketonuria. Apparently, in depancreatized baboons, deprivation of insulin for a minimum period of four days initiates a process which profoundly alters the structure of the liver nuclei. Once developed, insulin can reduce the number but cannot abolish completely the vacuolated nuclei. Apparently, such nuclei remain as a permanent stigma of a temporary but complete deprivation of insulin.

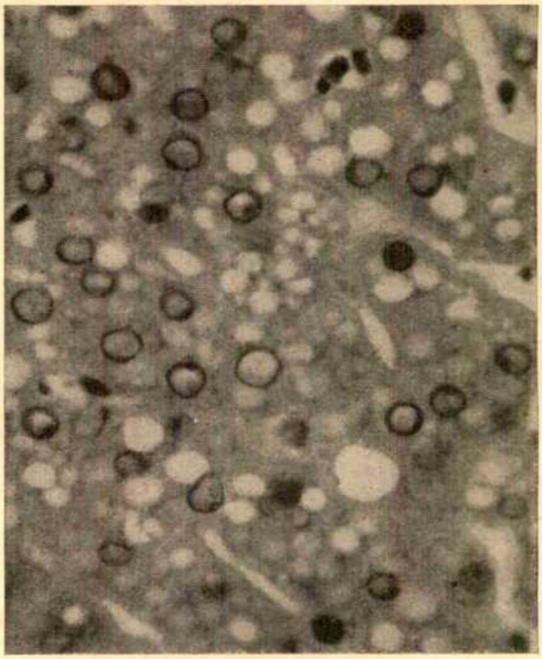

Fig. 1. Liver cells of depancreatized baboon showing numerous vacuolated nuclei each containing a large globule of glycogen

We wish to express our appreciation to Drs. J. C. Allan and A. J. Leonsins, of the Department of Surgery of this University, for depancreatizing the baboons.

Pseudo-Cholinesterase in the Central Nervous System of the Frog

A RECENT reference in the literature[1] suggests that there may be no pseudo-cholinesterase in the central nervous system of the frog. The conclusion is based on two kinds of evidence: (1) with Warburg manometric technique the tissue did not split significant quantities of benzoylcholine; and (2) there was evidently no splitting of butyrylthiocholine when the tissue was examined histochemically by Koelle's[2] modified technique. Our own evidence suggests that this conclusion is incorrect.

Many studies[3] have shown that benzoylcholine is for many species, notably the ruminants, not a suitable substrate for the demonstration of pseudo-cholinesterase. Butyrylcholine is for this reason the substrate to be preferred in comparative studies. Using butyrylcholine, one of us (D. C. H.) has found that frog tissue (homogenate of brain, spinal cord and sciatic nerve) can split butyrylcholine, and the results clearly suggest the presence of both true and pseudo-cholinesterase (see Table 1).

Table 1

Tissue	Substrate (10 m*M*)	µl./hr./mgm. tissue No inhibitor	DFP 10^{-6} *M*
Brain	Acetylcholine	14·2	12·9
	Butyrylcholine	3·5	0
Spinal cord	Acetylcholine	18·4	14·6
	Butyrylcholine	7·3	0
Sciatic nerve	Acetylcholine	1·2	1·3
	Butyrylcholine	about 0·7	0
Mixed nervous tissue*	Acetylcholine	12·0	10·9
	Butyrylcholine	2·7	0

* Mixed tissue = combined brain, spinal cord and sciatic nerve.

Moreover, as mentioned earlier[4], it can be shown that sections of frog retina split butyrylthiocholine when the incubation system is that first described by Koelle[5]. Here, and in the spinal cord of the frog, the quantity of enzyme splitting butyrylcholine seems to be small; but it is demonstrable. An interesting finding is that both true and pseudo-cholinesterase may be present in the supporting cells of the optic nerve trunk.

These results underline the care required in attempting to characterize an enzyme by its activity towards one substrate only; this is particularly true of the use of benzoylcholine as a test for pseudo-cholinesterases, the specificity pattern of which varies markedly from species to species.

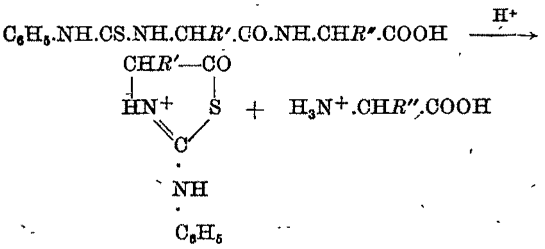
Mechanism of the Phenyl *Iso*thiocyanate Degradation of Peptides

A STUDY of the mechanism of the phenyl *iso*thiocyanate degradation of peptides[1] has made necessary a revision of our earlier formulation of this reaction. It has been found that the compound initially formed in the acid-catalysed cleavage of a phenyl thiocarbamyl peptide is not the expected 3-phenyl-2-thiohydantoin derivative of the N-terminal amino-acid, but instead the isomeric 2-anilino-5-thiazolinone.



$$C_6H_5.NH.CS.NH.CHR'.CO.NH.CHR''.COOH \xrightarrow{H^+} \begin{array}{c} CHR'\text{—}CO \\ | \qquad\quad | \\ HN^+ \quad\;\; S \\ \diagdown \;\; \diagup \\ C \\ \vdots \\ NH \\ | \\ C_6H_5 \end{array} + H_3N^+.CHR''.COOH$$

This intermediate is clearly distinguishable from the thiohydantoin by its ultra-violet absorption curve (Fig. 1) and by its behaviour on paper chromato-

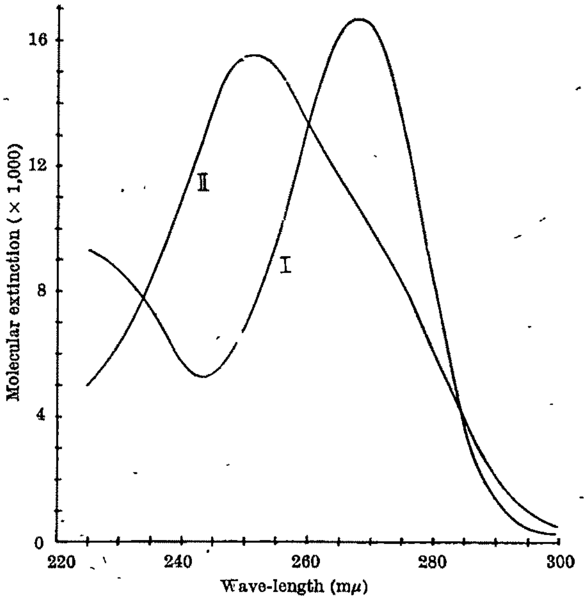


Fig. 1. Ultra-violet absorption curves of 5-*iso*butyl-3-phenyl-2-thiohydantoin (I) and 2-anilino-4-*iso*butyl-5-thiazolinone (II) in ethanol

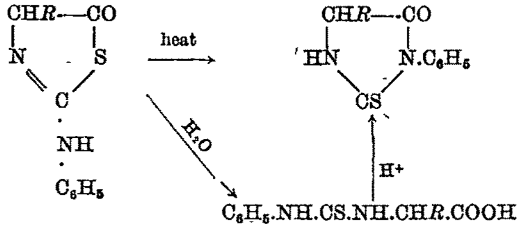
graphy. Its marked instability explains why it has eluded discovery earlier. Thus, for example, recrystallization converts it to the isomeric 3-phenyl-2-thiohydantoin. Furthermore, it has been found that the thiazolinone can be converted to the thiohydantoin along two different routes. Under anhydrous conditions the conversion takes place as an intramolecular rearrangement, whereas in aqueous solution the thiazolinone is first rapidly hydrolysed to the phenyl thiocarbamyl amino-acid, which later slowly undergoes ring closure to the thiohydantoin.



This reaction mechanism offers an explanation for some discrepancies noted by several workers. Thus the remarkably large difference in the rate of cleavage of phenyl thiocarbamyl peptides in non-aqueous[1] and in aqueous acid solution[2] is only apparent, since in the latter instance the reaction observed was not the cleavage of the peptide, but actually the conversion of the phenyl thiocarbamyl amino-acid to the phenyl thiohydantoin. Furthermore, the appearance of multiple spots on paper chromatograms as the result of a single step in the degradation can probably in many instances be explained by the presence of the intermediates. For the same reason the extent of cleavage of the peptide may appear low when calculated from the yield of thiohydantoin.

A full account of this work will be published in *Acta Chemica Scandinavica*. It has been aided by a research grant from Eli Lilly and Company.

Serum Magnesium Changes in Hibernation

HYPOTHERMIA and hibernation have been subjects of increasing interest in recent years, yet there is a critical lack of observations on the biochemistry of these states. High levels of magnesium in serum have been related by several investigators to hibernation and cold exposure[1]. In the present studies levels of serum magnesium and other electrolytes, and serum specific gravities, were compared in bats in several series including both hibernating and non-hibernating conditions.

The first species (*Eptesicus fuscus*) was collected in hibernation in a cave. One group was bled while still dormant and the other group after they were maintained and fed in a flight cage for four days. The second species (*Myotis lucifugus*) was obtained from a summer colony and from a cave in winter hibernation. The specimens were bled after periods of hibernation varying from 1 hr. to 9 weeks. The serum potassium determinations by flame photometry showed no significant changes due to hibernation. For other electrolytes recently described micromethods were used; for the calcium, the method of Natelson and Penniall[2] and for magnesium the method of Orange and Rhein[3]. The serum calcium-level during hibernation decreased, whereas the cell/plasma ratio and the specific gravity of the serum increased slightly but not consistently. The serum magnesium in all hibernating groups was 50 per cent higher than in the active animals, which normally showed a level of 4·1 mgm. per 100 ml. *P* values ranged from 2 to less than 1 per cent. The specific-gravity results indicated this was not a passive process.

The increase of serum magnesium in bats occurred after only one to two hours of hibernation and was found by the time the œsophageal temperature had dropped to 13° C. There was no significant increase in serum magnesium when the œsophageal temperature had dropped to only 17–20° C. Awakening from hibernation does not require a lowering of the serum magnesium, since there was no reduction of serum magnesium when body temperature was raised to 18° C., a procedure which required 5–8 min. However, one hour after arousal from hibernation, the serum magnesium had dropped. The increase in serum magnesium in hibernation is uninfluenced by season.

This research was aided by grants from the Central Scientific Fund of the College of Medicine, State University of Iowa, and National Science Foundation, Washington, D.C.

The 'Seebeck Effect' in a Purely Ionic System

IN a recent discussion of the transducing mechanism responsible for thermal sensibility, it was argued that, if the free nerve-ending and the extracellular fluid surrounding it could be regarded as a thermocouple, a single sensory mechanism could account for the sensations of 'warm' and 'cold'[1]. A calculation of the potential difference associated with temperature gradients in homogeneous electrolytic solutions indicated that a thermoelectric effect large enough to account for the depolarization of a nerve fibre would almost certainly have to arise at the interface between the two phases of such an ionic thermocouple. Such an effect, analogous to the Seebeck effect for metallic thermocouples, has not previously been demon-

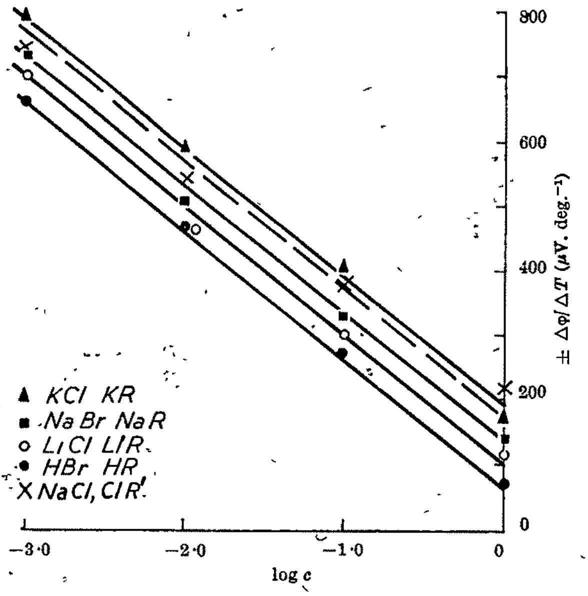

Fig. 1. Variation of $\pm\,\Delta\varphi/\Delta T$ with log c for cation-(R) and anion-(R') exchange resins. KR represent the cation resin in the potassium form, etc. The observed values of $\Delta\varphi/\Delta T$ were negative for the anion resin. The full and broken lines have the slope $2{\cdot}303\,R/zF$; the broken line refers to the anion resin

strated, so far as we are aware, for purely ionic systems. The following results show that the effect exists, and is of appreciable size.

As it was essential for the solid phase of the suggested ionic thermocouple to consist of an immobile framework of ions in which mobile ions of opposite sign are held, sheets of anion- and cation-exchange resins ('Permaplex A 10' and 'C 10' respectively) prepared by the Permutit Co., Ltd., were selected. Strips of the resin 1 cm. wide, 0·5 mm. thick and 10–16 cm. long were bent into a U shape and covered with 56° C. paraffin wax to prevent loss of moisture by evaporation. The cell used for the cation exchange resin was:

$$\begin{array}{c|c|c|c|c} \text{Ag, Ag}X & \text{Aqueous } MX \text{ conc. } C & \text{Resin in } M^+ \text{ form} & \text{Aqueous } MX \text{ conc. } C & \text{Ag, Ag}X \\ & T^\circ & T^\circ & T^\circ + \Delta T^\circ & T^\circ \end{array}$$

where X represents a halogen anion. The electrodes were introduced solely in order to make measurements of potential changes in the resin-electrolyte system possible, and made no net contribution to the e.m.f. developed by the cell. A similar cell was used for the experiments with the anion-exchange resins. The results were not intended to be precise; the main purpose of the work was the demonstration of the reality of the effect.

In general, the measured e.m.f., $\Delta\varphi$, was a linear function of the temperature difference ΔT across the strip, and the thermoelectric power $\Delta\varphi/\Delta T$ was reproducible for a given strip. Individual strips of the same nominal composition did not always show identical values for the thermoelectric power, probably because of slight differences in the concentration of the mobile ion in the solid phase. When the resins behaved reproducibly, the thermoelectric power of the cell was a logarithmic function of the concentration of the common ion (M^+ in the above cation-resin cell) in the electrolyte. This is seen in Fig. 1, where the experimental results are summarized. The values of $\Delta\varphi/\Delta T$ shown represent average values for this quantity over the range 20–55° C. and are accurate to about 0·02 mV. deg.$^{-1}$.

The variation of the thermoelectric power with the concentration of the common ion is of the form expected if the resin-solution interface is regarded as analogous to an electrode reversible to X^- or M^+ ions. On this model, the interfacial potential developed for unit change in T should change by approximately $2{\cdot}303\,R/zF$ for a ten-fold change in the concentration of the common ion in the electrolyte, where z represents the algebraic charge on this ion. If the cell illustrated is taken as an example, the electrode on the right would be positive if M^+ ions were released from the resin on heating, since the resin side of the interface would then become negatively charged. The converse should be true for a cell containing an anion-exchange resin. The straight lines in Fig. 1 show the theoretical value of the slope drawn as closely as possible to the experimentally determined points. There was, therefore, in these systems a contribution to the total thermoelectric power, dependent upon concentration, which arose at the resin-solution interface, that is, a contribution analogous to the Peltier e.m.f. in a metallic thermocouple. The remainder of the measured e.m.f. was made up of two thermal diffusion potentials (analogous to Thomson potentials) in the homogeneous phases in which temperature gradients existed, namely, in the resin strip and in the salt bridges. These were probably small in comparison with the effect at the interface; that in the electrolyte was probably of the order of tens of microvolts per degree.

If the mechanism of thermal sensation in free nerve-endings has any relation to this model system, a reasonable value for the thermoelectric power developed would be about 0·25 mV. deg.$^{-1}$. Changes in the nature of the solid phase could not change this value much. Since a voltage change of 10–15 mV. is required to initiate a propagated impulse in a wide variety of excitable tissues, it is improbable, therefore, that a single free nerve terminal could respond with the required sensitivity on the basis of this model. This does not necessarily rule out the hypothesis, since depolarization of an axon or cell body of nerve cells may be accomplished by the spatial or temporal summation of local depolarizations, individually or of a smaller magnitude than the minimum e.m.f. required for the 'triggering' of the parent axon or cell body. For the detection of a 1 deg. C. difference in temperature some forty to sixty locally propagated impulses of 0·25 mV. would be required to be summed at one stem nerve fibre to evoke a discharge. This is not an unreasonable number; in fact, many stem nerve fibres give rise to more than sixty nerve terminals.

We are indebted to Dr. T. R. E. Kressman, of the Permutit Co., for advice and for samples of the 'Permaplex' resins. The equipment used at Oxford was obtained with a grant to Dr. G. Weddell from the Rockefeller Foundation, which is gratefully acknowledged.

Flame Spectrum of Barium: Red and Infra-Red Bands

The diffuse bands appearing very strongly in the flame spectra of the alkaline-earth metals have been identified as due to the hydroxide radicals, CaOH, SrOH and BaOH. This identification is based on the work of James and Sugden[1] on hydrogen–air flames, employing photometric methods, and on work on isotope shifts with deuterium, which have been obtained for CaOH by Gaydon[2] and for SrOH by Huldt and Lagerqvist[3]. The flame method has now been extended to the strong red and infra-red barium bands.

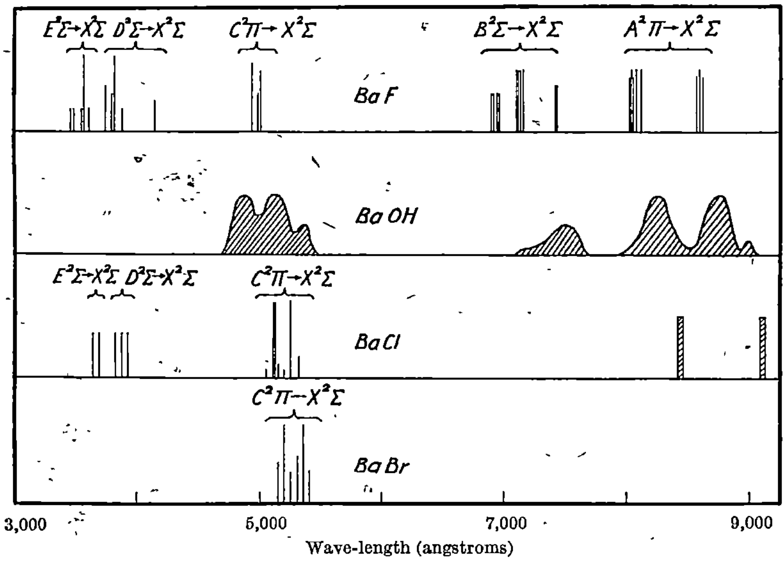

Fig. 1. Diagrammatic spectra of barium halide radicals, compared with the diffuse bands of barium flame spectrum

It has been pointed out by James and Sugden that there is a very marked similarity between the spectra of the alkaline-earth halide radicals and hydroxide radicals, the hydroxide falling between the fluoride and chloride. With calcium and strontium the green and orange and orange and red flame bands correspond to $B^2\Sigma \rightarrow X^2\Sigma$ and $A^2\Pi \rightarrow X^2\Sigma$ systems of the halide radicals. In the case of barium the blue-green bands correspond to the $C^2\Pi \rightarrow X^2\Sigma$ halide system. Bands analogous to the first two systems can be predicted to lie in the red and infra-red, in the region 7000–9000 A. It has been suggested by Huldt and Lagerqvist that barium flame bands lying at 8000–10,000 A. might be due to BaOH.

These bands were photographed, and the spectrum is represented diagrammatically in Fig. 1, together with the spectra of barium halide radicals as listed by Pearse and Gaydon[4]. It extends from about 7200 A. to 9000 A. (and probably beyond). The bands are all broad and diffuse and cannot possibly be confused with the red BaO bands, which show heads and are degraded to the red. The general appearance of these bands is exactly the same as of those in the blue and green, which are known to be due to BaOH. The resemblance between the distribution of the diffuse bands and BaF bands is very marked. It thus seems very probable that all the diffuse bands in the flame spectrum of barium arise from the same molecule, BaOH.

Further evidence was obtained from measurements of the integrated intensities, using a glass spectrometer of low resolution combined with a photoelectric device. The measurements were made in various flames, obtained by burning different mixtures of hydrogen and oxygen, with nitrogen diluent, in a Méker burner. The flames were of the shielded type, described by James and Sugden[5], and barium was introduced into them in the form of a fine spray of a dilute salt solution. The flame temperatures were measured by the sodium D-line reversal method.

In Fig. 2, $\log_{10} I_{\text{band}}$ is plotted against $1/T°$ K. for the red and infra-red bands, the green BaOH band (λ approx. = 5150 A.) being included for comparison. The experimental points do not lie on smooth curves but are grouped into 'families' of four, characterized by different nitrogen-to-oxygen ratios in the pre-burned gases. This effect illustrates the dependence of the concentration of the emitter on the composition of the flame, and it is practically the same for the three bands considered. (The accuracy of the measurements decreases towards lower temperatures.) Very similar results are obtained for the corresponding bands in the spectra of calcium and strontium. In all cases the dependence of band intensity on flame composition is characteristic, and so the red and infra-red BaOH bands fit very well into the general scheme of hydroxide radical bands. It will be recalled that it was on the basis of measurements made on the band intensities in isothermal flames that James and Sugden originally identified the strongest features of the alkaline-earth flame spectra as due to hydroxide radicals.

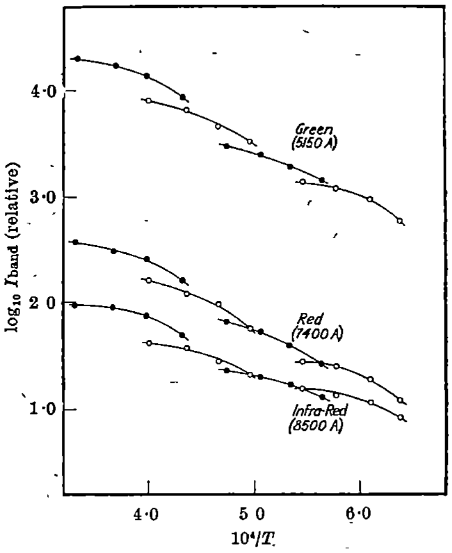

Fig. 2. Intensities of BaOH bands in various flames

I am grateful to Dr. T. M. Sugden for his advice and encouragement, and to Girton College and the Ministry of Education for a studentship.

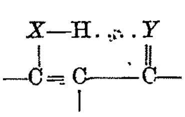
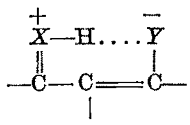
Infra-red Spectra of Chelating Agents: 2-Phenacylpyridine Derivatives

It has been suggested that in a conjugated system of the type (I), where XH and Y can form a hydrogen bond donor–acceptor system, there is a significant contribution of the ionic form (II) to the ground state of the chelate system.



(I)



(II)

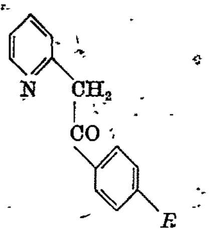
This phenomenon has been termed 'conjugate chelation', and has been observed to occur in acetylacetone, enolizable cyclic β-keto esters, in partially fluorinated β-diketones, in 2-acetyl-1-hydroxy naphthalene and related compounds, in 1-hydroxy anthraquinones, in flavanones and in ortho hydroxy aromatic aldehydes and ketones. All these compounds belong to the type (I) where X and Y represent oxygen atoms, but they fall into two classes. On one hand, there are the aliphatic and alicyclic materials, in which the double bond plays no part in any resonant system other than the chelate ring; and on the other hand are the aromatic compounds where the enol double bond is involved in an additional resonant system.

The systems mentioned above are characterized by carbonyl absorptions which are of increased intensity and widely shifted from the normal position. Furthermore, the hydroxyl absorptions are weak and diffuse, and so greatly shifted from the normal position as to indicate extremely strong hydrogen bonding.

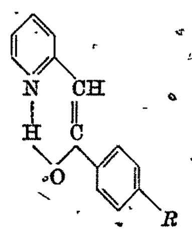
As part of a general investigation into the infra-red spectra of chelating agents and metal chelates, some derivatives of 2-phenacylpyridines[1] have been examined. These compounds, which are of interest because of their possible bacteriostatic activity[2], are now shown to represent another class exhibiting conjugate chelation.

All the compounds were examined as solid mulls in 'Nujol' and as solutions in chloroform, carbon tetrachloride or bromoform. The spectra were obtained with a Perkin–Elmer double-beam automatic recording spectrophotometer with a rock-salt prism.

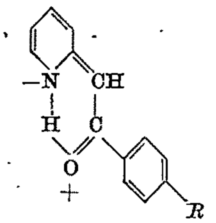
The infra-red spectrum of 2-phenacylpyridine (III, R = H) in the solid state does not show an absorption in the position normal for a carbonyl which is conjugated with an aromatic ring (1,700–1,680 cm.$^{-1}$)[3], and neither can any hydroxyl absorption be observed. In chloroform or carbon tetrachloride solution, however, where an equilibrium between the keto and enol forms exists, a very weak, diffuse hydroxyl absorption can be observed in the anomalous position of 2,600 cm.$^{-1}$. It can be concluded, therefore, that not only does 2-phenacylpyridine exist, in the solid state, in the enol form (IV, R = H), but also that the intramolecular hydrogen bond is greatly strengthened by resonance stabilization with the ionic forms (V, R = H and VI, R = H) (cf. resonance stabilization of carboxylic acid dimers, C. A. Coulson, "Valence", p. 303).



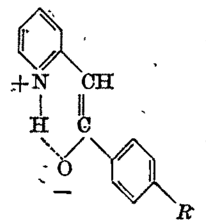
(III)



(IV)



(V)



(VI)

Similar results were obtained from a series of 2-phenacylpyridine derivatives (see Table 1), with the exception of the hydroxy- and amino-compounds, which show a normal carbonyl absorption, and exist in the keto form in the solid state. It is significant that the hydroxy- and amino-groups have the largest negative Hammett σ values of the various substituents in Table 1, but it should also be noted that these two groups offer alternative hydrogen donors for hydrogen-bond formation.

The compounds listed in Table 1 show only two bands in the out-of-plane C—H deformation vibration region, and these can be assigned to the pyridine ring substituted in the α-position and the para di-substituted benzene ring. In each of the compounds which exists in the enol form (and where conjugate chelation occurs), the benzene and pyridine ring absorptions are constant, but situated at the extremes of the normal ranges. In the hydroxy- and amino-compounds, however, the frequencies are not constant, but appear in expected positions. Furthermore, both the benzene- and pyridine-ring absorption bands appear as doublets, or undergo considerable shifts,[4] when these compounds are examined in

Table 1. OUT-OF-PLANE C—H DEFORMATION FREQUENCIES OF 2-PHENACYLPYRIDINE DERIVATIVES

Compound	Hammett σ value of substituent*	Pyridine ring vibration frequency (cm.$^{-1}$)	Benzene ring vibration frequency (cm.$^{-1}$)
2-*p*-Bromophenacylpyridine	+ 0·232	741	800
2-*p*-Chlorophenacylpyridine	+ 0·227	741	800
2-*p*-Fluorophenacylpyridine	+ 0·062	738	803
2-*p*-Methylphenacylpyridine	− 0·17	741	800
2-*p*-Methoxyphenacylpyridine	− 0·268	738	803
2-*p*-Hydroxyphenacylpyridine	− 0·357	756	822
2-*p*-Aminophenacylpyridine	− 0·660	763	833

* Jaffe, *Chem. Rev.*, 53, 191 (1953).

bromoform solution in which both the keto- and enol-forms exist. (Bromoform is transparent in this region.) There is normally very little difference between the spectra of the solid and the solution for these particular frequencies.

This observation is of interest in view of the attention currently being given to the relation between polarity and infra-red frequencies[4]. These results also indicate that it may be possible to study keto–enol tautomerism in these cases in the low-frequency region which possesses the advantages of being fairly clear and containing strong bands.

Further work on these compounds will be published later. Thanks are due to Drs. A. H. Beckett and K. A. Kerridge, of the School of Pharmacy, Chelsea Polytechnic, for providing the samples.

Photoelectric Phenomena with Copper Phthalocyanine

On the evidence of the dependence of electric conductivity upon temperature, Eley[1] and Vartanyan[2] reached the same conclusion, namely, that both phthalocyanine and its metallic derivatives should be regarded as kinds of semiconductors. In this connexion we wish to report that copper phthalocyanine exhibits the following photoelectric phenomena: (1) photoconductivity, (2) generation of electromotive force, and (3) change of the surface potential, both (2) and (3) being induced by illumination.

Experiments were conducted *in vacuo* at room temperature, employing crystal films prepared by vacuum sublimation. The light sources were a tungsten filament lamp, and mercury and sodium vapour lamps. Suitable filters being employed, whenever necessary, it was ascertained that the photoelectric phenomena occurred upon the illumination with ultra-violet or near infra-red as well as with visible light.

Conductance was measured by means of a surface cell. The organic crystal was deposited by sublimation on the surface of a quartz plate between the two gold electrodes of the cell. Photocurrents obey Ohm's law within the range studied (up to 100 V./cm.), and are proportional to the square roots of the light intensities.

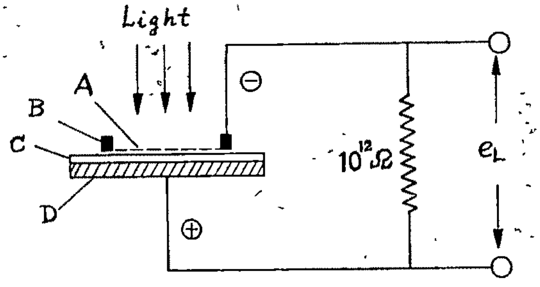

Fig. 1. Photocell for the measurement of electromotive force. *A*, translucent gold film; *B*, metallic ring; *C*, specimen film; *D*, platinum disk

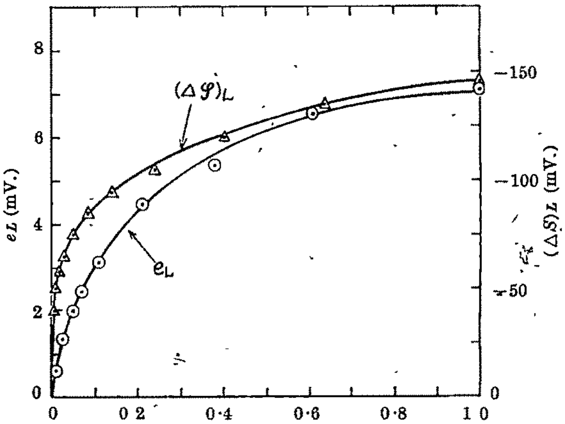

Fig. 2. The terminal voltage e_L and the change of surface potential $(\Delta S)_L$ plotted against light intensity (tungsten filament lamp

The cell used in measuring the electromotive force was of the sandwich type; that is, the crystal to be tested was first deposited on the surface of a platinum disk and then a thin translucent film of gold was prepared by evaporation upon the organic crystal (Fig. 1). When the photocell was illuminated without imposing any external voltage, an electromotive force was generated, and the film of gold became negative. In Fig. 2 the terminal voltage e_L induced by the illumination is plotted against the light intensity.

The surface potential was measured with a vibrating capacity electrometer. The fixed electrode was a platinum disk covered with the organic film. There occurred a distinct change upon illumination in the surface potential of the crystal film. The photoelectric effect of this experiment was of the same nature as found in the usual inorganic semiconductors such as germanium[3] and in organic dyes such as crystal violet[4]. The relation between the change of surface potential (ΔS_L) and the light intensity is also shown in Fig. 2.

These photoelectric phenomena are possibly due to the creation of mobile charges (electrons or positive holes) by the illumination, so that they should all be related to one another. They are certainly evidence of the semiconducting character of copper phthalocyanine. Similar phenomena have also been observed in our laboratory in crystals of metal-free phthalocyanine.

Details of the work described above will be published elsewhere. We thank Prof. K. Higasi for his interest and encouragement.

FORTHCOMING EVENTS

Monday, April 9—Tuesday, April 10

Society of Chemical Industry, London Section (in the William Beveridge Hall, Senate House, University of London, London, W.C.1), at 9.30 a.m. daily—Symposium on "Applications of Infrared Spectroscopy".

Monday, April 9—Saturday, April 14

Institution of Electrical Engineers (at Savoy Place, London, W.C.2)—Convention on "Digital-Computer Techniques".

Tuesday, April 10

Zoological Society of London (at the Zoological Gardens, Regent's Park, London, N.W.1), at 5 p.m.—Scientific Papers.

Institution of Chemical Engineers (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. H. I. Downes: "Patents in Chemical Engineering".

Society for Analytical Chemistry, Physical Methods Group (in the Large Chemistry Lecture Theatre of the Imperial College of Science and Technology, South Kensington, London, S.W.7), at 6.30 p.m.—Meeting on "Plant Instrumentation". Dr. B. W. Bradford: "Progress in Plant Analytical Control Methods"; Dr. A. E. Martin: "The Sonic Gas Analyser"; Mr. D. A. Patient: "Automation in the Laboratory".

Tuesday, April 10—Thursday, April 12

Faraday Society (in the Great Hall, The University, Nottingham)—General Discussion on "Membrane Phenomena".

Tuesday, April 10—Friday, April 13

Institute of Metals (in London)—Spring Meeting.

Tuesday, April 10

(At the Royal Institution, Albemarle Street, London, W.1), at 7 p.m.—Dr. Willis Jackson, F.R.S.: "Ferroelectrics—the Dielectric Analogue of Ferromagnetics" (May Lecture).

Wednesday, April 11

(At Church House, Great Smith Street, S.W.1), at 10 a.m.—Annual General Meeting. Major C. J. P. Ball: "The History of Magnesium" (Presidential address).

Wednesday, April 11

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. Raymond Pickering: "The Pleistocene Geology of the South Birmingham Area". (Paper to be read by Prof. F. W. Shotton.)

Royal Meteorological Society (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Mr. J. Paton: "The Polar Aurora" (Symons Memorial Lecture).

Institute of Petroleum (at 26 Portland Place, London, W.1), at 5.30 p.m.—Mr. J. W. Platt: "The Oil Industry—Its Place in the World and Its Future".

Society of Chemical Industry, Food Group—Nutrition Panel (at the Royal Society of Medicine, 1 Wimpole Street, London W.1), at 5.45 p.m.—Annual General Meeting; at 6 p.m.—Fourth and Final meeting of the series "Nutritional Requirements and Food Fortification".

Society for Analytical Chemistry, Microchemistry Group (in the Restaurant Room of "The Feathers", Tudor Street, London, E.C.4), at 6.30 p.m.—Discussion meeting on "Complexones in Microchemistry". Opening Speakers: Mr. H. J. Cluley and Mr. C. Whalley.

Wednesday, April 11—Thursday, April 12

Laboratory Animals Bureau (at the Royal Veterinary College, Royal College Street, London, N.W.1), at 9.30 a.m. daily—Ninth Congress.

Wednesday, April 11—Friday, April 13

Society of Chemical Industry, Plastics and Polymer Group (in the William Beveridge Hall, Senate House, University of London, London, W.C.1), at 10 a.m. daily—Symposium on "Epoxide Resins—Their Chemistry and Structure in Relation to Their Properties and Applications".

Thursday, April 12

Royal Society of Arts, Commonwealth Section (at John Adam Street, Adelphi, London, W.C.2), at 5.15 p.m.—Mr. H. Nutcombe Hume: "The Work of the Colonial Development Corporation" (Thomas Holland Memorial Lecture).

Institution of Chemical Engineers (in the Lecture Theatre, Institution of Civil Engineers, Great George Street, London, S.W.1), at 5.30 p.m.—Mr. W. L. Wilson, Mr. P. A. White and Mr. J. G. Milton: "The Control, Conveyance, Treatment and Disposal of Radioactive Effluents".

Physical Society, Acoustics Group (at the Imperial College, Imperial Institute Road, London, S.W.7), at 5.30 p.m.—Mr. A. Poliakoff: "Development of Transistor Hearing-Aids".

Society of Chemical Industry, Microbiology Group (at the Medical Society of London, 11 Chandos Street, Cavendish Square, London, W.1), at 6 p.m.—Annual General Meeting. Mr. H. J. Bunker: "Microbiology in Industry".

British Psychological Society (joint meeting of the Industrial and Social Psychology Sections, in the Psychology Department, Birkbeck College, Malet Street, London, W.C.1), at 7.30 p.m.—Prof. Ross Stagner (University of Illinois): "Recent Psychological Research in Industrial Relations".

Thursday, April 12—Friday, April 13

Institute of Physics, X-Ray Analysis Group (joint meeting with the Low Temperature Group of the Physical Society, at the Clarendon Laboratory, Oxford)—Conference on "Low Temperature Crystallography".

Society of Leather Trades' Chemists (in the Chemistry School, Pembroke Street, Cambridge), at 9.30 a.m. daily.—Symposium on "Vegetable Tannins".

Friday, April 13

Laboratory Animals Bureau (at the Royal Veterinary College, Royal College Street, London, N.W.1), at 9.45 a.m.—Symposium on "Infections of Laboratory Animals". Chairman: Prof. J. W. Howie.

Biochemical Society (in the Department of Biochemistry, The University, Glasgow), at 11.30 a.m.—Scientific Papers.

Institute of Metals (in the Weir Hall of the Institution of Naval Architects, 10 Upper Belgrave Street, London, S.W.1), at 2.30 p.m.—Prof. Erich Schmid (University of Vienna): "Electron Emission from Metals".

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Scientific Meeting.

Institution of Mechanical Engineers, Applied Mechanics Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 5.30 p.m.—Prof. J. L. M. Morrison, Mr. B. Crossland and Mr. J. S. C. Parry: "Fatigue Under Triaxial Stress—Development of a Testing Machine and Preliminary Results"; Mr. N. E. Frost and Mr. C. E. Phillips: "The Fatigue Strength of Specimens Containing Cracks".

Institute of Physics, Industrial Spectroscopy Group (at 47 Belgrave Square, London, S.W.1), at 5.30 p.m.—Mr. F. W. J. Garton: "Determination of Isotopic Abundance by Emission Spectroscopy".

Aslib (at the Royal Society of Arts, 8 John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Mr. C. N. Kington: "Industrial Research for Small Firms, with special reference to the Role of Information Services".

Friday, April 13—Sunday, April 15

Botanical Society of the British Isles (in Tuke Hall, Bedford College, Regent's Park, London, N.W.1), at 10.15 a.m. daily—Conference on "Progress in the Study of the British Flora".

Sunday, April 15

Field Meeting in the neighbourhood of Hitchin, Hertfordshire.

Saturday, April 14

Association of Clinical Biochemists (joint meeting with the Biochemical Society, in the Biochemistry Department, The University, Glasgow)—Papers and Demonstrations, including a Symposium on "Clinical Control of Electrolyte Deficiencies".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant (Grade A) in the Electrical Engineering and Physics Department, primarily for physics, calculations and engineering science—The Secretary, Poplar Technical College, Poplar High Street, London, E.14 (April 14).

Assistant Lecturer or Lecturer (with special qualifications in applied mathematics or theoretical physics) in the Department of Applied Mathematics—The Registrar, University College of Wales, Aberystwyth (April 14).

Assistant Lecturer or Lecturer (with special qualifications in either inorganic or physical chemistry) in the Department of Inorganic and Physical Chemistry—The Registrar, The University, Liverpool (April 14).

Chemist (honours graduate, preferably with experience of spectrochemical equipment) for advisory work concerned mainly with trace elements in plant nutrition—The Secretary, Edinburgh and East of Scotland College of Agriculture, 13 George Square, Edinburgh (April 14).

Director (scientist or technologist of established reputation, with administrative experience) of the Science Museum—The Secretary, Civil Service Commission, Scientific Branch, 30 Old Burlington Street, London, W.1, quoting S.4575/56/1 (April 14).

Assistant Lecturer (preferably female) in Physics—The Principal, Royal Holloway College, Englefield Green, Surrey (April 16).

Lecturer or Assistant in the Joint Department of Chemical Technology and Chemical Engineering (University of Edinburgh and Heriot-Watt College)—The Assistant Secretary, The University, Edinburgh (April 16).

Scientific Officer, Grade 3 (with a degree of high standard, with physics as a major subject, together with several years relevant research experience) in the Defence Standards Laboratories, Department of Supply, Maribyrnong, Victoria, Australia, for research in X-ray and gamma-ray physics—The Senior Representative (AP.58), Department of Supply, Australia House, Strand, London, W.C.2 (April 16).

Forestry Officer (with a degree in forestry from a British university) for work on schemes for the planting of derelict pit heaps, tree preservation orders, felling licences, park layout, etc.—The County Planning Officer, 10 Church Street, Durham (April 18).

Lecturer (with a good honours degree) in Chemical Engineering—The Registrar, King's College, Strand, London, W.C.2 (April 18)

Assistant Lecturer in Biology—The Registrar, University College of North Staffordshire, Keele, Staffs (April 20).

Chemist (with an honours degree in chemistry or equivalent qualifications, and at least two years industrial experience) in the Technical Policy Branch of the Industrial Group of the United Kingdom Atomic Energy Authority, to assist in the preparation of long-term programmes covering all activities of the Industrial Group—The Recruitment Officer, U.K.A.E, Industrial Group. Headquarters, Risley, near Warrington (April 20).

Engineers and Physicists (Experimental Officer grade) in the Rocket Propulsion Department, Ministry of Supply, Westcott, Bucks, for research and development on rocket motors and propellants; instrumentation and recordings; investigations on high speed flow and heat transfer problems—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.105/6A/BN (April 21).

Assistant Lecturer in Applied Mathematics—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (April 25).

Senior Lecturers, Lecturers or Assistant Lecturers in Botany, Organic Chemistry, Mathematics and Zoology, at the University College of Khartoum, Sudan—The Secretary, Inter-university Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (April 25).

Assistant Lecturers (Grade III) or Demonstrators (2) in Physiology—The Registrar and Secretary, The University, Bristol (April 27).

Aerodynamicist or Mathematician (with a first- or second-class honours degree or equivalent in engineering or mathematics, and preferably with experience in experimental aerodynamics), at the Ministry of Supply Royal Aircraft Establishment, Bedford, to work in a section responsible for full-scale aerodynamics research on helicopters—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.110/6A (April 28).

Assistant (with an honours degree in physics) in the Department of Natural Philosophy—The Assistant Secretary, The University, Edinburgh (April 28).

Lecturer (with special qualifications in mineralogy, including a working knowledge of X-ray techniques) in the Department of Geology—The Registrar, The University, Bristol (April 28)

Imperial Chemical Industries Research Fellows in Biochemistry, Chemistry, Chemotherapy, Engineering, Metallurgy, Pharmacology, Physics, and subjects allied to chemistry and physics—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 30).

Lecturer, Grade III or Grade II (preferably with research interests in the field of high energy physics and theories of elementary particles), in the Department of Physics—The Registrar, The University, Bristol (April 30).

Lecturer or Assistant Lecturer in Philosophy at the University of Malaya, Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (April 30).

Lecturers or Assistant Lecturers in Botany and Zoology, at the University of Malaya, Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (April 30).

Senior Lecturer (with a good honours degree, and preferably with experience in teaching overseas students) in Geography, at Fourah Bay College, Sierra Leone (University of Durham)—The Secretary, Advisory Committee on Colonial Colleges, 1 Woburn Square, London, W.C.1 (April 30)

Chair of Botany at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong, May 7).

Lawrence Hargrave Chair of Aeronautical Engineering at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, May 7).

Reader in Mechanical Engineering at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong, May 7).

Lecturer or Assistant Lecturer in Organic Chemistry—The Registrar, The University, Leeds 2 (May 12)

Assistant Lecturer in Inorganic or Physical Chemistry—The Secretary, Queen's University, Belfast (May 15).

Research Assistant (with a degree of doctor of philosophy or equivalent research experience) to work in the Department of Applied Mathematics on quantum collision problems.—Prof D. R. Bates, Queen's University, Belfast (May 15).

Lecturer (with a university degree in forestry and additional training and experience in forest zoology, or an honours degree in entomology (or zoology including entomology)) in Forest Zoology—The Assistant Secretary, The University, Edinburgh (May 31)

Scientific Assistant (with an honours degree in biological sciences, some knowledge of foreign languages and the ability to write correct English)—The Director, Commonwealth Bureau of Plant Breeding and Genetics, School of Agriculture, Cambridge (June 1).

Leverhulme Student for research in Chemical Engineering—The Registrar, Imperial College, London, S.W.7 (July 1).

Instructors (with a Ph.D. degree or equivalent) in the Department of Chemistry, for duties which will involve undergraduate lecturing in Inorganic, Analytical and Physical Chemistry, and laboratory demonstrating—Prof. C. A. McDowell, Department of Chemistry, University of British Columbia, Vancouver 8, B.C., Canada.

Laboratory Technician (with some chemical experience)—Prof. F. C. Happold, Department of Biochemistry (University of Leeds 9 Hyde Terrace, Leeds 2.

Master to take Physics up to University Entrance standard—The Headmaster, Keswick School, School House, Keswick, Cumberland.

Research Assistant (Ph.D. standard) for work on the physical absorption of vapours on ionic crystals—Dr. F. C. Tompkins, F.R.S., Imperial College, London, S.W.7.

Technician (preferably with photographic and radiation experience) in the Physics Department, to assist in a radiation protection service—The Secretary, Institute of Cancer Research, Royal Cancer Hospital, Fulham Road, London, S.W.3.

New Books

Soil Zoology

Edited by D. K. McE. Kevan, B.Sc., A.I.C.T.A., *University of Nottingham.*

This book contains the papers read at the Second Easter School in Agricultural Science organized by the University of Nottingham School of Agriculture, together with a full account of the techniques demonstrated. The purpose of the school was to provide a forum for discussion among specialists in soil zoology and to provide tuition, both theoretical and practical, for those who are now working in the field but who have hitherto received no specialist training. Price 55s.

Combustion Instability in Liquid Propellant Rocket Motors

By Luigi Crocco and Sin-I Cheng, *Daniel and Florence Guggenheim Jet Propulsion Centre, Princeton University.*

The results of combustion roughness on the operation of a rocket can produce very detrimental effects such as severe vibration and interference with the controls, mechanical failure, or burn-out of the internal walls. The importance of these detrimental effects makes it necessary to gain some understanding of the underlying processes.

The present monograph approaches the problem by making use of our present knowledge of combustion processes. The first part discusses a rational explanation for the existence of rough combustion on a qualitative basis. The second part distinguishes a number of mechanisms which may be responsible for severe roughness. The third part establishes a quantitative relationship for the theoretical treatment of these mechanisms, and a final section is devoted to the development of the theory and discussion of results. Price 37*s.* 6*d.*

SESSION 1956-1957 BEGINS MONDAY
OCTOBER 1, 1956

Part-time (Evening) Courses provided for Internal Degrees in the Faculties of Arts and Science and for the Academic Postgraduate Diploma in Psychology. Facilities also provided for part-time and full-time students reading for higher degrees in arts and science. Applications for admission should be made before June 1.

Pamphlet and form of application may be obtained from the Registrar, Birkbeck College, Malet Street, W.C.1.

BOROUGH POLYTECHNIC

BOROUGH ROAD, S E 1
(Revised Announcement)
CHEMICAL REACTIONS INDUCED BY IONIZING RADIATIONS

A course of four lectures to be given by Dr A. J. Swallow, on Wednesdays, 6 30 to 8.30 p m, April 11, 18, 25 and May 2 Fee for the course is 10s.

For syllabus and further details, apply to the Secretary at the Borough Polytechnic.

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

The following courses of lectures will be given in the Department of Chemical Engineering on Monday afternoons, commencing April 30, 1956 "Flame Spectroscopy." Six lectures by Dr. A. G. Gaydon at 2.30 p.m "Optics of Flames." Seven lectures by Dr. F J. Weinberg at 4 p.m.

For details, apply to the Deputy Registrar, City and Guilds College, London, S.W 7

OFFICIAL APPOINTMENTS

The engagement of persons answering these advertisements must be made through a Local Office of the Ministry of Labour or a Scheduled Employment Agency if the applicant is a man aged 18 to 64 inclusive, or a woman aged 18 to 59 inclusive, unless he or she, or the employment, is excepted from the provisions of the Notification of Vacancies Order, 1952.

ANIMAL HEALTH TRUST

WELLCOME VETERINARY RESEARCH FELLOWSHIPS

Applications are invited for the appointment of one or more Wellcome Fellows, for whole-time research in connection with veterinary science or medicine, from any person who on October 1, 1956, is under 36 years of age and holds the Membership Diploma of the Royal College of Veterinary Surgeons or a degree in any faculty relevant to veterinary science or medicine in any university in the British Commonwealth and Empire. Applicants are expected to have done some postgraduate work. One or more Fellowships may be awarded at an annual value of £850, rising by annual increments of £50. The Fellowship is subject to income tax and carries benefits under the F.S S U.: it is tenable for one year in the first instance and by annual reappointment for a further period of two years at the discretion of the Advisory Committee Election will be made in June, to take effect as from October 1, 1956 Closing date for receipt of applications, Monday, May 14, 1956.

Forms of application are obtainable from: The Scientific Director, The Animal Health Trust, 14 Ashley Place, Westminster, London, S W.1.

UNIVERSITY OF BRITISH COLUMBIA

DEPARTMENT OF CHEMISTRY

Applications are invited for several posts as Instructors Duties will involve undergraduate lecturing in Inorganic, Analytical, and Physical Chemistry, and laboratory demonstrating Candidates should have a Ph D. degree or its equivalent. Successful applicants will be expected to pursue research work in one of the following fields: catalysis, mass spectrometry, combustion kinetics, electron transfer processes, high resolution nuclear magnetic resonance, paramagnetic resonance spectra of free radicals, or molecular structure.

Applications, which should include the names and addresses of two referees, should be sent immediately to Professor C. A. McDowell, Department of Chemistry, University of British Columbia, Vancouver, 8, B C, Canada

COLLEGE OF ARTS AND SCIENCE

BAGHDAD, IRAQ

Applications are invited for the following positions: (1) Lecturer in Geology, specializing in palaeontology-stratigraphy. (2) Lecturer in Geology, specializing in petrology-mineralogy Salary scale: I D. 1,600 to I.D. 1,800 per annum, depending upon qualifications; plus cost of living allowance ranging from I.D. 120 to I.D 168 per annum. The Government contributes 10 per cent and the lecturer 5 per cent of his salary to the provident fund. The Iraq Government offers a contract for one year in the first instance, renewable by mutual agreement annually. The lecturer's fares will be paid at the beginning and end of the contractual period, as well as those of his wife and up to two children. The selected candidate will be expected to assume his duties in Baghdad not later than September 30, 1956

Further information may be obtained from the Acting Dean. Applications should be sent by air mail.

ROYAL TECHNICAL COLLEGE

GLASGOW
(Affiliated to the University of Glasgow)
DEPARTMENT OF MECHANICAL, CIVIL, AND CHEMICAL ENGINEERING
CHAIR OF CIVIL ENGINEERING

The Governors of the Royal Technical College invite applications for the Chair of Civil Engineering, tenable in the Department of Mechanical, Civil, and Chemical Engineering. The salary attached to the Chair is £1,900 by £100 to £2,200.

Particulars of the appointment and forms of application may be obtained from the Secretary-Treasurer, George Street, Glasgow, C.1.

UNIVERSITY OF GLASGOW

ASSISTANTSHIP IN MATHEMATICS

Applications are invited for an Assistantship in Mathematics Salary scale: £550 to £650 Initial salary according to experience and qualifications. F.S S U and family allowance benefits

Applications (three copies), should be lodged, not later than April 30, 1956, with the undersigned, from whom further particulars may be obtained.

ROBT. T. HUTCHESON,
Secretary of University Court

BIOCHEMIST

Applications are invited for a position as Biochemist to study nutrition and metabolism of marine bacteria and various problems concerned with the biochemistry of fish. Knowledge of manometric and tracer techniques is desirable, and a Ph.D. or its equivalent from a recognized university is required.

Send details regarding training, publications, references and salary required to the Acting Director, Fisheries Research Board of Canada, Technological Station, Vancouver, 2, B C

THE SIR FREDERICK SMITH AND MISS ALEEN CUST RESEARCH FELLOWSHIPS OF THE ROYAL COLLEGE OF VETERINARY SURGEONS

Applications are invited for a Fellowship of the value of £600 per annum to be used to enable the holder to pursue research or to prepare for such research in any branch of veterinary science. Candidates, who need not be veterinary surgeons, will normally be required to have obtained some postgraduate experience, but this is not essential. The Fellowship is tenable for a maximum period of three years.

Forms of application and copies of the regulations may be obtained from the Registrar, The Royal College of Veterinary Surgeons, 9 Red Lion Square, London, W.C.1, to whom completed forms should be returned by May 15, 1956

UNIVERSITY OF LONDON, KING'S COLLEGE, will require on October 1, 1956, a Lecturer in Chemical Engineering Applicants should have a good honours degree Salary on the scale £700 by £50 to £1,000: £1,050 by £50 to £1,400, with family allowances and superannuation benefits, with starting point according to qualifications and experience.—Applicants should write for conditions of appointment and application forms to the Registrar, King's College, Strand, W.C 2, whom completed applications must reach by April 18

UNIVERSITY COLLEGE OF NORTH STAFFORDSHIRE

Applications are invited for the post of Assi ant-Lecturer in Biology, the appointment to da from October 1, 1956. Candidates should ha general honours degree in biological sciences a preferably have some experience in parasitolog Salary in the scale £600 by £25 to £650 per annu with F.S.S.U. and children's allowances.

Applications should reach the Registrar, T College, Keele, Staffs, from whom further pa ticulars and application forms may be obtaine not later than April 20, 1956.

UNIVERSITY OF ABERDEEN

SENIOR RESEARCH FELLOWSHIP IN DEPARTMENT OF BIOLOGICAL CHEMISTRY
(*Repeated Advertisement*)

Applications are invited for a Senior Resear Fellowship. The Fellow should have an honou B Sc degree in chemistry or biochemistry and r search experience, and would work in the Depa ment of Biological Chemistry on the chemic aspects of a research programme concerned wi the fluorescent labelling of proteins, carried o jointly by the Departments of Pathology, Bacte ology, and Biological Chemistry. Salary with range £700 to £800 according to qualifications a experience. Superannuation (F S.S.U) and chi allowance. Appointment for one year, renewab for two further years

Applications (four copies), including the nam of two referees, should be sent not later th April 16, 1956, to the Secretary, The Universi Aberdeen, from whom further information m be obtained.

NATIONAL RESEARCH COUNCI OF CANADA

Physical Chemist to assist in study of biologic macromolecules at the Atlantic Regional Labor tory in Halifax, Nova Scotia Qualification Ph.D or equivalent with experience in releva modern techniques, i.e, ultracentrifuge, lig scattering, etc Salary will depend on extent experience but the minimum will be $5,500 p annum Canadian Government pension plan, i surance, three weeks' annual leave and thre weeks' cumulative sick leave are applicable, a voluntary group medical and hospitalization pl available

Applications and enquiries to be addressed the Director, Atlantic Regional Laborator National Research Council, Halifax, Canada

UNIVERSITY OF GLASGOW

RESEARCH FELLOWSHIP IN MATHEMATICS

Applications are invited for a Research Fello ship in Mathematics Salary scale: £550 to £65 Initial salary according to experience and quali cations F S.S.U. and family allowance benefit

Applications (three copies), should be lodge not later than April 30, 1956, with the unde signed from whom further particulars may be o tained.

ROBT T. HUTCHESON,
Secretary of University Cour

UNIVERSITY OF BELFAST

The Senate of the Queen's University of Belfa invites applications for a Lectureship in Inorgan Chemistry from October 1, 1956 Salary £650 b £50 to £1,000 and on certain conditions bei fulfilled, to £1,350 plus contributory pension ri under the F S S U Initial placing on the sc £650 to £1,000 depends on experience an qualifications. Applications should be received by May 15, 1956.

Further particulars may be obtained from G F Cowie, M A., LL.B Secretary

ENGINEER OR PHYSICIST REQUIRE at Ministry of Supply, London H Q to co ordinate development work on high precisio electromechanical and electronic control instru ments and systems for guided weapons unde taken by Government Establishments and industry Candidates should possess a first- or second-cla honours degree or equivalent in physics or engi eering Experience appropriate to above duti required and knowledge of modern computin methods an advantage Appointment accordi to age, experience, etc, as Senior Scientific Offic (minimum age 26 with at least three years pos graduate research experience) or Scientific Offic (minimum age 21) Salary within ranges Seni Scientific Officer £1,070 to £1,245; Scientif Officer £513 10s to £925 (superannuable).—Appl cation forms from Ministry of Labour an National Service, Technical and Scientific Regi ter (K), 26 King Street, London, S.W 1, quoti A 113/6A.

When lighting is limited...

When available light is limited the laboratory worker will appreciate the extreme speed* of the new Kodak film, 'Tri-X'.

This speed has been achieved without corresponding increase in grain size. 'Tri-X' is therefore equally suitable for macrography and microscopy, for photography of living specimens and for recording work with very fast light-spots.

Colour sensitivity is evenly balanced throughout the spectrum; exposure latitude is generous. 'Tri-X' adds greatly to the scope of the camera in laboratory work. It is available in 35mm. miniature, 120 and 620 sizes.

Kodak
'TRI-X' FILM

EXPOSURE INDICES:
daylight 34° . . . 200
tungsten 33° . . . 160

**At an exposure of 1/25th sec., and with normal development, only about 0.0015 mcs. exposure is required to give a density of 0.1 above fog.*

We have prepared a folder of data sheets giving information about 'Kodak' films of particular interest to laboratory workers. Please write for your copy.

THE BALANCE OF TECHNOLOGICAL AND TECHNICAL MAN-POWER

THE need for balancing the claims of defence research against the competing claims on Britain's limited resources of man-power, as well as the way in which the size of the Armed Services themselves inevitably affects the man-power available for industry in general, is well brought out in the White Paper on Defence (see *Nature*, April 7, p. 635). The decision to reduce the man-power in the Forces to about seven hundred thousand by March 1958, as announced last October, is intended to provide some relief to the man-power situation as well as to the national economy. While, however, the numerical demand for man-power by the Services may be thus slightly reduced, the premium on skilled man-power, particularly the highly skilled long-service regular service-man, is increased. The improvements in pay in the Armed Services which have recently been announced are intended to increase the numbers of men signing on for, or converting to, long-service engagements and to reduce the wastage of man-power that is unavoidable with a rapid turnover of short-time regulars.

In this respect the Government has thus made a direct attempt to secure the more effective utilization of the man-power of Britain, and particularly skilled man-power; but the elimination of waste in this field has by no means received the attention which it demands. Indeed, the emphasis now being placed on the expansion of technical and technological education sometimes obscures the truth that such measures—even if there were no shortages of science or technical teachers, of buildings or equipment to cause delay in implementing plans—take a term of years to fructify. There are no short cuts or quick returns in educational development; and apart from relieving a particular shortage by measures which merely drain the supply from other demands and create or intensify other shortages, the real hope for the short-term alleviation of the man-power situation lies in the more effective use of the resources already at our disposal.

Some of those possibilities were well indicated in the proceedings of a Conference on the Utilization of Scientific Professional Manpower held at Columbia University, New York, in October 1953, and which have since been published[*]. The report appears to have received little notice in Britain, although it indicates questions to which answers are urgently required in Britain if man-power resources are to be wisely handled, and indeed if the resources now to be devoted to technical and technological education are to be expended to the best advantage, from the point of view of the nation and from that of the students themselves. For example, the recent White Paper on Technical Education assumes that five or six technicians may be required for each technologist. This, however, is a ratio which will vary from one occupation or profession to another. If we are to take account of it in planning the expansion of technical and technological education, we need to have more accurate information as to this ratio and as to the relative numbers engaged in the different occupations and professions.

Nor is this all. We need to assure ourselves that the ratio of technician to technologist or professional worker is a reasonable one in the circumstances of to-day, and not one determined purely by professional tradition or conditions which are no longer relevant. For its elucidation of this point alone and for its indication of the possibilities in saving the time of the highly skilled professional worker as a result of careful re-examination of practice in medicine, in engineering and in teaching alone, the proceedings of the Columbia University Conference merit consideration by all concerned with the more efficient utilization of scientific and technical man-power in Britain. We cannot afford to allow questions of either professional status or practice to hinder the fuller use of supporting technicians when this can be done without detriment to professional standards and the quality of the service.

This question of the ratio of technicians to technologists thus opens up larger issues. We need to ask the reasons for these ratios, why they should vary from industry to industry, from profession to profession, or even from plant to plant within an industry. The answers to such questions will often throw light on the ways in which the less highly trained workers could be used to support and increase the efficiency of those fully trained, and may indeed suggest new ways in which the existing shortages of scientists and technologists could be ameliorated by making use of those with much less training.

This is only the first of six major approaches to the more effective utilization of scientific and professional man-power suggested at the Conference. Another is that adopted by the British Government in the new schemes of pay for the Armed Services, in so far as these provide incentives to prevent the wasteful turnover of professional trained personnel. This is a field in which industry, by giving more attention to the selection and placing of its recruits, could probably do even more to reduce wastage; but more still will be done if, in the new plans for the expansion of technical and technological education in Britain, due attention is given to encouraging adaptability and adequate breadth of education, as indeed the White Paper recognizes.

Another major approach specified at the Conference was the re-assessment of the appropriateness of the education and training of professional persons; and this point is one that is of especial importance in considering the expansion of technical education in Britain. Even when full account is taken of the importance of encouraging adaptability, the effective utilization of scientific and technical man-power always depends on the way in which professional education and training are related to the functions which those so trained are expected to perform. This is one reason why the syllabuses for professional examinations as well as the curricula of technical colleges and universities require continual re-appraisal in the changing world of to-day. Moreover, if wise decisions are to be made, the conception of the purpose of technological and of technical education, as well as of university education, must be clear and sound.

---

[*] National Manpower Council. Proceedings of a Conference on the Utilization of Scientific and Professional Manpower Held October 7–11, 1953, at Arden House, Harriman Campus of Columbia University. Pp. xii+197. (New York: Columbia University Press, 1954.) 3 dollars 50 cents.

The development of new patterns of work to improve the total output of professional workers and technicians in concert is another major approach which demands fresh minds and constructive thinking, as well as a good deal of investigation. It could well prove a most fruitful field of investigation by the joint committees of the Department of Scientific and Industrial Research and the Medical Research Council, and some of the possibilities in this direction were indicated by the Secretary of State for Air in presenting the Air Estimates on March 5. Another major approach suggested is the increased use of capital to permit the full employment of professional skill. This is an approach which, apart from capital considerations, is clearly more difficult to explore in Britain than in the United States. Under certain conditions, additional expenditure on buildings or equipment may well increase the output of goods or services from the same number of technologists or scientists. It will not, however, be sufficient to secure their co-operation alone: the fear of redundancy must be dispelled from the minds of those who work with them, and unless this is done the capital expenditure may merely increase the cost of the goods or services without any advantage.

The sixth direction in which the Conference at Columbia University looked for the more efficient utilization of scientific and technical man-power was through improved leadership and administration. This aspect, however, in respect of research was discussed even more fully at the ninth annual conference on the administration of research held last September at the Northwestern University Technological Institute, Illinois*. The pattern of organization in the United States differs considerably from that in Britain, and some of the criticism of that pattern which was expressed at the Conference has not the same validity elsewhere. There may, for example, be less risk in Britain that research activities at the universities will be expanded in ways inimical to teaching or the real purposes of a university: sponsored research and ear-marked grants are scrutinized too carefully, and it should not be too difficult, with the existing organization rightly used, to ensure that fundamental research is pursued on a reasonably even front.

The comments on security and freedom of communication are another matter and touch as closely on the effective utilization of trained man-power in Britain as in the United States. In both countries intimate and rapid communication as well as secrecy and caution are needed in pushing back the frontiers of knowledge in other fields besides that of nuclear energy. The practical problem is to provide the necessary minimum of security around the research and development programmes in the military field without hindering the degree of communication vital to the maximum stimulation of inventive thinking and the effective application of results. To over-emphasize security is inconsistent with the effective prosecution of research, and is a continual cause of wasted man-power.

Again, waste of man-power in research easily arises out of administration which lacks full understanding of the outlook and methods of the research worker. The task of the administrator, even in applied research, consists not merely in selecting the problems but also in providing the conditions which are most stimulating for creative work. Criticisms on this point made in the United States by Mr. P. P. Barnard apply more particularly to defence research; but they have their implications for Britain also, and suggest ways in which the efficiency of such research might possibly be increased by securing greater co-operation on the part of industry.

The criticism by business executives of the administration of research in the United States is of particular interest. Expenditure there on research is estimated at some 4,500 million dollars for the year ending June 30, 1956, of which about 2,000 million dollars will be spent by industry and another 1,000 million dollars on government contracts with industry for defence purposes. The magnitude and variety of such contracts have been severely criticized, as well as the widespread invitations to tender and the tendency on the part of some government agencies in the United States to treat research as a commodity. These were all criticized as wasteful of effort, and waste also arises in the administration of contracts, primarily from the lack of understanding already noted, while secrecy can lead to serious duplication of effort by different departments and organizations. Generally it was considered that industrial research is cheaper than that administered by the Government, and this is a factor which suggests that the effort of the central government should be kept to the minimum that security and like considerations suggest.

From the point of view of the efficient utilization of scientific and technical man-power in Britain, if not of other resources, the distribution of research effort should be determined largely by the appropriateness of the projects for the type of institution. Universities, government departments and research institutions, private research institutions and those of the public corporations and of private industry all have their particular or even special competence, advantage of which must be taken if the nation's resources are to be deployed to the best advantage; nor will this need disappear even when educational developments begin to overtake the shortage of scientific and technical man-power. Merely increasing the number of those who receive technical education will not solve this problem of making full use of creative man-power. It will still be essential to apportion those resources of scientific and technological man-power where they are most needed and can be most effective.

---

* Proceedings of the Ninth Annual Conference on the Administration of Research, September 7–9, 1955, Northwestern University Technological Institute, Evanston, Illinois, U.S.A. Pp. 107. (University Series.) (New York: New York University Press, 1956.) 4 dollars.

Much of this question of securing more efficient utilization of scientific and technical man-power consists essentially in the prosaic work of making small adjustments here and there, so as to improve the relations between government departments or between such departments and industry, or those between the administrator and the research worker. The principles laid down by the Atomic Energy Commission of the United States in relation to its research programme deserve, however, to be noted and applied widely at a time when fundamental research is of growing importance to military and economic security alike. The university is still an unmatched source of fundamental knowledge, and progress in research comes most rapidly when the individual scientist is free to follow the dictates of his own scientific curiosity and reasoning, without pressure from those who seek possible practical application of his findings. Moreover, the most significant progress in fundamental research is achieved by a relatively few outstanding individuals. The emphasis on a research programme should accordingly be on the effective support of selected men rather than of institutions, and the universities which produce these men should be supported in programmes that can be integrated properly with their educational function. It should be remembered, too, that the individual scientist is the best judge of what research effort will lead to the most significant progress in fundamental science ; and it should also be recognized that a programme for the expansion of technical and technological education which fails to take due account of all such considerations is very unlikely to yield the maximum return for its expenditure.

THE CHEMISTRY OF CELLULOSE

Cellulose and Cellulose Derivatives

Prepared under the Editorship of Emil Ott, Harold M. Spurlin and Mildred W. Grafflin. Second completely revised and augmented edition. (High Polymers Series: a Series of Monographs on the Chemistry, Physics and Technology of High Polymeric Substances—Vol. 5.) Part 1, pp. xvi+509 ; Part 2, pp. viii+511–1056 ; Part 3, pp. viii+1057–1601.

(New York : Interscience Publishers, Inc. ; London : Interscience Publishers, Ltd., 1954–55.) 12 dollars each part.

KNOWLEDGE of the chemistry of high polymers has grown so rapidly that it is difficult for the student of to-day to realize that only thirty years ago cellulose was generally regarded as a colloid of the micellar aggregate type based on a comparatively simple unit containing at most a few glucose residues. Even the X-ray crystallographic results were interpreted as providing supporting evidence for this view. New ideas on the possibility of a covalent bond structure for large molecules were provided by the pioneering work of Staudinger, and in 1926 Sponsler and Dore suggested a formula for cellulose in which the molecule was represented as a long chain of consecutively linked glucose residues. This particular structure could not be reconciled with the detailed chemistry of cellulose, and the one now generally accepted, which postulates a long unbranched chain of β-1,4′-linked D-glucopyranose residues, was then put forward by Haworth. Detailed interpretations of the X-ray data on the new basis were given by Meyer and Mark, and to some chemists it appeared that the problems of the structural chemistry of cellulose had been solved. Nevertheless, those whose business it was to deal with industrial applications of cellulose remained dissatisfied, feeling that many of the details which gave the substance its special properties were beyond the range of the available chemical and physical methods of investigation.

To some extent subsequent work on the organization of cotton cellulose, wood cellulose and regenerated cellulose into crystalline regions alternating with less highly ordered portions helped to explain the reactivity of the various celluloses. Much also was discovered which helped to explain the distinctive properties of the oxycelluloses and hydrocellulose. But little was known of the organization of the macromolecules in the region between the single chains revealed by chemical investigation and the relatively gross structural features visible under the ordinary microscope. Only recently has a beginning been made in this field by means of electron microscope studies carried out notably by workers of the Swedish school. Evidence of a complex fibrillar structure comprising bundles of individual cellulose molecules is now coming to light, and although it is perhaps too early to say that anything like a complete picture can yet be presented, it is significant that this recent work tends to bring us back again to the idea of a colloid which depends largely on hydrogen bonds for the preservation of its fine structure. Further work on these lines and on the infra-red spectroscopy of cellulose fibres will be awaited with much interest. Many other fundamental and industrially important problems still await solution, including the nature of the association of cellulose, hemicelluloses and lignin as they occur in lignified plant tissues.

In the meantime, however, the reader will find in the three books under review authoritative accounts of the present state of knowledge in these fields of fundamental scientific study. He will find also detailed discussions of all aspects of the technology of cellulose and its derivatives. The formidable task of revising the 1943 edition in the light of the many subsequent discoveries has been most successfully undertaken by the editors and their two dozen collaborators. Despite the number of authors, the various sections of the book are well balanced and the presentation is remarkably even.

The first part is concerned mainly with the fundamental scientific background, with chapters on the occurrence of cellulose, its chemical nature, and the structure of cellulose fibres. It concludes with a section on the nature of the various substances associated with cellulose in Nature, including brief accounts of lignin, the hemicelluloses and the structure of wood. In Part 2 the subjects considered are more industrial in character. They include the large-scale preparation of cellulose, its bleaching and purification and the special treatments employed in the utilization of wood-pulp for paper-making. There is also a chapter composed of several independent sections which deal with the esters, ethers, xanthates and other derivatives of cellulose, with valuable discussions on the chemical reactivity of cellulose and on the degradation of its derivatives.

In the first section of the third part there is a return to fundamental considerations, with authoritative and clear accounts of important physical features such as the solubility of cellulose and its derivatives, the thermodynamic properties of these solutions, the problems arising in the determination of molecular weights of macromolecular substances, theories of viscosity for dilute solutions of long-chain compounds, and a discussion of flow properties, including rheological phenomena. Next there is a section on the mechanical properties of cellulose followed by one on tests for cellulose and a series of appendixes in which are gathered together a whole host of data which will be invaluable to all whose work is in the cellulose field. Only those who have experienced it can appreciate fully the difficulty of finding such facts in the immensely scattered literature.

It will be clear from this account that this work is a book of reference rather than a text-book. Much of its usefulness will depend, therefore, on the quality of the indexing. Two indexes are provided at the end of the third book—an author index of forty-one closely printed pages and a subject index of seventy-four similar pages. Like the rest of the book, these are excellently done, and in so far as I have tested them they have been found to be readily usable, comprehensive and accurate. There is no doubt that this will long be regarded as a standard work on the subject, and the editors, authors and publishers are to be congratulated on the completion of this revised and augmented second edition.

MATHEMATICS FOR CHEMISTRY STUDENTS

Mathematics for the Chemist

Mathematical Analysis for Chemists, Physicists and Chemical Engineers. By Prof. G. J. Kynch. Pp. vii + 356. (London: Butterworths Scientific Publications; New York: Academic Press, Inc., 1955.) 30*s*. net.

PROF. G. J. KYNCH'S book is intended to meet the needs of students taking honours courses in chemistry, to provide a text with emphasis on the applications of mathematics, and to serve as a reference book for practising chemists and biochemists. Although written by a professional mathematician, it aims at being intelligible and useful in its field, and a characteristic is the brief yet reasonably strict nature of the methods used. Many results of integrations are merely stated, but the reader should easily find them by using methods which are explained.

The differential and integral calculus, series, exponential, logarithmic and hyperbolic functions, complex numbers, differential equations, determinants, vectors, Fourier series and spherical harmonics are included. An account of curvilinear co-ordinates and their applications would have been useful and could have taken the place of some of the text on approximate solution of equations and numerical methods. The treatment throughout is clear and interesting, the chapter on series being particularly good, and the book can be strongly recommended. The exercises call for thought rather than use of formulæ, and contain some useful additions to the text. References to books are given at the ends of the chapters. The book may not supply all the needs of users the author has in mind, who will want to know something about contour integrals, matrices and elementary group theory, but it provides a sound basis for future extension of knowledge.

The book is evidently based on teaching experience and a knowledge of the special difficulties of students of chemistry; many matters passed over in purely mathematical books are clearly explained, and cases where errors easily arise are pointed out. It may be suggested, with due deference, that pure mathematicians could with advantage look through the book with reference to their own courses. When the lectures to chemistry students are taken by a junior on the mathematics staff, the book will be of great assistance to him in pointing out the needs of the students and the kind of treatment which is desirable.

NATURE CONSERVATION FOR TEACHERS

Handbook for Teaching of Conservation and Resource-Use

Prepared by the National Conservation Committee of the National Association of Biology Teachers in conjunction with the American Nature Association. (Richard L. Weaver—Project Leader.) Pp. 500. (Danville, Ill.: Interstate Printers and Publishers, Inc., 1955. Obtainable from Project Leader, National Association of Biology Teachers, P.O. Box 2073, Ann Arbor, Mich., U.S.A.) 4 dollars.

A PUBLIC awareness of the importance of wise use and management of natural resources is highly desirable, particularly in view of the ever-growing demands which increasing world population makes upon them. In the United States the National Association of Biology Teachers has aimed at increasing this awareness by its conservation project, seeking to introduce conservation studies into schools wherever possible. The word conservation is here used in its widest sense—virtually an attitude of mind towards natural resources, akin to that of the ecologist regarding mankind as a biotic factor in the general scheme of Nature.

This book, which has been prepared for teachers, describes all possible methods of teaching conservation, in the class-room, school grounds and the field, sources of help for the teacher from the State and community, and schemes for extending interest in conservation teaching beyond the biology department. The matter is presented as reports, from individual schools, on actual projects which they have carried out. Examples are grouped under such headings as: films, slides and film-strips; radio programmes (the script of a radio skit broadcast by one school is given in full); aquaria and terraria; collection, preparation and exhibition of specimens; nature trails and sanctuaries.

One can find good ideas in these accounts which could be adapted to the rather different organization of teaching in Great Britain, but unfortunately they are buried in such a welter of blatantly obvious detail that one wearies of the search. For example, under

"Field Trip Technique" the reader is told: "If transportation is to be provided . . . every precaution must be taken to guarantee comfort and safety". "Leaders' Responsibility. It is helpful to plan how to keep attention centred on the main objective of the trip. . . . Leaders should speak distinctly enough for all to hear". In describing a particular field excursion, negotiations for hiring the bus are given six lines; and three-quarters of a page is spent on reproducing, in entirety, the letter to parents asking approval for their children to go on the trip, and ensuring that they will be there to meet them on their return. In the same way, many of the photographs are no more than pleasant school groups taken in the field, telling the reader absolutely nothing.

Thus, while fully agreed that the teaching of conservation is a worthy cause, one finds it hard to recommend this book (with its inevitable high price) to teachers outside the United States.

Maurice Ashby

PROBABILITY AND STATISTICAL INFERENCE

The Foundations of Statistics

By Prof. Leonard J. Savage. (Wiley Publications in Statistics.) Pp. xv+294. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1954.) 48*s.* net.

My main objection to this book concerns its title. The first half deals with theories of probability in their subjective and objective aspects; the second half defines "statistics proper" as "the art of dealing with vagueness and with interpersonal difference in decision situations". Some of the words in this definition, perhaps, provide avenues of escape; but as Prof. Savage goes straight into minimax theory, to which seven out of the closing ten chapters are devoted, it is fair to construe his attitude as one which takes statistics to be a theory of decision. This view is not shared by many British statisticians, who rightly insist, first, on the fact that statistical inference is only part of statistics and, second, on the fact that decisions are only part of statistical inference.

As a contributor to the foundations of the theory of decisions, Prof. Savage's book is, however, welcome and stimulating. He cannot subscribe to the frequency theory of probability, but adopts a new approach to the subjective theory by referring it back, like the economists, to a theory of utility. Even here the decision aspect of the subject affects his thinking, but the treatment is interesting and well written.

In founding statistical inference on minimax theory, Prof. Savage starts on the defensive; for the minimax principle, in its crude form, says that we must act as if the worst will happen, which is reasonable enough in games against a clever adversary but is not reasonable against Nature. Prof. Savage, however, extricates himself from this difficulty, not without a struggle, and proceeds to ground which is more familiar to the ordinary statistician by discussing estimation and tests of significance. He has some rather startling things to say about accepted theories on this subject, but what he says is well thought out and deserves attention. It is to be hoped that his criticisms are not lost to sight under the controversy which they may well raise.

M. G. Kendall

A HANDBOOK FOR MUSEUM CURATORS

The Preservation of Natural History Specimens

Edited and Compiled by Reginald Wagstaffe and Dr. J. Havelock Fidler. Vol. 1: Invertebrates. Pp. xiii+205. (London: H. F. and G. Witherby, Ltd., 1955.) 42*s.* net.

The intention of this book is to bring together in one place a collection of all those techniques concerned with the preservation of natural history specimens that have proved to be efficacious. In addition to the old and well-tried methods, a considerable amount of original work is included.

The first part of the book consists of a systematic survey of the chief invertebrate groups from the Protozoa to the Tunicata. In each group there is given the method of killing (preceded by narcotization where necessary), of fixing and of preserving. In cases where special manipulation is necessary, this is described and sometimes illustrated with a diagram. For the detailed formulæ in each case the reader is referred to the appropriate section of the appendix. This saves an intolerable amount of repetition.

Clearly, there are groups which lend themselves to fuller treatment than others, and the Insecta are dealt with in considerable detail, particularly as to setting and mounting. One suspects that the beauty of Miss Begg's drawings has beguiled the editors into extending this section a little beyond the limits of necessity. In the section on Echinodermata no mention is made of the corrosive sublimate method of preserving the test, particularly of *Echinus*, recommended by the late R. T. Jackson, of Harvard (see *Mus. J.*, 29; May 1930). This method preserves both the spines and the lantern and is exceedingly simple to apply. It is also useful in the case of many Crustacea.

It may be noted that throughout the book the emphasis is upon the preservation of the external features. Anatomical dissection and display are not considered.

The second part of the book consists of five appendixes dealing with apparatus and instruments; reagents; labels and labelling; storage; and microscopy. Here there is a large and useful collection of formulæ and recipes, and the description of many pieces of apparatus, both simple and ingenious. Many of them are well known; some of them are new. It is perhaps the most useful section of the book. Among the formulæ for cements for sealing museum jars, the asphalt–guttapercha mixture is recommended, particularly for jars containing formalin, but it is equally effective for 70 per cent alcohol. I have found it quite the best general-purpose cement for museum work. Stitching on to cards is recommended in a number of cases. For wet mounts, stitching on to glass is perhaps the best method, and a later edition might include a simple technique for drilling holes in glass (see *Mus. J.*, 35; Nov. 1935); or maybe it will appear in Vol. 2.

In a work of reference, the importance of the index is obvious. In this case it performs its job efficiently and with the minimum of irritation. The general format of the book is excellent. The binding is strong, the paper good, the type clear, and Miss Begg's illustrations a real embellishment. The editors are to be congratulated on a very sound job, and one looks forward to the appearance of the second volume.

W. Eric Stoneman

Principles and Practice of Field Experimentation

By Dr. John Wishart and Dr. H. G. Sanders. Second edition. (Technical Communication 18 of the Commonwealth Bureau of Plant Breeding and Genetics, Cambridge.) Pp. vii+133. (Farnham Royal: Commonwealth Agricultural Bureaux, 1955.) 21*s*.

THE first edition of this book, published twenty years ago and for a long time out of print, was a landmark in so presenting the statistical outlook on field experimentation that it could be understood and used without advanced training in statistics. A new edition is therefore of considerable interest.

Dr. J. Wishart's section, on statistical principles and techniques, has been extensively revised; the result is an improved and up-to-date version, though the emphasis on expressing yields as percentages and the deletion of any graphical explanation of covariance analysis seem unfortunate. New chapters briefly discuss factorial design, confounding, and incomplete block designs. The author has met the difficulty that his subject has grown to a much greater extent than his few additional pages can contain, so that inevitably his account appears relatively less comprehensive than in the first edition. He is therefore the more to be congratulated on so well combining clear instructions for analysis of simple experiments with laying a sound foundation for further study. The contribution by Dr. H. G. Sanders is a general discussion of the practical aspects of field experiments, ranging from advice on when—and when not—to do experiments to rules for good recording. Changes from the first edition are slight; but the section remains perhaps one of the best published guides to experimental policy and details of field technique.

This book should be in the hands of all who conduct field experiments: they will learn from it much that will help their understanding of how statistical science can assist their work.

D. J. FINNEY

Le Microscope à Contraste de Phase et le Microscope Interférentiel

Par Maurice Françon. Pp. 150+1 plate. (Paris: Éditions du Centre National de la Recherche Scientifique, 1954.) 1,000 francs.

AFTER reading this book one is left wondering how it is possible to cover the subject so completely in only 125 pages. The answer is that the exposition is so clear and the selection of topics so excellent that scarcely a word is wasted. The only exception is the section on the applications of phase-contrast, which is too short and might be either omitted or expanded in future editions.

The first part of the book deals with general optical theory. After discussing the modification of the Airy disk pattern by aberrations and errors of focus, the formation of images of extended objects by coherent and incoherent light is examined. This is an excellent simple introduction to modern physical optics. The chapter on phase-contrast describes the main optical systems that have been used, including those for variable and coloured phase-contrast. Such questions as the effect of absorption in the phase plate and the resolving power are dealt with, but one could have wished for an account of the defects of the method, particularly the halo effect.

The final chapter is devoted to interference microscopy and is one of the best compilations so far available on this subject. Progress in this field is so rapid that it is sometimes difficult to decide priority. British readers may feel that the work of F. H. Smith does not receive proper acknowledgment, and that some of his designs have been unwittingly re-invented by others. The diagrams are for the most part excellent and a useful bibliography is added. A few minor printing errors were noticed. This is a book which can be read with profit by many and with real pleasure by all interested in optics.

An Introduction to the Calculus of Finite Differences

By Prof. C. H. Richardson. Pp. vi+142. (New York: D. Van Nostrand Company, Inc.; London: Macmillan and Co., Ltd., 1954.) 28*s*. net.

THIRTY years ago, the student of numerical analysis had no English text readily available save the brilliant pioneer work by Whittaker and Robinson, "Calculus of Observations" (1924). Since then the rapid growth of the subject, and the widening field of its applications, have produced many good books in English, some covering the whole field, some with a view to special applications. Prof. Richardson has based his book on a short course for actuaries and statisticians, but the course has also proved of value to electrical engineers and other technicians. The elements of finite differences, on a somewhat formal basis, are expounded in 120 pages: the operators E and Δ; the finite sum, with special reference to the Stirling numbers; the Euler and Bernoulli polynomials; interpolation and numerical integration; the gamma function; and simple difference equations. Only the simplest elements of the infinitesimal calculus are assumed to be known, and arguments are often plausible rather than strictly logical. The book should therefore serve as an outline of methods and problems, preparing the novice for the further study of more substantial treatises on the numerical or theoretical aspects of the difference calculus.

Some Beautiful Indian Trees

By Ethelbert Blatter and Walter Samuel Millard. Second edition, revised by William T. Stearn. Pp. xv+165+78 plates. (Bombay: Bombay Natural History Society; London: Wheldon and Wesley, Ltd., 1954.) Rs. 20; 30*s*. net.

THIS well-known book has been out of print for some considerable time, so now the second edition, edited by Mr. W. T. Stearn, is assured of a hearty welcome. Both the authors of the original book have died; but I feel sure that they would have approved of the way Mr. Stearn has carried out his part of the work, for this is not a mere reprint but an amended, corrected and enlarged account of the beautiful trees to be found in any large city in India. I am particularly glad to see that he has adopted the correct botanical name for the species where a change has become necessary.

The original plates were printed in England by a well-known firm of colour printers and were very well executed. It is not stated where the plates for the second edition were produced; but they are most unworthy of the book—cold, lifeless and falsely coloured.

The statement that there is a live specimen of *Amherstia nebilis* in one of the hot-houses at Kew is, alas, not true. The specimen referred to was lost during the War.

This book can be recommended to anyone who is visiting India.

N. L. BOR

ARTIFICIAL ICE-FORMING NUCLEI

By B. J. MASON and J. HALLETT
Imperial College of Science and Technology, London

THE fact that supercooled clouds commonly occur in the atmosphere at temperatures above −20° C., with the implication that efficient ice-forming nuclei are often deficient, and the possibility of inducing rain by supplying artificial nuclei, stimulated the search for substances which, when dispersed as an aerosol, might produce vast numbers of efficient, durable nuclei. The most important discovery was made by Vonnegut[1] in 1946, who found that when silver iodide smoke was introduced into a supercooled cloud in the laboratory, some ice crystals appeared when the temperature fell below −4° C. and that the numbers increased with decreasing temperature until, at about −15° C., most of the silver iodide particles appeared to serve as ice nuclei. Since one gram of silver iodide in solution could be vaporized to produce about 10^{16} nuclei, large-scale cloud seeding became a practical possibility. The success of silver iodide, which was chosen originally because the lattice constants of the hexagonal form are very similar to those of ice (see Table 1), initiated an intensive search for substances which might be either more efficient or less expensive than silver iodide. Papers have appeared from several different laboratories[1-6] reporting on the ice-nucleating ability of a wide variety of chemical compounds introduced either as smokes, sprays or as fine dusts into a supercooled cloud formed in an expansion- or mixing-cloud chamber. Except in the case of silver iodide, which is generally agreed to be the most effective of all the substances so far tested, the results obtained by the different workers are very conflicting; for example, substances reported as highly effective by one laboratory are found to be completely inactive by another.

We believe that in many of these experiments, spurious results may have resulted from the presence of trace contaminants (particularly silver and iodine) in the air, and of trace impurities in the various chemicals. We therefore decided to carry out very careful tests on those substances which have been reported as producing highly efficient ice nuclei by at least two independent workers. These include: silver iodide, lead iodide, mercuric chloride, silver nitrate, silver sulphate, silver sulphide, lead chloride, sodium chloride, iodine, ammonium iodide, sodium iodide, cadmium iodide, cobalt iodide, mercuric iodide and thallium iodide.

We have found that, if spectroscopically pure materials are used and great care is taken to exclude all traces of iodine and silver from the air in the experimental chamber, the great majority of substances reported as active by other workers fail to produce ice crystals in a supercooled cloud at temperatures above −40° C., when spontaneous nucleation of the supercooled droplets occurs.

That minute particles of silver may react very rapidly with iodine vapour in low concentration to produce particles of silver iodide was noticed by one of us several years ago. On opening a bottle of iodine near an open-top mixing-cloud chamber in which traces of silver aerosol may have remained from a previous experiment, the supercooled cloud became transformed into ice crystals within a few seconds; but iodine failed to produce crystals when introduced into a sealed cloud chamber filled with filtered air. A similar effect may be demonstrated by causing a small electric spark between two thin silver wires in a large flask containing a small iodine crystal; on passing air through the flask into a cloud chamber, the supercooled water cloud may be transformed completely into ice within a few seconds of forming the spark. These experiments suggest that should any silver salt which may either decompose on heating or dissolve inside a droplet be dispersed into a supercooled cloud containing small traces of iodine, particles of silver iodide might be formed and cause the appearance of some ice crystals at high temperatures; a similar result might be expected if an iodide were dispersed in an atmosphere containing traces of silver.

Experimental Procedure

Our nucleation tests were carried out in a modified version of the continuously sensitive diffusion cloud chamber described by Schaefer[7]. The chamber, shown in Fig. 1, consists essentially of a vertical column, 50 cm. high, 30 cm. in diameter, cooled at the bottom and held at or above room temperature at the top, where water is evaporated into the chamber to produce a convectively stable, thermally stratified cloud which, in the absence of ice nuclei, exists in the liquid state above the −40° C. isotherm. The lower plate, supported by a solid aluminium block, is maintained at about −60° C. by surrounding the lower part of the apparatus with 'dry ice'. The top plate, when unheated, remains at about 5 deg. C. below room temperature, and the positions of the 0° C. and −40° C. levels are roughly as indicated in the diagram. A water reservoir, sufficient for several days, is mounted on the underside of the top plate and may be electrically heated. The plane, rectangular walls of the chamber are made of 'Perspex'. A deep cold zone is established by the inner copper walls soldered to the base plate. The outer plate glass walls serve to reduce the lateral inflow of heat and to widen the vertical temperature gradient, which is measured

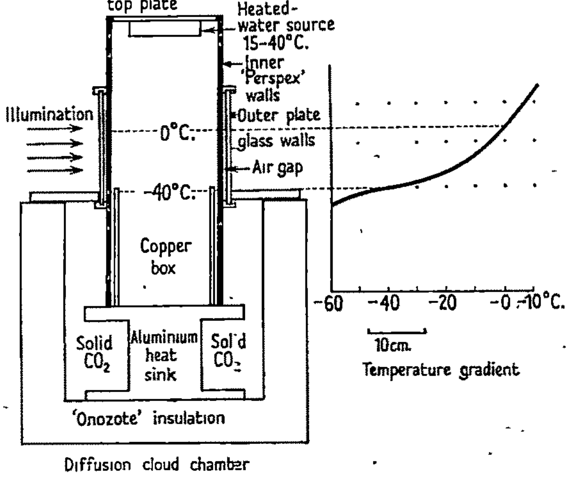

Fig. 1. The diffusion cloud chamber

by a thermocouple attached to a micrometer head. The vertical separation of the 0° C. and $-40°$ C. levels is about 10 cm. A horizontal network of thermocouples serves to check that the horizontal temperature distribution is reasonably uniform.

Before commencing a nucleation test, the chamber is thoroughly cleaned, sealed and left for some hours for any particles present to fall out and leave very clean air in which condensation on the ion-tracks of cosmic rays may be seen. Artificial nuclei are then introduced through valves in the top plate, and their nucleating effects are observed or photographed by viewing normally to an intense beam from a high-pressure mercury lamp passing horizontally through the chamber. Within about one minute of entering the top of the chamber, the nuclei arrive at the 0° C. level, below which one watches for the first appearance of glittering ice crystals, the temperature at this level being measured. The threshold temperature for nucleation will depend upon the quantity of nuclei introduced and the volume of the observational space ; but in these tests we adopted the temperature below which more than one ice crystal appeared among about 10^4 water droplets. The nuclei were produced either by spraying a solution or by vaporizing the substance on an electrically heated wire in an atmosphere of clean nitrogen to prevent oxidation effects. Blank tests were always carried out with the heated wire and with distilled water to check that they produced no effective nuclei.

Because particles, having become centres of condensation, take only about 10 sec. to fall between the 0° C. and $-40°$ C. levels in the diffusion chamber, it might be argued that their failure to produce ice crystals at temperatures above $-40°$ C. might be attributed to their having long activation times. To meet this point, simultaneous tests were also made with a large mixing-cloud chamber of capacity 400 litres, where the nuclei were introduced into a continuously generated supercooled cloud and remained in suspension for some minutes. With this arrangement it was possible to detect whether ice crystals were produced at temperatures above $-20°$ C.

Nucleating Ability of Various Chemicals

In early tests, ammonium iodide, potassium iodide, sodium iodide and iodine vaporized on an electrically heated nickel wire all produced ice crystals in the diffusion chamber at temperatures above $-20°$ C., as reported by other workers. But as the particles, being highly soluble, rapidly went into solution when condensation occurred upon them, it was difficult to understand how they could have acted as ice-forming nuclei. Our suspicions that the iodine compounds were reacting with silver or lead impurities in the nickel wire to produce either silver iodide or lead iodide received support when two such wires were sparked in iodine vapour to give large numbers of ice-forming nuclei active at temperatures above $-15°$ C. When the tests were repeated with spectroscopically pure nickel wire, the four abovementioned substances and also cobalt, mercuric, thallium and stannous iodides did not produce significant numbers of ice crystals at temperatures above $-40°$ C. Similar results were also obtained for sprayed solutions of ammonium, potassium, sodium, cobalt, stannous, magnesium, manganous and nickel iodides and iodine.

The early tests on silver salts (other than silver iodide) did not give consistent results. When smokes or sprays of silver nitrate or sulphate were introduced into a freshly cleaned diffusion chamber, only a very low concentration of ice crystals appeared at first, but the numbers gradually increased, and after about twenty minutes, these salts appeared to have about the same level of activity as silver iodide, with some crystals appearing at about $-5°$ C. and complete glaciation of the cloud occurring at $-15°$ C. Although these results were in accord with those of other workers, it was again difficult to accept them at face value, in view of the high solubility of silver nitrate and silver sulphate. Furthermore, when silver nitrate was sprayed into a large mixing chamber containing supercooled cloud at $-20°$ C., no significant increase in the number of ice crystals occurred. However, on introducing a small iodine crystal for only two seconds, the whole cloud became transformed into ice crystals. This demonstrated, in striking fashion, the influence of small traces of iodine, and we attribute the gradual increase in the number of crystals appearing in the diffusion chamber after the introduction of a silver salt to the slow exudation of iodine adsorbed on the 'Perspex' walls. That minute traces always remained even after the most careful cleaning was demonstrated by sparking two silver wires directly in the chamber ; ice crystals appeared at temperatures below $-5°$ C. and were presumably formed upon nuclei of silver iodide. When the silver nitrate was tested in a glass vessel freed completely of iodine by baking, no ice crystals appeared. From these and other tests, we are convinced that silver nitrate and silver sulphate are not capable of nucleating supercooled water, and that they appeared to be highly effective in other experiments[2,4,6] only because they formed silver iodide in the presence of small quantities of iodine.

Our results for lead iodide confirm those of previous workers in finding it to be a very efficient nucleating agent, producing a significant number of ice crystals in both chambers at $-7°$ C. and complete glaciation at $-15°$ C. ; it is therefore only slightly less effective than silver iodide. On the other hand, both lead nitrate and lead chloride are found to be inactive in the diffusion chamber, and also in the mixing chamber, at temperatures above $-20°$ C. Deliberate contamination with small quantities of iodine, however, brings about rapid formation of ice crystals, presumably through the production of lead iodide.

In all these experiments the presence of ice crystals is inferred solely from the appearance of glittering particles in an illuminated region of the supercooled cloud. That this may not be an infallible test was indicated by the appearance of such particles in the upper, warm regions of the diffusion chamber when smokes and sprays of mercuric chloride, and finely powdered cupric sulphide, stannous oxide and beryllium oxide were introduced. The glittering of the particles was much reduced once they had fallen several centimetres and become involved in condensation, but in the case of cupric sulphide and mercuric chloride, the scintillation increased again below the $-15°$ C. and $-25°$ C. levels respectively. The collection of the crystals formed at these low temperatures and their observed melting under the microscope suggested that ice crystals were being produced. Since the cupric sulphide was only of commercial grade, further tests, including spectroscopic analyses, are being carried out. But a recent report[6] that finely powdered copper sulphide causes complete glaciation of a supercooled cloud at $-6°$ C. may be questioned ; it seems that scintillation of the copper sulphide particles themselves may have been mistaken for the appearance of ice crystals. In the case of beryllium oxide, no crystals were observed between the 0° C. and − 40° C. levels. Sodium chloride, manganese dioxide, manganese chloride and cadmium sulphide were found to be similarly inactive. Introduction of powdered stannous oxide produced a cloud of glittering particles throughout the whole depth of the chamber.

The only chemical compounds which we have found to be definitely active as ice-forming nuclei at temperatures above −40° C. are silver iodide (−5° C.), lead iodide (−7° C.) and mercuric chloride (−25° C.), the temperatures in brackets indicating the threshold limits of activity.

Behaviour of Silver Iodide Nuclei

Silver iodide is certainly the most effective ice-nucleating substance so far discovered. Its efficiency depends very much, however, upon the method of preparation. In fact it occurs in two crystal forms at room temperature—a hexagonal (wurtzite) arrangement and a cubic (zinc blende) arrangement, the cubic form being regarded as the stable form at temperatures below 135° C. The hexagonal form is the thermodynamically stable one between 135° C. and 146° C. Above 146° C. both types may become transformed into a new high-temperature cubic form. The unit-cell dimensions of the three forms are shown in Table 1.

Table 1

Substance	Crystal form	Unit dimensions (A.)
Silver iodide	Hexagonal (wurtzite)	$a = 4 \cdot 58$, $c = 7 \cdot 49$
	Cubic (zinc blende)	$a = 6 \cdot 47$
	'High temp.' cubic	$a = 5 \cdot 03$
Lead iodide	Hexagonal	$a = 4 \cdot 54$, $c = 6 \cdot 86$
Ice	Hexagonal	$a = 4 \cdot 52$, $c = 7 \cdot 37$

When silver iodide is vaporized at several hundred degrees centigrade, X-ray and electron-diffraction patterns of the smoke show that it consists of a mixture of the hexagonal and cold cubic forms, with some indication of the hexagonal form being more dominant the higher the temperature of the source[8]. Whether the hexagonal or the cubic form provides the more efficient ice nuclei has not yet been established, but it is perhaps worth noting that the atomic array in the (111) planes of the cold cubic structure and the (001) planes of the hexagonal form are geometrically identical, the lattice spacing being 4·58 A. in each case.

Silver iodide generators used in cloud seeding utilize silver iodide dissolved with either sodium or potassium iodide in acetone. The solution is sometimes atomized through a nozzle by compressed hydrogen or propane and the spray ignited; alternatively, it is sprayed into a kerosene flame. Another method is to soak coke nuts in the solution and burn these in a ventilated furnace.

Electron-diffraction patterns, taken at the Imperial College by Lisgarten (unpublished), produced by the vaporization of silver iodide–potassium iodide and silver iodide–sodium iodide mixtures, suggest that these techniques may not be the most efficient. The patterns produced by silver iodide–potassium iodide mixtures show little or no trace of either silver iodide or of potassium iodide but suggest that mixed crystals are being formed (see Fig. 2). The silver iodide–sodium iodide mixtures reveal no trace of hexagonal silver iodide but produce patterns consistent with those of either the cubic form of silver iodide or of sodium iodide, which have an almost identical lattice spacing; alternatively, mixed crystals of both substances with unaltered lattice spacing may have been formed. X-ray and electron-diffraction patterns of smokes produced by the vaporization of pure silver iodide crystals include broad, diffuse rings indicative of an amorphous rather than a crystalline structure. It seems that the silver iodide, having become partly decomposed by heating, fails to form good crystals during quenching; certainly electron micrographs show the particles to be malformed, with few well-defined crystalline shapes.

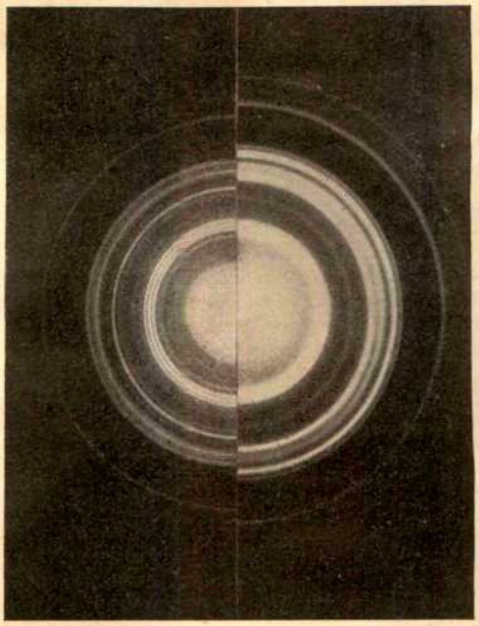

Fig. 2. *Left:* electron-diffraction pattern of a smoke produced by vaporization of a silver iodide–potassium iodide mixture. *Right:* pattern produced by vaporization of silver iodide *in vacuo*. Note that the pattern produced by the mixture shows no rings which can be identified with those of silver iodide. (Photo by N. D. Lisgarten)

If the silver iodide nuclei are produced in a reducing atmosphere such as will be provided if acetone and particularly hydrogen are burned at high temperatures, their surface layers may be reduced to metallic silver and their ice-nucleating ability largely inhibited. This effect appears to be greatly enhanced if the crystals are irradiated with ultra-violet light (cf. the reduction of silver bromide to metallic silver in a photographic emulsion), which explains why silver iodide may quickly lose its ice-nucleating properties when dispersed into the atmosphere during strong sunshine. According to tests made by Smith, Seely and Heffernan[9] the activity of nuclei from a hydrogen burner decays to about a hundredth of its initial value after an exposure of only 15 min.

The discovery of a method for producing large quantities of highly efficient and durable silver iodide particles is of considerable practical importance. Lead iodide, which is not so susceptible to photolytic decomposition, appears to merit further investigation as a possible substitute.

THE IMITATION OF MENTALITY*

By Dr. W. GREY WALTER
Burden Neurological Institute, Bristol

DURING the past twenty years, electronic methods have revealed many exciting and useful relations between the patterns of electrical activity in the brain and the temperament, mentality and behaviour of human subjects. These discoveries are acknowledged aids to the diagnosis of brain disorders ; but there is still no general theory of normal brain action, nor are there convincing special hypotheses about the relation between the known functions of the brain and thinking. Such theories as have been advanced have been too ambiguous to suggest clear-cut experiments, since their expression in words leaves so much to the imagination. On the other hand, attempts to express notions about the brain in rigorous mathematics are hard for experimentalists to understand. Since the scientific method depends upon the steady development of clear working hypotheses, advances in the understanding of brain function will be slow until this dilemma has been resolved. One method which seems promising is to embody the components of a hypothesis in a working model, observing carefully the rules of parsimony and the test of prediction ; the model must contain no redundant parts and is valid only if its behaviour permits prediction of behaviour beyond that originally intended. A model or analogue of this sort is, in fact, a crystallized hypothesis ; it should be clear and brittle. When it breaks down, as all working hypotheses must, its failure is obvious and explicit ; a verbal hypothesis can yield almost imperceptibly and change its form under the pressure of facts.

From time to time most artificial systems for communication and calculation have been used as models of the brain. Automatic telephones, electronic computers, totalizators have all been invoked in turn to illustrate certain aspects of higher nervous function. None of these, however, serves the purpose, and during the past few years several models have been built specially to illustrate hypothetical mechanisms underlying living behaviour.

The simple concept of reflex action, as defined by Sherrington, is so simple that it scarcely needs illustration ; none the less, the feedback principle of error cancellation, which appears so frequently in modern engineering design, is basically a reflex. It is strange that the power of such a system has only recently begun to be appreciated by engineers. The principle of the automatic governor devised by Watt was analysed by Maxwell before the physiology of reflex action had been worked out ; but it has taken nearly a century for the advantages of negative feedback to be exploited. Nowadays, a modern home is likely to contain at least half a dozen mechanical reflexes, and motor-cars, ships and aeroplanes would be unmanageable without them. The extra-ordinary properties of the reflexive system are seen clearly only when several elements are capable of free interconnexion with one another. In such a complex system, even if the activity is limited to all-or-none binary responses, the number of patterns of interconnexions is enormous ; if the number of modes of connexion be M and the number of elements n, then for values of n greater than 6, M is approximately $2^{(n^2-n)}$. The inferences from this simple relation are encouraging to brain physiologists, who often feel dismayed by the joint challenge of the ten thousand million nerve elements in the human brain and the associated complexity of human mentality. It would be comforting to be able to suppose that the vast congregation of nerve cells in the head might act in large clumps ; obviously it will never be possible to consider the individuality of each nerve cell. Yet large numbers are required for any mechanistic hypothesis of mentality. Fortunately, very large numbers can appear from the free intercommunication of a few elements as suggested above. If we must provide a model capable of forming a fresh pattern every tenth of a second for the span of a long lifetime, we must ask how many elements would be necessary. The answer is : six. In other words, an artificial brain with six freely interacting elements could get into more than ten thousand million different states. It is not suggested that the human brain contains only six functional elements ; what may be important is that, with the several hundred that have already been identified and named, a variety of character and experience could be generated comparable with what we know of human individuality and versatility.

In order to illustrate what sort of behaviour can be derived from reflexive systems alone, a number of models has been built. These contain only two 'nerve elements' in the form of wireless valves and relays, two sense organs (a simple 'eye' and a skin) and two effectors (a motor for crawling and one for steering). As well as this, it is arranged that the eye shall scan in a circular fashion so that it can distinguish and respond to a light signal wherever this may be. One mode of behaviour is this scanning for signals, the next is the positive response to a moderate light which interrupts the scan and leaves the model facing the light and crawling towards it. Another mode is the avoidance of bright light, another again the circumvention of obstacles when the skin is touched. The behaviour of these models is entirely unintelligent and there is no memory or learning ; nevertheless, they behave in a strangely 'purposeful' fashion, find their way out of an enclosure or into their hutch, seek out moderate lights and avoid bright ones. They are capable of a rudimentary form of self-recognition and mutual recognition and can be made to 'feed' themselves. Although anatomically they resemble very primitive creatures—Rotifera—in some respects, they are more sophisticated than lower mammals. Their mock-biological name is *Machina speculatrix*, since, unlike most machines, which are essentially passive tools, they actively investigate and explore their environment. It would seem that spontaneous exploratory activity, self-control, the solution of Buridan's dilemma, moderation, discrimination between end and means, self-recognition, and mutual recognition can appear at reflexive levels and do not require more elaborate anatomy or physiology. An inference from this proposition is that the relative passivity of the mammalian spinal cord (where reflex action has been most thoroughly studied in real animals) is a specialized attribute of animals with highly developed brains, and that the elaborate form of behaviour in sub-mammals known generally as 'instinctive' is a combination of reflexive patterns which have not been subordinated to the learned modes typical of mammals and particularly of primates.

---

* Substance of a Friday Evening Discourse at the Royal Institution on March 16.

Another model has been built to show how the characters of the innate releaser mechanism can be achieved in a single mechanism, and how this form of behaviour may vary with activity and be particularly vulnerable to changes in the internal environments such as 'starvation' or 'satiety'.

Of greater relevance to the study of human mentality is the imitation of the process of learning by association or conditioned reflex formation. Analysis of this process as it actually occurs in animals suggested that, in the simplest case, it could be considered as involving a chain of seven distinct operations, known respectively as: (1) differentiation of specific stimuli; (2) extension of neutral stimuli; (3) mixing of (1) and (2); (4) summation of degrees of coincidence achieved in (3); (5) activation of storage system when degree of coincidence in (4) has exceeded chance expectation; (6) storage of the information that the coincidence has exceeded chance expectation; (7) combination of the stored information with a fresh neutral stimulus to provide a novel mode of responding to the previously neutral, now 'conditioned', stimulus.

These operations can be embodied in a working model, and such a model can be seen to 'learn' in the sense that it can discriminate between random events and those which are significantly related, and can then respond to a part of the significant association as if the whole were present. An important inference is that learning in this sense and pattern recognition are essentially the same process. A pattern may be defined as a class of relations between events which is likely to operate a learning mechanism.

The actual models (known as *Machina docilis*) of learning display several peculiarities which at first seemed to be faults but may be instructive. When set up to demonstrate a defensive rather than an appetitive conditioned reflex, it was found that the 'learned' pattern was often self-maintaining; it was not easily extinguished by lack of reinforcement. Reconsideration of animal behaviour and of human neuroses suggests that this may indeed be a property of complex behaviour based on the avoidance of pain, and that the intractability of obsessional and compulsive neuroses may be due to their liability to self-reinforcement. Again, when a neutral stimulus is given to the model in a carefully timed rhythm, the system can be induced to respond as if it had 'invented' a specific stimulus which it had never, in fact, experienced. This rudiment of originality also seemed tiresome at first; but bizarre illusions and fantasies can, in fact, be induced in some human subjects by rhythmic stimuli and it is possible that, as in the model, this effect may be due to the direct activation of a storage circuit by the cumulative action of the imposed rhythm.

The fundamental notion underlying this description of associative thinking is that mentality is based on a statistical or probabilistic analysis of experience rather than a logical or deterministic one. In fact, mentality could be defined as the rate of change of behaviour induced by statistically significant associations. This notion is not so far removed as it may seem from the real problem of brain and its function; a capacity to learn is the diagnostic character of brain, and the hypothesis that a learning brain is perpetually scanning the world of experience for statistically significant information suggests a fresh experimental approach to the problem of how animals learn. In fact, reconsideration of the protocols of conditioned reflex experiments designed to induce 'experimental neuroses' has disclosed a previously unsuspected pattern in those stimulus arrangements which were found to disturb the animals. It looks very much as though an animal—human or otherwise—in a learning situation is acting as if it were a statistical computer set to accept, as significant, odds greater than 1,000 to 1 against chance association. If the basis of learning is the computation of contingency, then most animals are considerably more sceptical than professional statisticians, who generally consider odds of 100 to 1 against chance as indicating significance.

Experiments suggested by these analogies of reflexive and associative behaviour are now in progress. Naturally, the hypotheses will be found inadequate; but there is no reason why other models should not be designed to match observation still more closely. There is even a possibility that, in the more distant future, devices that began as instructive toys may develop into powerful tools. We are already entering a phase of our culture when our arithmetic, algebra and even our material production are being delegated to mechanical extensions of our five wits. Eventually, the mental functions of conjecture and imagination may also be shared with the successors of these humble mechanical 'protozoa'.

OBITUARIES

Prof. H. F. Baker, F.R.S.

Henry Frederick Baker, who was Lowndean professor of astronomy and geometry at Cambridge from 1914 until 1936, died on March 17. His name is chiefly remembered as the founder of a vigorous and distinctive school of geometry, but his influence on the mathematical life of Britain was wider than this.

Baker was born in 1866 and was educated at the Perse School and at St. John's College, Cambridge. His progress as a student was impeccable—joint Senior Wrangler in 1887, first division of the first class in the Mathematical Tripos of 1888, and Smith's Prizeman in 1889, in which year he was elected to a fellowship at St. John's which he held until his death nearly sixty-seven years later. So at the age of twenty-three he embarked on the career of a Cambridge don which he was to follow throughout his life. He did not travel widely; but he had contacts with mathematicians in all parts of the globe, and a visit to Göttingen to study under Felix Klein had a decisive influence on his development as a mathematician. He thus began his work in Cambridge while Cayley, Stokes and Adams were still the dominant influences in Cambridge mathematics. Cayley, who shared with Klein the role of chief formative influence in Baker's mathematics, did not die until 1894. It was very appropriate that, when a lectureship was founded in memory of Cayley, Baker was appointed the first holder, in 1903.

Baker quickly threw himself into the work of a college don, and was soon carrying a load of teaching which would make the modern don shudder. He had to teach all the subjects required for the Mathematical Tripos; but in his formal lectures he specialized in the theory of functions and geometry. His principal interest at this time was the theory of algebraic functions, and in spite of his heavy teaching duties he managed to get through a prodigious amount of reading. His first book, "Abel's Theorem and the Allied Theory" (1897), is a monumental work, and his second book, "Multiply Periodic Functions" (1907), is a thorough study of the theory associated with theta functions of two variables. But his papers cover a much wider range—the theory of functions, continuous groups, multiple integrals, projective and algebraic geometry. While a good deal of his original work of this period has been superseded by modern developments, much of permanent value remains, and I recall the pleasure which it gave Baker, only a couple of years ago, to supply reprints of a paper fifty years old which a leading group of American mathematicians was anxious to obtain.

In 1913, Sir Robert Ball, the Lowndean professor who had followed Adams, died, and early in 1914 Baker was elected his successor. The six previous holders of the chair had all been astronomers, and the University statutes of the period did not explicitly allow the Lowndean professor to specialize either in astronomy or in geometry; so Baker, with a characteristic devotion to duty, immediately offered a course on periodic orbits, not in place of, but in addition to, the lectures on the theory of functions which he had been scheduled to give before his election. He kept up his lectures on dynamical astronomy for many years, and a number of distinguished astronomers have spoken of these lectures in the highest terms. But from 1914 onwards he concentrated more and more on geometry, and for some years before he retired his lectures and writings were all on geometry. During his long retirement he continued to work on geometry, and in 1943 he published "An Introduction to Plane Geometry", followed in 1946 by a Cambridge Mathematical Tract, "A locus with 25920 linear self-transformations"; and only two months before his death he completed, in spite of failing eyesight, a commentary on some of his earlier books.

After the First World War, Baker set about building up a school of geometry, and succeeded so well that the 'Baker school' still has its distinctive character. At first the emphasis was primarily on projective geometry, along the lines of von Staudt and Reye. To this period we owe the first four volumes of his "Principles of Geometry", which became the bible of his followers. This work reaches its climax in the fourth volume, which deals with the numerous special configurations and loci in four dimensions and their relations with classical configurations such as the double-six in three dimensions, with infectious enthusiasm and many characteristic touches. Later, he lectured more on the birational theory of surfaces, as developed by the Italian geometers, and out of these lectures grew the fifth and sixth volumes of his "Principles". His interest in Italian geometry, however, began much earlier, arising naturally from his work on algebraic functions, and in 1912 he made it the subject of his presidential address to the London Mathematical Society, perhaps the most influential single article he ever wrote. But what remains most vividly in the minds of all his pupils is the burning enthusiasm he brought to all his teaching, and the enthusiasm he kindled in his audiences. No one ever attended his lectures on geometry without gaining something which remained with him throughout his life.

W. V. D. HODGE

Prof. Léon Bertin

On February 4, in his sixtieth year, Prof. Léon Bertin was killed in a motor-car accident on the frozen roads outside Paris. He had held the chair of herpetology and ichthyology at the Muséum National d'Histoire Naturelle since the death of Pellegrin in 1944.

Bertin graduated at the École Normale Supérieure of Paris in 1920 and was awarded a bursary to study for a doctorate. Under Prof. Bouvier he had been initiated, as he said, "au dur métier de la systématique" in the field of entomology, and he now took up the study of sticklebacks in a way that would have astonished Mr. Pickwick. Johannes Schmidt had just demonstrated the value of biometry in analysing the races of *Zoarces* and contrasting their diversity with the homogeneity of the populations of the European eel. Bertin applied like methods to sticklebacks and published on them a series of papers culminating in the classical "Recherches bionomiques, biométriques et systématiques sur les Épinoches (Gasterostéidés)" (1925), which won him his doctorate. The three-spined stickleback shows, in the amount of dermal ossification, a diversity which, expressed in the number of lateral shields, lends itself to numerical analysis. By examining ten thousand specimens from forty-five localities in France and North Africa, Bertin was able to correlate the degree of armature with age, salinity and latitude. Although later work by Heuts has shown that his conclusions were over-simplified, Bertin produced order from chaos and laid a firm foundation on which others have built. The French sticklebacks proved to have a life-span of fourteen to eighteen months. Later, Bertin studied large samples from Iceland and Greenland and demonstrated that these do not become sexually mature until their third or fourth summer, and that they thus conform to the rule of longer life-span in higher latitudes.

This work was followed by studies on bathypelagic eels and then on those enigmatic eel-like fishes, the Lyomeri. Bertin was entrusted with rare and precious material of these groups collected during the cruises of the *Dana*. As well as a number of smaller papers, he published three *Dana* Reports on them (the first in collaboration with Roule), and he had work on them in hand at the time of his death.

Throughout his career Bertin was associated with the University of Paris and the Museum. His courses at the University were much appreciated, and that on the eels was published in book form in 1942.

While still 'Sous-Directeur' at the Muséum, Bertin organized and directed the indexing of the rich but neglected departmental library of offprints and journals. He appreciated the effect of environment on his staff no less than on the sticklebacks, and visitors to his laboratory in the Jardin des Plantes after the War were impressed by its pleasing decoration and efficient organization as well as by the ready assistance they received. No longer do we read in ichthyological papers, "Type in Paris; cannot be found". Under Prof. Bertin the types were found and catalogued. Five fascicles of this catalogue have been published by the Museum, and Unesco funds were to have been made available for the rest.

Bertin developed a talent for popularization. The biggest work of this kind from his hand is "La Vie des Animaux" (1949–50). His contribution to the "Traité de Zoologie" is now in the press and due to appear shortly; so, too, is an English edition of "Les Anguilles".

Bertin served his country as a soldier in both World Wars, and received the Croix de Guerre for courage under bombardment in 1940. A man of distinguished appearance, his personality was dynamic and gay, and it is this that gives a special sadness to his sudden and tragic end. He leaves a widow and three children.

E. Trewavas

Prof. E. D. Merrill

Elmer Drew Merrill was born on October 15, 1876, in a village near Auburn, Maine; there he grew up amid country sights and sounds. From the village school he passed to a high school in Auburn, walking the three miles in all weathers; and finally to the State College in Orono, which during his years became the University of Maine. He has written that his biological teacher roused his enthusiasm for field work; but the love of the wilds was already in him: late in life the Maine woods continued to attract him. He was compelled to earn as he learned, serving, for example, as a student-assistant in the botanical laboratory. Having graduated B.S. in 1898, he held a minor appointment until in the next year he was appointed an assistant agrostologist in the Department of Agriculture at Washington.

Merrill's excursions in Maine had provided him with a small collection of about a thousand dried plants; and his first entrances into print were records of Maine plants. Three years at Washington led to half a dozen short papers on grasses, along with a valuable training in method. Unexpectedly, he was offered the post of Government botanist in the Philippine Islands. He demurred as untrained for such a responsibility; but it was pressed on him and he arrived in Manila in March 1902, having visited the botanical establishments in Ceylon and Singapore on the way. His beginnings were certainly an adventure: an unfurnished room awaited him. The herbarium of Philippine plants, made by Vidal and nomenclaturally co-ordinated at Kew, had been destroyed in 1897 by an accidental fire; a second herbarium which would have thrown light on the naming in the third edition of Blanco's "Flora" had been destroyed in the fighting of 1899. Such books as there had been, if not burned, had been purloined; and he started from scratch. In twenty-two years his new herbarium grew into a splendid collection of 270,000 mounted sheets and he would have written a descriptive "Flora" had he been left with the opportunities. He had travelled in all parts of the Archipelago, had had loyal support from forest officers and others interested in plants and had made very effective use of trained Filipino collectors. His office methods were direct and purposeful; and as no flora can be studied profitably in isolation he had extended his collecting of data to surrounding lands. This collection was destroyed by the Japanese. It had held the reference material for a vast output of taxonomic papers; but the magnitude of the loss on its destruction is lessened by the existence of duplicates in many herbaria which he, thinking internationally, had distributed abundantly.

As a prelude to the projected Flora of the Archipelago, he published in 1912 a descriptive "Flora of Manila" to support teaching in the University, and to teach was immediately added to his duties. In 1919 a further portion of his time was withdrawn from botanical research, for he was required to take the post of director of the Bureau of Science. His reaction to added work was to lengthen the day; but he could and did turn the projected descriptive "Flora" into an "Enumeration of Philippine Flowering Plants", which appeared during 1923–26, the fourth and last volume holding a masterly phytogeographical review.

Merrill had married in 1907, and for the sake of the children a home was made in the United States; he spent part of his leave in 1921 with them in California, returning to Manila alone. In 1923 the University of California offered him the appointment of dean of its College of Agriculture. He accepted and served there for five years. Then he was invited to be director of the New York Botanic Garden, and he also served there for five years. In 1935 he was asked to take the post of administrator of the Collections of Harvard University (otherwise director of the Arnold Arboretum), which he held for eleven years. All three posts were difficult by reason of conflicting interests; but he was remarkably successful in all of them. One who knew him intimately wrote of his qualities—quickness of perception, unfailing patience and courtesy, great store of common sense, promptness in taking action, approachableness, and consideration for others. The University of California at Berkeley joked about his early hours used in naming collections that followed him from Manila. His reliability drew unexpectedly large donations towards his projects. In New York during the distressing slump of 1930 as many unemployed stenographers as he could employ were put at his service, and he used their labour for the innovation of incorporating descriptions and illustrations among the herbarium sheets. The Harvard University units that were under his charge were commonly spoken of as the 'orphans'. His first annual report referred to the need of somehow placing them in the 'family'; but re-organization was deferred until after his retirement. His last annual report gives a retrospect of his eleven years and shows the orphans, though still orphans, growing healthily.

In advance of his seventieth birthday Merrill was released on request from administrative duties at the end of the Arboretum's fiscal year (June 30, 1946). He remained Arnold professor of botany and continued his botanical work. The dispersal of cultivated plants had become a major interest. He had criticized in 1920 the extravagant diffusion theories of O. F. Cook, and later, when at New York, had had occasion to attack fresh unsubstantial claims of pre-Columbian transfers of useful plants between the Americas and the rest of the world. In 1950 in Washington anthropological friends asked him to sum up the case against new diffusionists, and shortly afterwards one of the diffusionists challenged him to prove his position. In the next year, being in London and at work on plant distribution, it occurred to him that, as the introduction of weeds offers evidence parallel to the introduction of cultivated plants, he could use the old records in the British Museum for his purpose, and he began to write his last book, "The Botany of Cook's Voyages". Unfortunately he was taken ill and the work was interrupted; he recovered and resumed it, but was taken ill again. At a second resumption he completed the writing, and with the help of others the book was published in the autumn of 1954, by which time he was exceedingly ill; but he lived to February 25 of this year. He had received many honours and had obtained an international position in his own branch of botany that was unmatched. I. H. BURKILL

Sir Cyril Norwood

WITH the death of Sir Cyril Norwood on March 13, at the age of eighty, there passed an outstanding figure in the world of education of the past fifty years. His influence was comparable to that of men like Arnold in the nineteenth century. Norwood, a brilliant classical scholar from Merchant Taylors' School, gained the highest honours at Oxford and spent several years in the Home Civil Service before entering the teaching profession at Leeds Grammar School in 1901. Five years later he became headmaster of Bristol Grammar School, and during fifteen years he transformed its standards and achievements. Then followed nine years, perhaps the zenith of his school activities, as master of Marlborough College, before his migration to the headmastership of Harrow and in 1934 to the presidency of St. John's, Oxford, his former College, from which he resigned in 1946 because of his wife's ill-health.

Throughout his whole educational career, Dr. Norwood brought what has been called the 'modern approach' to bear upon the organization concerned. Without relinquishing his firm belief both in the value of a classical training for the study of language and in the study of ancient history, he was among the first to emphasize the need for a greater emphasis on the teaching of modern languages, geography, science, and later of economics. His underlying aim seemed to be to modify where necessary an existing system of education—sometimes stereotyped or stagnant—so as to meet the needs of a changing world or society, and the present arrangement of the General Certificate of Education examinations owes much to the analysis of the Norwood Report of 1943. The vast impact of the sciences, pure and applied, during the post-war years, came a little too late for him to play an active part; but it might have been interesting indeed to see his outlook upon it.

Norwood had a strong, compelling, even if at times enigmatic personality. In appearance he might have been likened to Lord Kitchener, and the methods of the two men were at times similar. His deep religious beliefs were matched by a conviction of the essential correctness and desirability of his educational policies. This caused him at times to appear despotic and ruthless. He brought criticism upon himself from some by the widespread publicity he gave to his ideas. Yet he did not deliberately seek the publicity which followed as a result of the innate conviction of his mission and his desire for progress. The value of his work was proved by the successes of his pupils and masters alike. His reserve, possibly a shyness, made him appear unapproachable to many; but others learnt to know him as a kindly, human personality and a friend of good counsel. Of all the talks which he gave throughout his life, few could have surpassed in simple, penetrating eloquence that which he delivered in the chapel of his College on the cessation of war in 1945. For him, too, it was to be the epilogue of a life filled with interest and achievement.

Dr. Robert Pohl

OVER a period of fully half a century, developments in the design of rotating electrical machines have been influenced by the work of Dr. Robert Pohl, whose death occurred on March 15. He was seventy-seven years of age.

Born at Hamm, Westphalia, Pohl received his university education at Hanover and his first industrial experience with the firm of Lahmeyer in Frankfurt. At the time at which Pohl entered the electrical industry, direct-current practice was well established and the utilization of alternating current was undergoing intensive development. The dynamo was already an efficient and relatively refined machine awaiting only the devising of means further to improve its commutation. Pohl's first contribution to the advancement of electrical knowledge, made when he was little more than a student, was towards elucidating the mode of action of the interpole or commutating pole then newly invented.

Pohl went to England in 1904 to join the staff of the Phoenix Dynamo Co. of Bradford, and he was appointed chief engineer of the Company at the age of twenty-eight. He was responsible for the production by that Company of the first machine with commutating poles to be built in Great Britain. From 1905 onwards Pohl contributed, except for the period of the First World War, to the literature of electrical machinery. His more important early papers were on direct-current machines, but by 1914 he was writing on turbo-alternators.

Six months after the outbreak of the First World War Pohl was interned. He returned to Germany in 1919, where he became director and chief engineer of the A.E.G. Turbine Works in Berlin. More than thirty papers, published for the most part in *Elektro-Technische Zeitschrift* and *Elektrotechnik und Maschinenbau* between 1919 and 1938, record the contributions which placed Pohl in the first rank of designers of large electrical machines. He made one of the early experiments in the hydrogen cooling of alternators, running a machine in town's gas in Charlottenburg. By 1938 it had become clear to Pohl that he and his family could not much longer escape Nazi persecution. Through the good offices of friends he was able to get away safely to England and was joined by his wife and son. Prof. William Cramp was instrumental in securing the appointment of Pohl to the staff of his department in the University of Birmingham.

The third phase of Pohl's career was to prove no less fruitful than the first two. He brought to his teaching a wealth of practical experience, and he had the power to transmit his ideas. The British Thomson-Houston Co. retained him as a consultant, and it was not long before contributions from his pen began again to appear in the *Journal of the Institution of Electrical Engineers*. This time, inductor alternators and the behaviour of magnetic material in machines claimed much of his attention.

At the time of his retirement from the University of Birmingham Pohl was serving as a consultant in relation to the power supply for the synchrotron which was then under construction, and here again he made a significant contribution.

The outstanding quality of all Dr. Pohl's work is its clear physical insight. Although nearly all his papers involve some mathematical analysis, it is in the originality of his physical concepts that his genius is demonstrated.

Dr. Pohl had an exceptional endowment of fine qualities. He was a man of complete integrity and liberal philosophy. His intellectual distinction he carried lightly, for he possessed a keen and subtle sense of humour which he not infrequently turned against himself. He was musical, a great reader of literature, and he had a critical appreciation of art. Perhaps his most endearing quality was a wonderful capacity for friendship with children. No one could have a more staunch friend, and countless people stand in his debt for help freely given. Pohl was almost too acutely conscious of human suffering and it might be said of him that the sharp distress of the world sometimes pressed upon his keen intellect and sensitive mind to the point of pain. Those who knew Pohl recognized in him a quality of intellect, sympathy, and understanding which is supremely rare.

JAMES GREIG

NEWS and VIEWS

Directorship of the London School of Economics and Political Science :

Sir Alexander Carr-Saunders, F.B.A.

SIR ALEXANDER CARR-SAUNDERS retires as director of the London School of Economics and Political Science at the end of the year, a post he has held since 1937 when he succeeded Sir William (now Lord) Beveridge. There have been only five directors of the School since the beginning in 1895, all of them men of great distinction and breadth of experience, and the present director takes his place as by no means the least distinguished, nor the least successful, of the five. He read zoology at Oxford, but his interests in demographic and social studies led him to accept the offer of the Charles Booth chair of social science at Liverpool in 1923. Since then his contributions to the advancement of social studies and his public services generally have been numerous. He has guided the London School of Economics through what has been perhaps its most difficult period. He found for the School a happy war-time home at Peterhouse, Cambridge, and he leaves it re-established in London, a smooth-running and harmonious institution with an international standing higher than ever before. At the same time, he has been a tireless traveller and an indefatigable worker in the cause of higher education in the Colonies. He was chairman of the two Commissions which led to the creation, first of the University of Malaya, and then of the new University College of Rhodesia and Nyasaland, Salisbury. It is hoped that he will continue to preside over the Inter-University Council for Higher Education Overseas and to give the new universities overseas the benefit of his wise and experienced counsel.

Sir Sydney Caine, K.C.M.G.

SIR SYDNEY CAINE, who succeeds Sir Alexander Carr-Saunders, is well equipped for the task; he brings to his new post an almost unique experience in administration and financial affairs. He is no stranger to the London School of Economics, since he graduated there with great distinction in 1922, and he has served for many years both on the Court of Governors of the School and on the University of London Board of Studies in Economics. Nor is he a stranger to university administration, since he has been a very successful vice-chancellor of the University of Malaya since 1952. Between 1923 and 1952 he built up a high reputation as a Civil servant, first as an inspector of taxes, then for many years in the Colonial Office, and finally in the Treasury. He has served as Financial Secretary in Hong Kong, as financial adviser to the Colonial Secretary, and as head of the Treasury Delegation in Washington. Since he went to Malaya, though giving up a career as public servant, he has not cut himself off from public affairs. He has been concerned with the problems of confederation in the West Indies, and he is at present acting as economic adviser to Mr. Marshall, the Chief Minister in the new administration in Singapore.

Directorship of the Waite Institute, Adelaide :

Prof. J. A. Prescott, C.B.E., F.R.S.

PROF. J. A. PRESCOTT retired from the directorship of the Waite Agricultural Research Institute of the University of Adelaide at the end of January. He had held the Waite chair of agricultural chemistry since 1924 and the directorship of the Institute since 1938. Between 1929 and 1947 he was also chief of the Division of Soils of the Commonwealth Scientific and Industrial Research Organization. For his work in Australian pedology and his studies in agricultural climatology, Prof. Prescott has achieved an international reputation; and on his retirement the University conferred on him the title of professor emeritus.

Dr. James Melville

DR. JAMES MELVILLE, director of the Grasslands Division of the New Zealand Department of Scientific and Industrial Research since 1952, has succeeded Prof. Prescott as director of the Waite Agricultural Research Institute, Adelaide. His interests are broad, but have been concerned particularly with pasture growth and quality in relation to animal production.

New Television Transmitting Station at the Crystal Palace, London

THE first regular daily television service in the world was started from the Alexandra Palace Station of the B.B.C. on November 2, 1936, and with the exception of a break during the war period, this station has provided the service for the London area since that date. On March 28, however, this service was taken over by the new television transmitting station at the Crystal Palace, where the partially completed permanent tower is a notable landmark in south London. A technical description of the new station is contained in a paper presented by Messrs. F. C. McLean, A. N. Thomas and R. A. Rowden at a meeting of the Institution of Electrical Engineers on April 4. The station is planned to have ultimately an effective radiated power of 500 kW., in accordance with the allocation made at the European Broadcasting Conference at Stockholm in 1952. It was decided, however, that the station should open with a power of about 200 kW., but that the building and the power plant should be planned so as to facilitate raising the output to the higher value in the future. A second paper, read at the Institution of Electrical Engineers meeting referred to above, by Messrs. V. J. Cooper and W. J. Morcom (of Marconi's Wireless Telegraph Co., Ltd.) described in detail the television transmitting equipment, which is designed to operate in two parallel chains to ensure the maximum reliability in service.

The station building is buried below the terrace on a two-acre site at the Crystal Palace, and incorporates two vision transmitters of 15 kW. and two sound transmitters of 4 kW., with provision for raising these to 50 kW. and 12 kW., respectively, when necessary. The aerial system consists of eight tiers of dipoles erected around a self-supporting tower, which is tapered to a height of 440 ft. (134 m.) above ground-level, and will later be surmounted by a parallel-sided structure for a further 250 ft. (76 m.) to carry the aerial systems for future transmissions in higher-frequency bands. For the transmission of programmes between Broadcasting House and Crystal Palace, a distance of 9 miles (14 km.), two coaxial cables of 0·975 in. (2·5 cm.) diameter have been provided, for direct transmission between the terminals without intermediate equipment. The cables and their associated terminal equipment are designed for transmission in either direction, since it is proposed to use the Crystal Palace as a pick-up point for television outside broadcasts and carry the signals by the cable to the Broadcasting House switching centre for connexion to the main television network. Full details of this cable link and of its performance are given in a third paper presented at the meeting by Dr. A. R. A. Rendall and Mr. S. H. Padel, of the B.B.C. staff.

Preliminary field-strength measurements made around the Crystal Palace site have confirmed the original theoretical expectations that the population within the service area will be 1·5–2·5 millions greater than the number hitherto served by the Alexandra Palace station. The outer coverage in Kent, Surrey and Sussex is much improved, while only the area immediately surrounding Alexandra Palace and some districts to the north of London experience a decrease in field-strength. Although these areas still receive an adequate service, a minority of viewers may need better receiving aerials.

Future of Colour Television in Britain

AT a meeting of members of the International Radio Consultative Committee, held in London on April 5, Sir Ian Jacob, director-general of the British Broadcasting Corporation, discussed the problem of colour television, with particular emphasis on conditions in Great Britain and the work and future plans of the Corporation. He began by pointing out that the present television programme will soon be capable of being received by 97 per cent of the British population and that there are at present six million television receivers in the hands of the public or, in other words, that 40 per cent of the population have receivers in their homes. The Corporation is conducting a series of technical tests on the N.T.S.C. system of colour television developed by the American radio industry and adopted by the Federal Communications Commission for public use in the United States; for these tests the system has been adapted to the British 405-line television standards, and the object is to determine whether the system gives a satisfactory colour picture without being degraded to any noticeable extent as a black-and-white picture on an existing receiver. The results so far indicate the possibility of a compatible system on 405 lines, and thus it may be feasible eventually to transmit a colour programme on the Band I frequencies that are at present being used and on the Band III ones which are reserved for a future second programme. If, however, a compatible system is not possible, then the only hope for colour television in Britain is to use different transmissions on Bands IV and V frequencies, and this will involve setting up completely new transmitter networks on frequencies which, from the technical point of view, are less favourable; it is not a prospect to be relished.

Turning to the question of reception, Sir Ian pointed out that, besides the technical problems, there are economic and social factors which must inevitably weigh heavily on any decision by the Government with regard to the development of colour television. He is not convinced that a colour receiver has yet been developed, even in the United States, which is satisfactory for large-scale production. The cost of such receivers still seems to be prohibitively high, and the present economic situation is such that the Government wants to restrict home demand and to limit capital expenditure. Sir Ian doubts if all the information is yet available to arrive at any national policy for colour television; but he put in a special plea that the representative bodies of the various countries of the world should keep in close touch with one another so as to secure the greatest possible amount of international standardization.

Institute of Wood Science

IN view of the widespread interest in the technical aspects of wood, it has been felt for some time that there is a need in Great Britain for a national body with the avowed object of advancing scientific knowledge of wood and allied subjects, and as a result of a number of discussions held during the past year an Institute of Wood Science has been formed, with Mr. David D. Irvin, deputy chairman of the Timber Development Association, Ltd., as chairman of the Council and honorary secretary of the Institute. The main purpose of the Institute is "to advance the scientific, technical, practical and general knowledge of persons interested in the study of wood and allied subjects", and it is proposed to interpret this in the broadest possible sense. Thus, besides the study of the anatomy and chemistry of wood, etc., the words ". . . and allied subjects" are intended to include such subjects as wood adhesives, the chemistry of preservatives, pulp, woodworking machinery and similar matters which involve wood indirectly. An immediate objective of the Institute is to start a journal, and Prof. A. R. Gemmell, of the University College of North Staffordshire, has been appointed as editor.

The Institute intends to concern itself directly with education in timber technology or wood science, and ultimately it hopes to become the examining body in at least the senior examinations in this subject. Other aims and activities include the organization of meetings, lectures and excursions, co-operation with other bodies having similar objects and the establishment of branches in various parts of Britain. The various grades of membership of the new Institute will be as follows: fellows (who will be entitled to use the letters F.I.W.Sc. after their names); associates (A.I.W.Sc.); certificated members; ordinary members; junior members; and patrons. The conditions for associateship include the higher certificate of the Timber Development Association, Ltd., or the appropriate certificate of the Institute, or, at the discretion of the Council, a university degree in science, and also three years of experience in wood science; fellowships will be granted to associates at the discretion of the Council. The main condition for certificated membership is the third-year certificate of the Timber Development Association, Ltd. The subscription (which will include receipt of the journal) will be 3 guineas a year for fellows, associates and ordinary members; 2 guineas a year for certificated members; and 1 guinea a year for junior members. Firms, associations or corporations may become patrons by supporting the Institute financially, as also may individuals if they wish to subscribe more than the normal membership fee. Further information can be obtained from the honorary secretary of the Institute, c/o the Timber Development Association, Ltd., 21 College Hill, London, E.C.4.

Higher Technological Education in London and the Home Counties

THE seventh annual report of the London and Home Counties Regional Advisory Council for Higher Technological Education, covering the year ended August 31, 1955 (pp. 40; from the Council, London; 1956), welcomes the Minister of Education's remark to the annual conference of the Association of Education Committees that he would not allow local feelings to spoil higher technical education, and points out that the Council's limited experience so far of planning courses in particular subjects regionally has not been discouraging. In several instances, two or more authorities have jointly examined a known industrial demand and achieved a significant economy with greater efficiency. At the annual meeting of the Council, Sir Hugh Linstead criticized the Minister's proposal to upgrade some twenty or thirty colleges and doubted particularly the possibility of providing even fifteen hundred additional technologists a year from the existing colleges and the possibility of properly staffing and equipping as many as twenty or thirty colleges at the higher level; these criticisms and the subsequent discussion are summarized in the report. The Council has appointed Mr. L. C. Wooder to undertake a research project into the distribution of courses of higher technological education in the region, including an industrial survey of the region, surveys of technical education, communications in relation to the situation and 'catchment' areas of colleges and population trends, and a comparative study of those factors in relation to the distribution of courses. The Council has also recommended to local education authorities which are in membership that a college should not initiate a sessional course of higher technological education unless it has every reason to suppose the course will continue to the end of the session and that if, owing to unforeseen circumstances, the course is terminated before the end of the session, the college should arrange for students to complete the course elsewhere with a minimum of inconvenience to the student. Figures supplied by the Minister of Education for full-time degree and higher diploma students in technical colleges over the three years 1952–55 indicate a marked increase in those attending higher diploma courses in engineering, and the number working for M.Sc. or Ph.D. (internal) degrees during the period rose from 59 to 116. The numbers of students for internal degrees fell from 1,641 to 1,369 and for external degrees from 761 to 544.

Parliamentary and Scientific Committee: Report for 1955

THE annual report for 1955 of the Parliamentary and Scientific Committee (pp. 22; from the Committee, 31 Palace Street, Westminster, London, S.W.1; 1956) provides the usual convenient record of the activities of the Committee during the year, including a list of addresses given to the general committee. Particular attention is given to problems connected with higher technological education and scientific man-power. During the second reading of the Agricultural Research Bill on December 13, representations regarding the present organization of veterinary research were made on behalf of the Committee by Mr. A. J. Champion, its joint honorary secretary, and by Mr. M. Philips Price, and further consideration will be given to this subject by the Committee this year. In view of the alarm expressed by several organizations as to the effect of the higher postal rates for scientific journals and publications, a questionnaire is being sent to all scientific organizations affiliated to the Committee to permit an assessment of the general position with a view to a formal and more detailed statement. During the passage through Parliament of the Rating and Valuation (Miscellaneous Provisions) Bill, the views of the scientific bodies were brought to the notice of the Government, and because of dissatisfaction about the rating position, expressed at a meeting of the Committee on July 12, it was agreed to prepare a comprehensive report for the Government on the rating position of research associations and scientific societies.

Expenditure on Government Information Services

A WHITE Paper on "Government Information Services: Statement showing Estimated Expenditure, 1955–56" (Cmd. 9591. Pp. 4. London: H.M.S.O., 1955; 4*d.* net) gives the expenditure on home services as £2,245,100, compared with £2,333,600 in 1954–55, and on overseas services as £10,495,950, compared with £10,231,700. Of this sum, £741,150 is carried on the Central Office of Information's Vote, of which £150,250 and £156,250 are for the Air Ministry and the War Office, respectively; these two Departments account for £246,700 and £359,850 of the total, respectively. Estimated expenditure for the National Savings Committee (£277,200) and the Road Fund of the Ministry of Transport and Civil Aviation (£213,000) also exceeded £200,000. Of the Overseas Estimate, £4,755,000 is on account of the B.B.C. External Services as grant-in-aid from the Post Office, £1,757,400 as Foreign Office grant-in-aid to the British Council and £2,289,800 on behalf of the Foreign Office, including the German Section. £538,800 goes to the British Council for the Colonial Office, and a further £381,700 for the Commonwealth Relations Office, while expenditure on behalf of the Colonial Office and the Commonwealth Relations Office is estimated as a further £259,800 and £494,700, respectively.

Scottish Field Studies Association: Report for 1955

THE annual report of the Scottish Field Studies Association for 1955 records the progress the Association has made under difficult conditions and indicates what could be achieved if the Association had a centre of its own. During the year the number of students who attended the Field Studies Centre at Garth showed a considerable increase over the previous year, while groups under their own staff attended from a number of schools and university departments. During this year six courses at Garth are planned as follows: May 18–21, outdoor art; August 11–18, introduction to plant ecology; August 18–25, grasses, sedges and rushes; September 7–14, mosses and liverworts; September 14–17, autumn birds; and September 21–24, higher woodlands. The difficulties at Garth, which is primarily organized as a Youth Hostel Association Centre, prevent the development of the Association's activities; and it has now been decided that, when money becomes available, the Glencoe area has considerable advantages of hill and sea, moor and crags, for botanists, geologists, zoologists and others and that a centre should be established there. Particulars about the courses may be obtained from the honorary secretary and treasurer, B. W. Ribbons, Department of Botany, The University, Glasgow.

Populations of House-Mice

SOME observations with house-mice have been carried out at the University of Wisconsin by R. L. Strecker under the guidance of John T. Emlen, jun. (*Scient. Amer.*, December 1955). The investigators first wished to find out whether the mice lived in compact communities or drifted about at random among the college buildings. Trappings showed that the mice were content to live within a narrow range so long as they had plenty of food and shelter. Limiting the population's food supply revealed that, as a food shortage approached, migration from the colony increased sufficiently to 'tap off' mice as quickly as new ones were born. Reproduction apparently continued normally and the remaining population showed no unusual features with regard to sex or age composition. In a further series of experiments the food supply was drastically limited, but the mice were prevented from escaping. As starvation approached, reproduction stopped completely. These investigations on house-mice show that the determining factors in population studies can be examined individually. They should lead eventually to a clearer picture of the parts played by various influences on the abundance and scarcity of animals.

A Flowering Inhibitor in *Kalanchoe*

RECENT experiments with *Kalanchoe blossfeldiana*, by W. W. Schwabe (*Ann. Bot.*, 20, 77, 1; 1956), indicate that a flowering inhibitor may be produced by long-day exposures. He has shown that single long days intercalated between numbers of short days have a positive inhibitory effect on flower initiation and are not merely ineffective. The inhibitory effect expressed as the number of inductive cycles annulled is approximately additive, provided the long days are interspersed with short days, but not if several long days are given consecutively. On the average, one long day is capable of annulling the flower-promoting effect of about 1½–2 short days. To a first approximation, flower numbers in *Kalanchoe* increase exponentially with the number of inductive cycles given—up to at least twelve short days. The inhibitory effect of long days interspersed with short days also fits an exponential curve; that is, the inhibition is roughly proportional to the amount of previous photo-periodic induction. A light break of as little as thirty seconds duration given in the middle of a long dark period is as inhibitory as a long day. If followed by a long dark period the inhibition of an intercalated long day is almost completely neutralized; a long dark period preceding it has no such effect. These results have been interpreted as due to the interaction of a flowering inhibitor with a reaction leading to flowering. A mechanism involving competitive inhibition of an adaptively formed enzyme has been described as a possible example of the kind of reaction which could account for the results presented.

The National Museum of Wales

THE forty-eighth annual report (1954–55) of the National Museum of Wales is a record of steady non-spectacular but important work. Although plans for the much-needed building extensions are still in abeyance, valuable discussions have taken place regarding the proposed new department to illustrate the special industries in Wales. The Welsh Folk Museum deals with rural industries; but the Council considers it urgent that the history of industries and their present practices should be included in the Museum. Especially is this the case in a technological age and when material and information are being lost almost week by week. As usual, the staff have taken their full share of extra-mural activities within the Principality as, for example, the keeper of geology as president of the South Wales Caving Club taking part in negotiations with the view of preserving a cave threatened by quarrying, and the keeper of botany continuing his researches on atmospheric pollens and spores.

Iron and Steel Institute: Forthcoming Meetings

THE eighty-seventh annual general meeting of the Iron and Steel Institute will be held at the Royal Institution (Albemarle Street, London, W.1) and at the offices of the Institute (4 Grosvenor Gardens, London, S.W.1) during May 16–17. On the evening of May 15 a Bessemer Centenary Lecture will be given at the Royal Institution by Mr. James Mitchell, past president of the Institute, and on the morning of the next day the new president, Dr. H. H. Burton, will take office and deliver his presidential address. Following this, Prof. N. F. Mott, Cavendish professor of experimental physics in the University of Cambridge, will give the ninth Hatfield Memorial Lecture, his subject being "The Fracture of Metals".

During June 5–14 the Institute will hold a special meeting in France in association with the Chambre Syndicale de la Sidérurgie Française and the Société Française de Métallurgie. During June 5–11 the meeting will be in Paris, and the remainder of the time will be spent on three excursions to iron and steelmaking areas in eastern, central or northern France. Further information on the meetings can be obtained from the Secretary of the Institute at 4 Grosvenor Gardens, London, S.W.1.

Fifth World Power Conference, Vienna

THE Fifth World Power Conference will be held in Vienna during June 17–23, the headquarters of the

Conference being at the Konzerthaus, Lothringerstrasse 20, Vienna III. The theme of the Conference is "World Energy Resources in the Light of Recent Technical and Economic Developments", and the technical programme will consist of six divisions, at which the following topics will be discussed: the present status and development of power production and utilization in individual countries; the preparation and conversion of fuels; utilization of primary sources of energy; purification of waste water and exhaust gas in the production and use of energy; international co-operation in the production and use of energy. Short excursions will be available in Austria during the Conference, and afterwards a number of extensive tours of hydroelectric stations, power stations, etc., have been arranged in Austria, Yugoslavia, Italy and southern Germany. Further information is available from the various national committees, the British one being at 201–202 Grand Buildings, Trafalgar Square, London, W.C.2. Otherwise, all inquiries should be addressed to the Oesterreichisches Nationalkomitee der Weltkraftkonferenz, Vienna I, Schwarzenbergplatz 1.

Chemical Society: Officers

Officers of the Chemical Society have been elected as follows: *President*, Prof. E. L. Hirst; *Vice-Presidents*, Sir Ian Heilbron, Sir Cyril Hinshelwood, Prof. C. K. Ingold, Dr. W. H. Mills, Sir Eric Rideal, Prof. W. Wardlaw, Prof. E. D. Hughes, Prof. E. R. H. Jones, Dr. R. P. Linstead, Prof. H. W. Melville, Prof. M. Stacey and Sir Alexander Todd; *Honorary Treasurer*, M. W. Perrin; *Honorary Secretaries*, Dr. L. E. Sutton, Prof. F. Bergel and Dr. J. Chatt; *New Members of Council*, Prof. R. M. Barrer, Prof. A. G. Evans, Prof. L. Hunter, Dr. G. W. Kenner, Prof. B. Lythgoe, Dr. A. Maccoll and L. A. K. Staveley.

University of Birmingham

The following have been appointed Research Fellows in the University of Birmingham: D. B. Holt (physical metallurgy) and Dr. G. Hübscher (pharmacology). The University has received from Ciba, Ltd., of Basle, a Ciba research scholarship for three years of £700 a year for the work and training of a graduate in the techniques of organic chemistry; in the first instance, the scholar will work on the synthesis of new halogen-containing organic compounds under the direction of Prof. M. Stacey. A grant of £900 has been made by the Electrical Research Association to the Department of Electrical Engineering of the University for the continuation of research work on electric discharges in liquids.

Announcements

Dr. J. S. D. Bacon, senior lecturer in biochemistry, University of Sheffield, has been appointed head of the new Department of Biochemistry at the Macaulay Institute for Soil Research, Aberdeen, as from September 1 next.

The forty-first annual conference of the Textile Institute will be held in Blackpool during May 22–25, the subject for discussion being "New Yarns and Fabrics". Further information can be obtained from the Institute at 10 Blackfriars Street, Manchester 3.

An international conference on "Nuclear Reactions", organized by the Nederlandse Natuurkundige Vereniging, will be held in Amsterdam during July 1–7. Among the topics discussed will be elastic and inelastic scattering, capture and photo reactions, stripping and pick-up reactions and fission. Further information can be obtained from the secretary of the conference committee, Dr. S. A. Wouthuysen, Zeeman Laboratorium, Pl. Muidergracht 4, Amsterdam (*C*).

A symposium on the methods, materials and processes involved in the uses of high temperatures in science and industry, organized jointly by the Stanford Research Institute and the University of California, Berkeley, will be held in Berkeley during June 25–27. Further information can be obtained from Dr. Nevin K. Hiester, manager of the Chemical Engineering Section, Stanford Research Institute, Menlo Park, California.

The Second World Congress on Fertility and Sterility, sponsored by the International Fertility Association, will be held in Naples during May 18–26, the scientific sessions being held at the Palazzo Mostra di Oltremare and the inaugural session at the Castel Angioino. Simultaneous translations in English, French, Spanish and Italian, with the use of head-phones, will be available. In addition to the human aspects of the subject, there will be sessions on animal fertility and sterility. Further information can be obtained from Prof. G. Tesauro, Faculty of Medicine, University, Naples.

A symposium on molecular structure and spectroscopy will be held in the Department of Physics and Astronomy of the Ohio State University during June 11–15. Both the interpretation of molecular spectroscopic results as well as methods for obtaining them will be discussed. The Joint Commission on Spectroscopy of the International Union of Pure and Applied Physics and the International Astronomical Union will meet concurrently with the symposium. Further information can be obtained from Prof. H. H. Nielsen, Department of Physics and Astronomy, Ohio State University, Columbus 10, Ohio.

The annual meeting of the Société de Chimie Physique will be held in Paris during May 29–June 1, when the subject, "Superficial Reactions of Gases on Metals", will be discussed. All the fundamental phenomena affecting the development and structure of thin films formed by gases on metal surfaces will be considered, with the exception of pure absorption and catalysis. Further information can be obtained from Prof. G. Emschwiller, École Supérieure de Physique et Chimie, 10 rue Vauquelin, Paris 5e.

The Fourth International Congress on Fruit Juices will be held in the Killesberg Park, Stuttgart, during May 28–June 2, the organizers being the Zentralverband der Sussmost- und Obstgetrankein-Industrie. The Congress is under the auspices of the International Federation of Fruit Juice Producers (Paris), and official representatives of the food and health services of twenty countries, as well as industrialists, exporters and importers, will be attending. The programme will include fifteen general reports and forty-four special reports, dealing with problems both from the point of view of medicine and hygiene and from the scientific, technical and practical angles; international questions referring to production, conditioning, sales and outlets will also be considered. Further information can be obtained from the office of the Congress at Bachstrasse 26, Bonn Rhein, Germany.

MATHEMATICAL EDUCATION IN SOUTH ASIA

AN international conference on mathematical education, with special reference to countries of South Asia, was held in Bombay at the Tata Institute of Fundamental Research during February 22–28, under the presidency of Prof. K. Chandrasekharan, of the Tata Institute.

In his presidential address, Prof. Chandrasekharan suggested that difficulties in South Asia stem from an inadequate recognition of the value of creative intellectual activity as part of the drive towards prosperity, and put forward five proposals to enable the creative scientist to come into his own. First, the gifted research worker must be given a suitable working atmosphere and adequate financial support; this might be done through a system of research contracts set up by a government and administered by a national committee for mathematics. Secondly, the facilities for training students in advanced mathematics must be increased, by providing graduate schools for advanced study. Thirdly, courses of study must be integrated, and the present very rigid examination system radically modified. Fourthly, the teaching staff in colleges must be reinforced, and the teacher must be given more leisure, more encouragement, and more opportunity for keeping in touch with new ideas in mathematics. Fifthly, suitable text-books must be provided; if need be, a national text-book committee, equipped with adequate funds, must be set up to seek out competent authors and induce them to write the much-needed books. Finally, the school course must be revised and rendered more elastic, since creative mathematics cannot prosper fully unless the foundations are firmly laid in the schools.

Invited addresses were given to the conference by Prof. A. D. Alexandrov (U.S.S.R.), Prof. E. Bompiani (Italy), Prof. T. A. A. Broadbent (United Kingdom), Prof. G. Choquet (France), Prof. H. Freudenthal (The Netherlands), Prof. E. Marczewski (Poland), Prof. A. Oppenheim (Malaya), Prof. M. H. Stone (U.S.A.), Prof. Hsio-Fu Tuan (China). Some of these addresses dealt with the problems of mathematical education arising in the speaker's country, and described methods which are being used in the solution of such problems. Others dealt with the application of new methods in psychology to mathematical education, with new ideas in teaching arithmetic, and with the best way of beginning the teaching of geometry.

For detailed discussion of special questions, and particularly of the five points raised in the presidential address, members of the conference were divided into three working groups, one for the school stage, one for the bachelor's or master's degree stage, and one for the postgraduate stage. Each group discussed, in its relevant context, the aim of mathematical education, the ideal scope and content of the course, the recruitment, maintenance and training of the teacher, the mode of selection of the students at the higher levels and maintenance of such students, and the necessary facilities and equipment to be required. It was concluded that, at the schools, instruction should be closely related to the needs, the capacity and the interests of the pupil, and an integrated and simplified course, including some statistics as well as the traditional subjects, should be offered. At the universities, the degree course should meet the requirements of society in general, should train those intending to teach mathematics in schools or universities, and should begin the training of the professional mathematician. The postgraduate training should fit students for research and for the teaching of advanced mathematics; here a course of lectures in the most recent developments is essential, though no formal examination should be imposed. Examinations at the lower levels should be more flexible, no student should be asked to stake his whole career on the results of a single examination, written examinations should be supplemented by oral examinations and by an evaluation of the student's total performance; where possible, teachers should participate in the examination of their own students. The provision of text-books, scholarships, summer schools and seminars, and research contracts, was examined in detail, and specific recommendations were made.

The working groups reported interim progress to plenary sessions, from which further instructions were received. Finally, the findings of the working groups were incorporated in a set of resolutions presented to and unanimously adopted by the last plenary session of the conference. This session further resolved to set up a permanent small committee for mathematics in South Asia, under the chairmanship of Prof. Chandrasekharan; this committee would bring the resolutions of the conference to the notice of responsible educational authorities in South Asia, and press for the rapid implementation of these proposals. It is hoped to have on this committee representatives of India, Pakistan, Burma, Ceylon, Indonesia, Malaya-Singapore, and Thailand.

No member of the conference could fail to be impressed by the vast problems confronting the teachers of mathematics in South Asia, the urgent needs of the students in those countries, and the enthusiasm of their teachers. Perhaps because of the magnitude of the problems, the conference worked harmoniously, national and sectional interests seldom being allowed to intrude. But above all, the success of the conference was due to the knowledge, skill, organizing ability and driving force of the president, Prof. Chandrasekharan. He focused attention on special problems, induced strong and definite resolutions, and left no doubt in members' minds that great efforts will be made to have these proposals accepted and implemented by the appropriate authorities in the countries of South Asia.

SCIENCE AND PEOPLE

IN his presidential address to the American Association for the Advancement of Science at Atlanta on December 28, 1955, Dr. Warren Weaver, of the Rockefeller Foundation, examined the influence of science on people (*Science*, 122, No. 3183).

Science, he said, has impressively proved itself to be a powerful way of dealing with certain aspects of our experience. These are, in general, the logical and quantitative aspects, and the method works superbly for linear and stable physical problems in two or three variables. The physical universe seems to be put together in such a way that this scientific approach is exceedingly successful in producing a good, workable, initial description. With that kind of solid start, physical science can then safely proceed to elaborate more sophisticated theories.

How far these methods will be successful in the world of living things is not yet known. The successes to date are very impressive. One feature after another that previously seemed to fall in a special 'vital' category has usefully yielded to biochemical or biophysical attack. As yet only a beginning has been made. How far the logical quantitative method will succeed here, it would be rash to forecast, although the prospects seem extremely promising.

Small beginnings at extending the scientific method into the social sciences have been made. In so far as these fields can be dealt with in terms of measurable quantities, they seem to present closely intercoupled situations that can very seldom usefully be handled with two or three variables and often require very many—for example, W. Leontief's input–output analysis of the United States economy deals with some fifty variables and regrets that it does not handle more. Science has, as yet, no really good way of coping with these multivariable but non-statistical problems, although it is possible that ultra high-speed computers will inspire new sorts of mathematical procedures that will be successful in cases where the effects are too numerous to handle easily but not numerous enough or of suitable character to permit statistical treatment. If we try to avoid the many-variable aspect of the social sciences by using highly simplified models of few variables, then these models are often too artificial and over-simplified to be useful. The statistical approach, on the other hand, has recently exhibited—for example, in the stochastic models for learning—new potentialities in the field of human behaviour.

It is not at all necessary that the particular analytical techniques of the physical sciences be forced upon biological or social problems with the arrogant assumption that they can and should make unnecessary other types of insight and experience. During the Second World War, an extremely useful collaboration was developed, known often as operations analysis, in which reasoning of a mathematical type was applied to certain aspects of very complicated situations, but with no expectation that judgment, experience, intuition, or a vague sort of general wisdom would be displaced or superseded—rather only that these would be aided by whatever partial light could be furnished by quantitative analysis.

An important characteristic of science is its incapacity to be impractical. The most far-reaching discoveries and the most widespread useful applications flow regularly out of ideas that initially seem abstract and even esoteric.

Science presents the kind of challenge that attracts to it young men and women who tend to have a rather high degree of a certain kind of intelligence. But scientists are not special creatures: they are people. The great majority of scientists have the same distribution of moral and intellectual characteristics as other educated people.

If scientists are human, so also is science itself. For example, science does not deserve the reputation it has so widely gained of being based on absolute fact, of being wholly objective, of being infinitely precise, of being unchangeably permanent, of being philosophically inescapable and unchallengeable. There seem still to be persons who think that science deals with certainty; it deals with probabilities.

The ablest scientists themselves realize the postulational and provisional character of science. Perhaps not so widely recognized or accepted is the extent to which the development of Western science has been influenced by the general nature of Græco-Judaic culture, including especially the standards, arising within that tradition, of what is interesting and important.

The previous comments concerning general characteristics of science suggest that science is a very human enterprise, coloured by general ideas, changeable as any human activity must be, various in its possible forms, and a common part of the lives of all men.

Even the impressive methods that science has developed involve only improvement of procedures of observation and analysis that the human race has always used.

These comments do not support the concept of science as some sort of super creed. This point of view does not justify the notion that science is so special as to be unique, as well as so curious as to be incomprehensible. This does not depict scientists as strange creatures who are in one sense so objective, judicial and precise as to be incredible, and in another sense so apart from life as to be selfish and sinister. This does not set up quantitative analytical Western science as the only valid way in which man may approach and interpret experience.

These descriptive comments picture science as the servant of man, not his master; and as a friendly companion of art and of moral philosophy.

The lack of general comprehension of science is dangerous both to science and to the public, these being interlocked aspects of the common danger that scientists will not be given the freedom, the understanding and the support that are necessary for vigorous and imaginative development.

TECHNICAL INFORMATION SERVICES IN EUROPE

UNDER the title "Technical Information Services in Europe", the European Productivity Agency of the Organization for European Economic Co-operation has published a report on the second meeting of technical information officers, held in Frankfurt-am-Main during May 2–6 last (from the Organization, 2 Rue André Pascal, Paris, 16e). The conference, which included delegates from twelve different countries, was intended to give participants an insight into the functioning of the technical information services which are an integral part of the German Productivity Centre at the Rationalisierungskuratorium der Deutschen Wirkschaft in Frankfurt, and the first section of the report outlines the services, activities and relations of this body. It is a private organization which has as its aim the rationalization of the entire German economy and increased productivity, and in this task representatives of science and engineering, of industry, and of trade, commerce and crafts, of trade unions and of government agencies are co-operating with it. It is organized both on a regional and on a subject basis and has a priority programme covering those fields where it is believed that an actual increase in productivity can be achieved. In referring to information services, Dr. Magnus, of the board of directors of the Rationalisierungskuratorium, emphasized the importance of bringing the inquirer to formulate his question correctly. Besides describing the activities of the information service, which up to April 1955 had answered more than ten thousand questions, this section of the report gives a brief account of information and documentation in Germany, including the work of the German Society for Documentation, the Association of German Engineers, and the Association of German Mechanical Engineering Firms and the Prior Art Information Service, Treuhandstelle Reichspatentamp, Berlin, and also of the operation in Germany of the Documents Exchange Scheme of the Organization for European Economic Co-operation.

The second section of the report deals with the activities and projects of the European Productivity Agency in the field of technical information, including Dr. A. King's address on the general policy of the Agency, which emphasizes that, to be efficient, the Agency must concentrate on work that is better done on an international basis than nationally. Much of the Agency's work next year will be devoted to encouraging relations between the various national productivity centres and to services which may be of use to them all. Dr. King also emphasized the importance of forward thinking on productivity matters and of providing a forum for the discussion of particular topics which may be only germinating in the minds of men in individual countries, so that understanding can be reached which will lead to international attack on a problem and accelerated action. In this connexion he said that the Agency had appointed a working party to consider automation and particularly its human relations and economic problems and the relation of the whole subject to the future industrial pattern of European countries. The Agency has also been considering the economic switch-over which the introduction of automation will entail. Dr. King thought that in the past technical information work was too narrowly conceived and that its main task is to serve industry with the object of increasing productivity levels. He urged a closer relation between management and human relations and labour, on one hand, and the technological and technical information activities, on the other, and that at present not enough technical information of the less technological type is disseminated. Much new work is required of a research, survey and experimental nature in connexion with the social problems of technical innovation.

Suggestions made at the conference for future activities included the recommendation that the work of national technical information centres be undertaken for the general needs and within the scope of the overall productivity programme of the countries and productivity groups, and that the European Productivity Agency should intensify its relations with international vertical organizations and other international organizations in the field of technical information. The Agency was also asked to consider extending its system, in co-operation with the national technical information services, to include problems on management, human relations and similar topics. It was agreed that national technical information services should be encouraged to adopt the field officer method of providing technical information and that, while the Documents Exchange Scheme should not be regarded as a substitute for personal, organizational or multilateral contacts, which the national centres should encourage, it should include as much unpublished material as possible; in general, such centres should help each other with material which it is difficult to obtain. The conference suggested that those countries in which 'technical information days' have not yet been organized should make use of this idea, and that the European Productivity Agency and national centres should use every kind of publicity and publication to spread knowledge about technical information services.

COMMONWEALTH FUND, NEW YORK

ANNUAL REPORT FOR 1954–55

THE thirty-seventh annual report of the Commonwealth Fund, New York, covering the year ended June 30, 1955*, records that forty-one Fellows were appointed to hold fellowships in the United States during 1955–56, and another sixteen will be in residence on second-year extensions, bringing the total of Fellows elected since 1925 to 729. This figure includes 550 scholars appointed on applications through universities in Great Britain, and 139 Civil servants, of whom forty-two were from the Home Civil Service and ninety-seven from the Dominion and Colonial Services. It also includes thirty-three scholars from Western Europe in a programme of Continental fellowships which was started in 1952. Of the total appropriation of 3,469,972 dollars during the year, 1,954,071 dollars was in the field of medical education, including research in educational environment and procedures and the evaluation of educational experiments, while a further 210,000 dollars was appropriated for advanced medical fellowships, and 206,650 dollars for advanced nursing education, including twenty-one new and five extended awards as well as block grants to five institutions. Appropriations of 887,926 dollars for medical research were voted for nine projects, four of which were for studies of organism-environment interaction, two for studies of integrative processes within the organism and three for studies in basic biology. Ten other projects have continued to receive support from appropriations voted in previous years. Grants for experimental health services totalled 137,750 dollars, including a renewed grant of 118,250 dollars to the Hunterdon Medical Centre, New Jersey, to underwrite, for the next three years, two-thirds of the cost of the Centre's community mental-health programme and 19,500 dollars to the Tennessee Medical Foundation for operating costs during the next two months. The Fund's publication programme continues to provide, in conjunction with the Harvard University Press, for the publication of manuscripts and books emanating from projects supported by the Fund in the field of health.

The appropriations for medical education went to twenty-seven institutions, six appropriations being grants for new projects and ten being extensions of assistance to old ones, while fifteen institutions received assistance from previous appropriations. Four of the new projects reflect the increased collaboration between medicine and social science. A three-year grant to Yale University was for an experimental graduate training programme in the social aspects of medicine, in which the experience with health and medicine will come in the last two years of a four-year period of graduate study. At the University of North Carolina a two-year grant will permit further joint research between the Division of Health Affairs and the Institute for Research in Social Science. A two-year grant to the Bureau of Applied Social Research of Columbia University and the University of Pennsylvania School of Medicine is to extend to the study of the influence of environmental factors upon the educational process which occur in the last four years of medical studies. The University of Kansas received a two-year grant for the Department of Psychology to pursue an investigation of the doctor–patient relation in a rural community, and a two-year grant to the University of Florida is to assist in making the Health Centre, which includes the Medical School, an ntegral part of the University.

---

* Commonwealth Fund Thirty-seventh Annual Report for the Year ending June 30, 1955. Pp. vii+46. (New York: Commonwealth Fund, 1955.)

A grant to the Western Reserve University, Cleveland, was to complete the revision of the entire curriculum of the four years of the medical school, and a separate grant was made for the continuing evaluation of the students' progress. Terminal grants were made to the University of Colorado School of Medicine for the support of the General Medical Clinic at Denver General Hospital and for research in education and the cure of patients. An appropriation was made to McGill University for a two-year survey of the medical curriculum, and a new programme of instruction at the Department of Pediatrics, Harvard University, will emphasize growth from the pre-natal period to physical maturation, preventive aspects of pediatrics, and service and teaching, which include the home and community environment and effective patient–doctor relation.

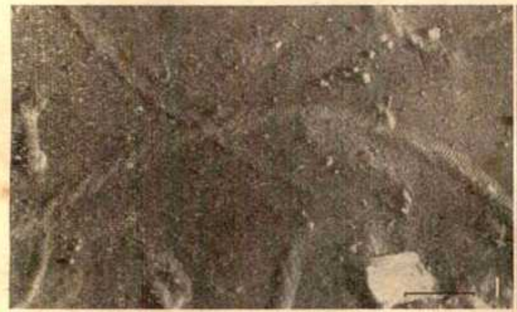
HELICAL NATURE OF THE COLLAGEN FIBRIL

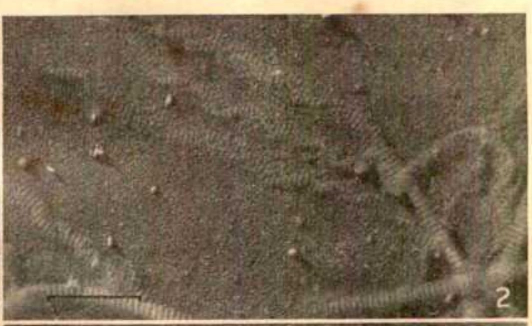
By Dr. R. REED, Miss M. J. WOOD and Dr. M. K. KEECH
Department of Leather Industries, Department of Medicine,
University of Leeds

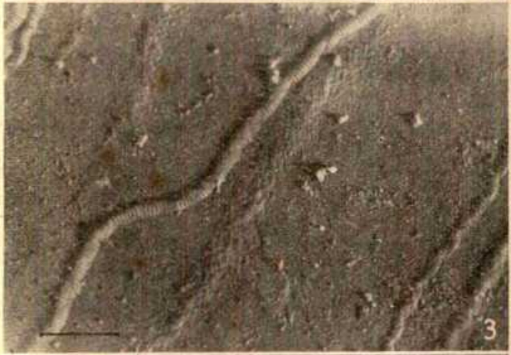
THE electron microscope has provided much information regarding the structure of the collagen fibril. In the main, however, it has proved difficult to correlate such information with that obtained from other fields of investigation. X-ray diffraction studies have indicated that the polypeptide chains in collagen are likely to have a helical configuration, and recent work[1] has been concerned with deciding which particular form of helix best fits the diffraction data. We wish to report certain electron microscope findings which indicate a helical arrangement of filaments, that is, *bundles* of polypeptide chains, within the collagen fibril.

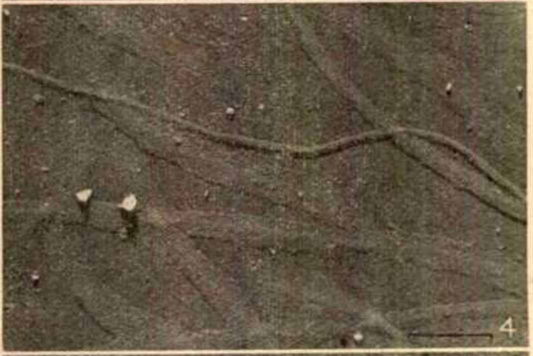
During a study of the effect of various reagents on collagen fibrils over the pH range 1–12·5 and at temperatures between 25° and 37° C., we have observed that the fibrils often assume a helical form (Figs. 1–8). This helical form usually occurs in the early stages of reaction; with longer reaction times this may disappear and more deep-seated changes may set in, characteristic of the reagent used. The fibril, in assuming the helical form, is transformed into a series of structures with tapering ends, to which we give the name 'helical tactoids'. These vary in length from 6000 to 12,000 A. and are 1000–2000 A. in width (Figs. 1, 2, 5, 8 and 10). They tend to become shorter as the pH value increases, and their angle of inclination to the fibril axis varies with the degree of swelling. The helix determined by these tactoids has no preferred direction, for both left-hand and right-hand forms are observed; Fig. 1 shows that both forms may occur at different regions in a single fibril. Subdivision of the helical tactoids into thinner structures may occur, especially under highly acid conditions, and this process does not radically affect the characteristic cross-striations, which lie at right-angles to the fibril axis (Figs. 2 and 3). With increasing subdivision of the helical tactoids, the fibril loses cohesion, becomes flattened and ultimately gives rise to a system of crossed filaments (Figs. 3, 6 and 7), in which the outlines of the cross-striations can still be seen. Depending on the conditions, the filaments vary in width over the range 200–500 A. With some reagents at pH 2·0, and which produce rapid swelling and disintegration, the fibrils become ribbon-like, with a raised helical centre portion (Figs. 4 and 6). Helical tactoids have also been observed[2] during the thermal shrinkage of tanned collagen fibrils (Fig. 9).

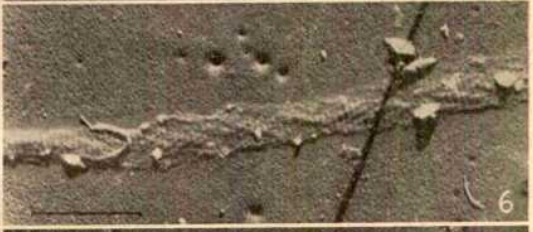
In view of these observations, we propose a fibril architecture based on two regular helical systems of filaments. These helices, determined by the filaments, are equivalent in every respect, except that one is right-hand in direction, the other left-hand. Such cross-helical systems are often observed in the electron microscope (Figs. 3, 6 and 7) and are also suggested by the presence of both helix directions within the same fibril. To account for the helical tactoids, we propose that certain filaments in the cross-helical array are more sensitive to heating and chemical reagents than are the other filaments. In other words, we suggest that helical tactoids indicate a cross-helical array of filaments, but which are not all of the same chemical composition. At the level of organization of the polypeptide chains, coiled-coil configurations based on a unit of three polypeptide chains have recently been proposed[1] by workers in the field of X-ray diffraction. As Cowan, McGavin and North[1] have pointed out, however, if one accepts such a three-chain unit, the chemical data lead directly to the concept of mixed-chain types. For one of the three chains in the unit to contain the sequence —pro—hypro—gly— to any large extent (as indicated by sequence studies[3]), from the number of residues available it must also contain the bulk of the prolyl and hydroxyprolyl residues. Thus these workers imply that the collagen fibril is built from a unit of three polypeptide chains, one of which is different in chemical composition from the other two. While agreeing that mixed polypeptide chains are likely to exist within the collagen fibril, we do not think that such a unit would account for the electron microscope observations. Indeed, we consider that the fibril architecture is better accounted for in terms of 'filaments' of differing chemical composition. Thus we suggest that various types of filaments are present, each based on different chain types, any single filament, however, containing

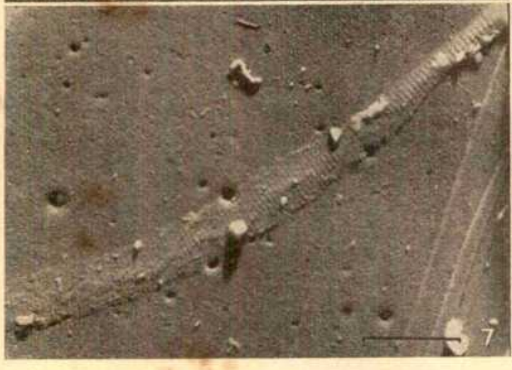












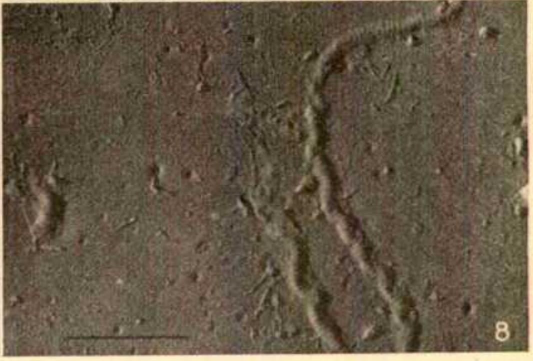


Fig. 1. Human dermal collagen fibrils after 30-min. exposure at 25° C. to an aqueous solution, pH 1·8, containing 1 per cent periodic acid and 1 per cent sodium chloride. Note left and right helices within the same fibril

Fig. 2. Same as Fig. 1, showing subdivision of helical tactoids

Fig. 3. Same as Fig. 1, showing system of crossed filaments in which the cross-striations can still be seen

Fig. 4. Different sample of same substrate used in Figs. 1–3 after 5-min. exposure at 37° C. to a 1 per cent solution of performic acid. Highly swollen, ribbon-like fibrils with raised, helical central portion and reduced band spacing

Fig. 5. Same substrate after 1-hr. exposure at 25° C. to a 10 per cent solution of calcium chloride at pH 7·0

Figs. 6 and 7. Effect of dichloracetic acid on a collagen fibril showing crossed helical system of filaments with persistence of cross-striations

Fig. 8. Same substrate as Figs. 6 and 7 after 18-min. exposure at 37° C. to a carbonate buffer solution, pH 10·4

chains of the same type. Thus, if the chains rich in hydroxyproline were concentrated into one filament, and the series of hydroxyproline-rich filaments were regularly distributed along the fibril, the helical tactoids could arise by such filaments becoming detached from the cross-helical array. This would mean (referring to Fig. 10) filaments rich in hydroxyproline along the lines *A–A*. To account for the observed subdivision of the tactoids, there must also be thinner but similar filaments along the lines *B–B*, for example. The details of the distribution of the filaments within the fibril, however, still need to be worked out. Thus it is not impossible that the fibril consists of two equally large strands, which spiral around each other. In turn, this cross-helical system is spirally covered, either in the left- or right-hand direction, with filaments which contain the bulk of the chains rich in hydroxyproline. By removal of the spiral covering of filaments (rich in hydroxyproline) the fibril would assume a two-strand form, similar to that in Fig. 9.

Such filaments, rich in hydroxyproline, could account for the preferential liberation of hydroxyproline-rich fragments from disks of collagen, when alkaline buffer solutions are forced through them[4]. Further, they might also determine the stability of the fibril by being more sensitive towards heat than the other filaments, as indicated by the work of Gustavson[5], who has shown that the hydroxyproline content of various forms of collagen fibrils is an index to their thermal stability.

Since the cross-striations of the collagen fibril tend to persist in spite of radical subdivision of the helical tactoids (Figs. 2, 3, 6 and 7), the material of which they are built possibly differs in chemical composition from that removed from the fibril when the tactoids are formed. Thus to some extent the tactoids appear to be separate from the cross-striations, as though the latter acted as restraints for the filaments within the fibril and were a means of controlling their lateral cohesion[6].

The proposed model affords a basis for investigating the physical and chemical behaviour of collagen fibrils. Swelling and shrinkage could be interpreted in terms of the cross-helical systems of filaments moving with respect to each other, so that they made a larger angle with the fibril axis (see Fig. 10). This process would lead to a stretching of the characteristic cross-striations and, at the same time, bring them closer together. Such effects have been observed both in native collagen and in tanned collagen fibrils (Figs. 4, 7 and 9). Keech[7] has shown that collagenase breaks down collagen into short lengths with tapering ends (tactoids). The helical model now proposed for the fibril offers a more rational explanation for such tactoids than the flat type illustrated in Fig. 32*c* of her paper.

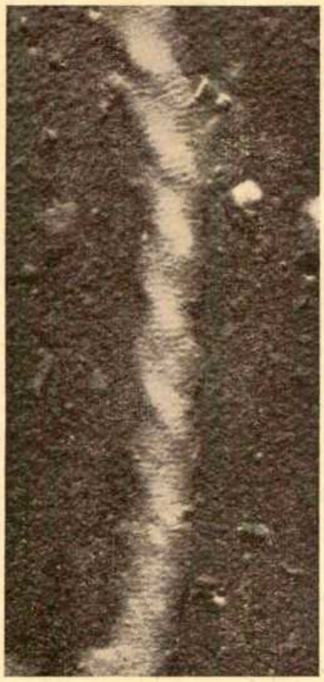

Fig. 9. Oil-tanned collagen fibril from chamois leather after 1-min. heating in water at 70° C., showing helical tactoids and contraction of the band spacing

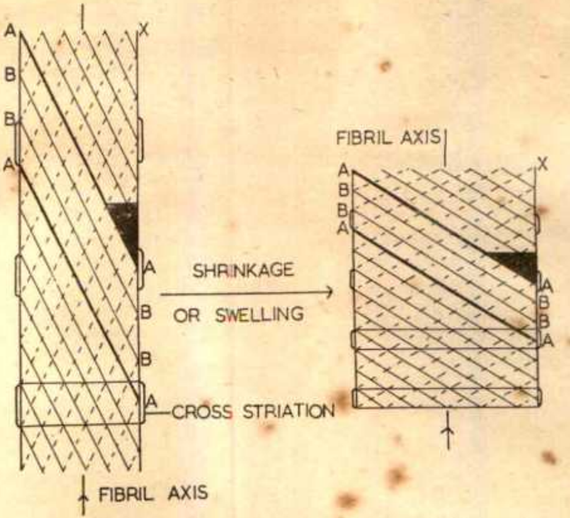

Fig. 10. Diagrammatic representation of the cross-helical system within a collagen fibril, showing helical tactoids *AAAA*. Also change of angle *AAX* and reduction in band-spacing with swelling and shrinkage,

Helical structures in the collagen fibril have been observed previously by electron microscopists. Wyckoff[8] published, but did not comment upon, a cross-helical structure in the fibril following the action of dilute acetic acid. Stromberg and Swerdlow[9] consider that the cross-striations follow a helical course around the fibril. Further, they relate this helical form to an additional one, similar to that described by us. However, as we have pointed out, and indeed, as Fig. 7 in their paper illustrates, the cross-striations appear to be independent of the helical tactoid structures. These workers studied only aqueous suspensions of collagen, whereas our work has included a wide range of reagents acting both on native and on tanned collagen.

To summarize, we feel that an architecture of the collagen fibril based on a system of filaments in a regular cross-helical array best accounts for the helical structures observed in the electron microscope. Moreover, since the polypeptide chains in the fibril probably differ in chemical composition, these filaments, that is, bundles of polypeptide chains, may consist almost entirely of one type of chain, and thus they also may differ in their total chemical composition. We wish to emphasize that the helical structures based on filaments are observed at the electron microscope level of organization, and that it is still possible for the filaments to have an internal coiled-coil structure, as suggested by the X-ray diffraction studies[1]. Oxytocin as Stimulator for the Release of Prolactin from the Anterior Pituitary

AT the present time there is reason for believing that the suckling stimulus influences the mammary gland in two ways. First, there is abundant evidence (see ref. 1 for review) that suckling or other conditioned stimuli can evoke the release, from the neurohypophysis, of oxytocin, which in turn causes contraction of myoepithelial cells associated with the alveoli, resulting in ejection of stored milk from the alveolar tissue (the milk-ejection reflex). Secondly, according to the theory proposed by Selye[2], the suckling stimulus causes release, from the anterior hypophysis, of prolactin which participates in the maintenance of secretion and of the functional integrity of the mammary alveolar tissue. These facts suggested to us that the primary effect of impulses reaching the brain as a result of the application of the suckling stimulus is to activate the neurohypophysis, causing the release of oxytocin, which, by a route that need not be discussed here, reaches the anterior pituitary and stimulates the latter to release prolactin.

In order to test this hypothesis we utilized a phenomenon, first demonstrated by Selye[2], who showed that in the lactating rat the involution of mammæ, the suckling of which was prevented by the surgical removal of the nipples, was markedly retarded, provided suckling of other intact nipples in the same animal was continued. Selye's contention that this was due to the release of prolactin in response to the suckling of the intact nipples was later confirmed by Williams[3], who was able to retard mammary involution in non-suckled lactating mice, by injections of prolactin.

We have therefore studied the effects of injections of oxytocin on the course of mammary involution in lactating rats from which the litters were removed at the fourth day of lactation. Fig. 1 shows a section (*b*) from an abdominal mammary gland of a lactating rat whose litter was removed at the fourth day of lactation and which thereafter received 1·0 international unit of oxytocin intraperitoneally, three times daily, until autopsy at the thirteenth day. Comparison with the section (*a*) taken from a control rat which, instead of oxytocin, received injections of saline, shows that mammary involution was markedly retarded by the oxytocin treatment. These results are typical of most animals of the three short series (see Table 1) receiving oxytocin which we have so far studied.

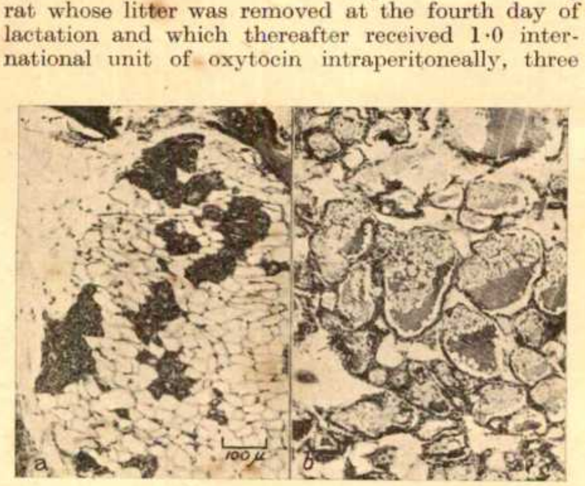

Fig. 1. Abdominal mammary glands of lactating rats from which the pups were removed at the fourth day, the mother thereafter receiving intraperitoneal injections of (*b*) 1·0 I.U. oxytocin three times daily for nine days, and (*a*) 1·0 ml. saline three times daily for nine days. Sections were cut at 7 μ, stained with hæmatoxylin-eosin and photographed at the same magnification

Table 1

Group	Dose of oxytocin	Number of animals	Mean alveolar diameter with stand. error (μ)
A	controls	5	15·5 ± 1·8
B	0·25 I.U. three times daily	4	24·6 ± 7·5
C	1·0 I.U. three times daily	4	65·7 ± 10·6
D	1·5 I.U. three times daily	4	57·9 ± 15·6*
B + C + D		12	49·4 ± 8·1

* This high standard error is due to the fact that one rat completely failed to respond.

Estimations of the mean alveolar diameter have been made measuring a hundred alveoli selected at random from each rat. The figures so obtained are summarized in Table 1. It is clear that in accord with the sections illustrated in Fig. 1, the alveoli of the treated rats were significantly larger than those of the untreated controls, particularly in the groups receiving the highest two dose-levels. This difference may be ascribed to the continuing secretion in the glands of the treated animals in contrast to the absence of secretion and subsequent general involution in the mammæ of the untreated animals. The results of these preliminary experiments indicate that the release of prolactin (and perhaps other anterior-pituitary hormones concerned in lactation) can be stimulated by treatment with oxytocin.

That neurohypophysial hormones may be concerned in the control of adenohypophysial secretion has been suggested previously by a number of workers (see Scharrer and Scharrer[4] for review; also Martini and Morpurgo[5], and Shibusawa *et al.*[6]) but principally with relation to the secretion of adrenocorticotrophic hormone.

Even if our results are fully confirmed in further experiments which are now under way, they cannot in themselves be taken as proof that the release of prolactin is evoked by oxytocin under conditions of normal suckling, but they are nevertheless consistent with this view. We consider it unlikely that the results are due to a direct effect of oxytocin on the mammary gland, because Bradley[7] in this laboratory has recently found that prolactin, alone of a number of anterior and posterior-pituitary principles tried, including oxytocin, had a localized lactogenic effect when injected intraductally into the mammæ of suitably prepared rabbits.

Absorption of Vitamin B_{12} from the Rat Intestine

MANY animal tissues contain specific protein-like substances that combine with vitamin B_{12}. The availability of the vitamin in this bound form when given by mouth to animals depends on the origin of the binding material. Homologous bound forms are fully available, whereas a similar preparation from a different species may not be[1].

To study the importance of 'binding' in the absorption of vitamin B_{12}, it was necessary to use animals deprived of that portion of their gut where binding substances are located. The following technique was devised to allow the retention of a small amount of labelled vitamin B_{12} in a section of the small intestine for some hours without its being influenced by secretions from the stomach or duodenum. Stock-colony rats weighing approximately 200 gm. were starved overnight. The abdomen was opened under ether anæsthesia to expose the small intestine. A ligature was made near the ileo-cæcal junction and the intestine was cut above it. A similar ligature was placed near the lower end of the duodenum and the intestine cut just below this point. The cut portion of intestine was washed through with 100 ml. warm saline to remove any binding materials remaining in it and the lower end was tied off. ½ ml. saline, containing the dose of labelled vitamin B_{12} with or without binding material, was introduced from a syringe fitted with a blunted needle into the upper end of the cut intestine, which was tied off as the needle was withdrawn. The gut was replaced and the incision closed.

The whole operation was performed as rapidly as possible with the minimum of handling in order to prevent damage to the absorbing surfaces and to retain as nearly as possible a normal blood supply to the cut segment. The rats were kept without food in a glass metabolism cage for 20 hr., and urine and fæces were collected on filter paper. At the end of this period, the rats were anæsthetized and about 5 ml. of blood withdrawn from the heart. The tied-off portion of intestine was carefully removed and dissolved by heating with 25 ml. of 4 N sodium hydroxide. The liver was treated similarly, and the remaining carcass and the filter paper containing urine and fæces were separately ashed. The ash was prepared for measurement of radioactivity by dissolving in the minimum volume of concentrated hydrochloric acid. All samples were counted in a liquid counter (20th Century Electronics type $M6$). Since this type of counter responds to traces of radioactivity present in animal tissues, corresponding organs from untreated rats were submitted to the same procedure and the counts subtracted from those of the experimental rats for calculation of the amount of vitamin B_{12} absorbed. Except for the carcass, these counts were not significantly above background. Typical figures for the radioactivity of the carcasses, after subtracting the background count (19 counts/min.) were: untreated rat, 16 counts/min.; rat given free labelled vitamin B_{12}, 54 counts/min.

Each rat received 60 mμgm. vitamin B_{12} labelled with cobalt-57 (2·5 mc./mgm.), either alone or with the precise amount of the test preparations required to combine with this quantity of the vitamin. The substances given with the vitamin were a saline extract of rat stomach, a crude intrinsic-factor preparation from pig pyloric mucosa ('Bendogen', G.E.A., Copenhagen) and a preparation of the binding protein isolated from 'Bendogen' by continuous electrophoresis[2]. The radioactivity found in the tissues of each rat, calculated as vitamin B_{12}, is shown in Table 1.

Table 1. ABSORPTION FROM THE RAT INTESTINE OF 60 mμgm. VITAMIN B_{12} GIVEN ALONE AND WITH PREPARATIONS OF BINDING PROTEINS. Values given in mμgm. vitamin B_{12}

Binding preparation given with the vitamin B_{12}	Exp. No.	Tissues examined				Total amount of vitamin B_{12} absorbed
		Liver	Carcass	Urine and fæces	Gut and contents

Binding protein from 'Bendogen'	1	—	—	—	—	—
	2	0·2	1·4	1·5	44·4	3·1
	3	—	—	—	—	—
	4	0	1·4	0·3	44·5	1·7
	Mean	0·1	1·4	0·9	44·5	2·4

* This figure is unaccountably low.

The content of labelled vitamin in the blood was too low to be detected by our equipment. Only small amounts reached the liver or were excreted, and the greatest proportion of the absorbed vitamin was found in the carcass. An appreciable proportion of the free vitamin was absorbed in 20 hr., but this is not surprising in view of the large dose, 0·06 μgm., that had to be used to obtain significant counts. However, addition of the saline extract of rat stomach doubled the amount of vitamin absorbed. This effect was not observed with 'Bendogen', which is known to facilitate the uptake of vitamin B_{12} in human pernicious anæmia. In fact, 'Bendogen' decreased absorption, and the binding protein prepared from it behaved similarly. Our direct demonstration of the effect of binding substances on the uptake of vitamin B_{12} is in agreement with indirect findings of other authors. Chow *et al.*[3] measured in gastrectomized rats the fæcal excretion of orally administered labelled vitamin B_{12}, and showed that intrinsic factor preparations from the pig hindered the absorption of vitamin B_{12}. Similarly, Latner[4] cites unpublished observations by Clayson, Latner and Schofield showing that human gastric juice and pig intrinsic factor inhibited absorption of vitamin B_{12} in the normal rat. Watson and Florey[5] found that rat stomach extract decreased the fæcal excretion, that is, increased the absorption of vitamin B_{12} in gastrectomized rats. Although in our own experiments vitamin B_{12} was given at more than the physiological level, the results are in agreement with those quoted above, in that rat stomach extract helped the absorption of the vitamin, whereas its absorption was hindered by a foreign binding protein.

Whatever the mechanism by which the rat stomach extract facilitated absorption of vitamin B_{12}, we showed by ultrafiltration[6] that the vitamin had entered into combination with protein. It was similarly bound to the crude and purified pig pyloric preparations, but these hindered absorption. From these experiments it is not clear whether or not combination with a binding protein is the essential part of the mechanism of absorption of vitamin B_{12}. If it is, clearly the protein concerned is not the same for all animals. If the binding process is not essential, then some other factor necessary for absorption must also differ from one type of animal to another. Finally, it may well be that several factors, including perhaps the binding protein, are involved, and that any or all of these may be peculiar to a given species or group of animals.

These experiments were made possible by a generous gift of radioactive vitamin B_{12} from Dr. D. L. Mollin, of the Postgraduate Medical School of London.

Infectivity of Ribonucleic Acid from Tobacco Mosaic Virus

In their experiments with bacteriophages, Hershey and Chase[1] have shown that only the nucleic acid component plays a part in the intracellular multiplication. There are also indications that in simple viruses containing ribonucleic acid the nucleic acid plays a dominant part in the infection. Thus, experiments with tobacco mosaic virus have shown that the protein can be changed chemically without affecting the activity and the genetic properties[2]; recently, it was even found[3] that part of the protein can be removed from tobacco mosaic virus without destroying the activity.

We have now obtained evidence that after complete removal of the protein, the ribonucleic acid itself is still infectious.

The protein was extracted from tobacco mosaic virus with phenol by a procedure elaborated by Schuster, Schramm and Zillig (to be published). After a short treatment at low temperatures, a preparation of ribonucleic acid is obtained which has a high molecular weight during the first few hours but depolymerizes in the course of time. Its physical properties will be described elsewhere.

A solution of 10 per cent tobacco mosaic virus in 0·02 *M* phosphate buffer of *p*H 7·3 is shaken for 8 min. at 5° C. with an equal amount of water-saturated phenol. The aqueous phase which contains the ribonucleic acid is separated by centrifugation, and the process of extraction with phenol is repeated at least twice for 2 min. The phenol is then extracted by ether from the aqueous phase. The whole procedure is carried out at 5° C. and takes about 50 min.; it is followed immediately by testing the infectivity.

For that purpose, five to ten plants of *Nicotiana glutinosa* with five leaves each were inoculated with a diluted solution of the ribonucleic acid, and an equal number of plants with a standard solution of tobacco mosaic virus. The number of local lesions produced by ribonucleic acid and tobacco mosaic virus are compared in Table 1. It is found that 10 μgm. of ribonucleic acid produces about the same number of lesions as does 0·2 μgm. tobacco mosaic virus. The infectivity of the ribonucleic acid preparation is thus about 2 per cent of that of the native virus.

Table 1. Comparison of the Infectivity of Ribonucleic Acid and Tobacco Mosaic Virus in 0·1 *M* Phosphate Buffer

	Ribonucleic acid		Tobacco mosaic virus	
*p*H	μgm./ml.	lesions	μgm./ml.	lesions
6·1	10	153	0·09 0·8	95 445
7·3	10	815	0·27	1,048
7·3	1	524	0·05	795
7·5	10	998	0·27	685

The following experiments, the results of which are collected in Table 2, have been carried out to show that the infection is due to the nucleic acid rather than to contamination of the ribonucleic acid with native virus.

(*a*) In the ribonucleic acid solution protein was not detectable by chemical methods (Schuster, Schramm and Zillig, unpublished work); thus the amount must be less than 0·4 per cent of the ribonucleic acid content. By serological methods (complement fixation) it was shown that the ribonucleic acid contains less than 0·02 per cent of native tobacco mosaic virus protein.

(*b*) Treatment of both the ribonucleic acid and tobacco mosaic virus with normal rabbit serum (concentration 3×10^{-3}, applied for 10 min. at 4° C.) somewhat reduces the infectivity. There is no significant further reduction if the ribonucleic acid is treated with the same amount of tobacco mosaic virus antiserum, whereas with antiserum the infectivity of the virus itself is almost completely destroyed.

(*c*) Incubation of the stock solutions of ribonucleic acid (0·3 per cent) and tobacco mosaic virus (0·06 per cent) with 2 μgm. per ml. of ribonuclease at 4° C. for 10 min. reduces the activity of the ribonucleic acid to 0, whereas that of the virus remains almost unaffected.

(*d*) The sedimentation constant of the ribonucleic acid is 12–18 *S*, compared with 180 *S* for tobacco mosaic virus. We have centrifuged the stock solution of ribonucleic acid for 30 min. at 50,000 rev. per min. and found the supernatant liquid to be only a little less active than the original solution. If the solution of the virus is treated in the same manner, the activity of the supernatant liquid is very low.

(*e*) The ribonucleic acid is known to be unstable; and, as would be expected, its infectivity is much reduced after 48 hr. at 20° C., whereas that of the virus is much less affected.

These experiments show that protein, if present at all, is only there in very small amounts and does not resemble closely the native protein of tobacco mosaic virus. We are thus led to conclude that the infectivity is due to the nucleic acid itself.

Table 2. Comparison of Ribonucleic Acid (10 μgm./ml.) and Tobacco Mosaic Virus (0·27 μgm./ml.) in 0·1 *M* Phosphate Buffer of *p*H 7·3
(Infectivity expressed as lesions per 30 leaves)

	Ribonucleic acid	Tobacco mosaic virus
Normal	488	629
With normal serum	180	117
With antiserum	145	0
With ribonuclease	0	473
After ultracentrifugation	367	31
After 48 hr. at 20° C.	2	130

The infectivity of the ribonucleic acid preparation is about 0·1 per cent of that of the same amount of ribonucleic acid contained in native tobacco mosaic virus. Whether this relatively low value is due to a large inactive fraction of the ribonucleic acid preparation, or to low efficiency of the mechanism of infection, has still to be determined.

Studies on the combination of the ribonucleic acid with proteins are being carried out and may elucidate the connexion between our findings and the reactivation experiments of Fraenkel-Conrat and Williams[4], of Lippincott and Commoner[5], and of Hart[6].

We are much indebted to Prof. H. Friedrich-Freksa for helpful discussions, to Mr. R. Engler and Dr. H. Schuster for their co-operation, and to Miss A. Kleih for assistance.

A detailed account of this work will be published in the *Zeitschrift für Naturforschung*.

A Possible Mode of Action of 2 : 4-Diamino-5-phenyl-thiazole Hydrochloride (Daptazole or Amiphenazole)

SOME pharmacological properties and clinical uses of 2 : 4-diamino-5-phenyl-thiazole hydrochloride (daptazole or amiphenazole) have been previously considered elsewhere[1]. It often appears to exert a mild respiratory stimulant effect in both unnarcotized and narcotized patients and animals. It has been used clinically as a buffer to depressed respiration in such conditions as pneumonia, asphyxia neonatorum and in the relief of respiratory depression following anæsthesia. It has further been employed in the treatment of barbiturate intoxication (usually in combination with ββ-methyl ethyl glutarimide (*NP*13, megimide or bemegride)) and opiate overdosage, and has been administered in combination with large doses of morphine in the relief of severe and prolonged pain. When used in this latter manner, it has appeared to minimize the onset of tolerance or addiction to morphine. It is effective both orally and parenterally, and has a high therapeutic index (greater than 10). Therapeutic doses (5–50 mgm.) are almost completely devoid of side effects, and large doses (more than 200 mgm.) have been safely tolerated by unnarcotized volunteers. In small doses (20–40 mgm.) it often appears to improve the mental outlook of depressed patients.

The fact that daptazole has such widespread activity and that such large doses have been safely tolerated has suggested that this substance may fit into some fundamental physiological process.

As the structures of daptazole and the thiazole moiety of thiamine (4-methyl-5-hydroxy-ethyl-thiazole) show some similarity and, further, as thiamine appears to be the only substance occurring naturally in the body which contains the thiazole nucleus, experiments were performed in which rats (40–50 gm.) on a thiamine-free diet were given daily intraperitoneal injections of daptazole and the pyrimidine moiety of thiamine (2-methyl-4-amino-5-brom-methyl-pyrimidine dihydrobromide) to see if the combination of these two drugs would produce a substance capable of entering into thiamine metabolism[2].

Table 1

All rats on a thiamine-free diet. 10 animals in each group

Group	Drugs administered (mgm./kgm. intraperitoneally)			Period of adaptation (days)	Onset of thiamine-deficiency symptoms	Reversal by vitamin B_1
	Daptazole	Pyr. B_1*	Frequency			
Control	—	—	—	—	2–3 weeks	+
1	10	2·5	three times daily	7–10	None for 9 weeks	−
2	50	12·5	daily	—	10 days to 2 weeks	+
3	50	—	daily	—	4–5 weeks	+
4	—	12·5	daily	—	3–4 weeks	+

* Pyr. B_1 = 2-methyl-4-amino-5-brom-methyl-pyrimidine dihydrobromide.

Preliminary results (Table 1) indicate that rats, maintained on low doses of these drugs (10 mgm./kgm. daptazole hydrochloride; 2·5 mgm./kgm. 2-methyl-4-amino-5-brom-methyl-pyrimidine dihydrobromide given intraperitoneally three times daily), after a period of adaptation (seven to ten days), showed no signs or symptoms of thiamine avitaminosis nine weeks after the commencement of the treatment, whereas their controls were clearly deficient in thiamine in three weeks and had all died in five weeks.

The results also indicate that the symptoms of thiamine deficiency developed in rats maintained on a thiamine-free diet could be reversed by similar administration of these doses of daptazole and the pyrimidine moiety of thiamine. However, the daily administration of larger doses of daptazole (50 mgm./kgm.) and the pyrimidine moiety of thiamine (12·5 mgm./kgm.) to such rats appeared to bring about a more rapid induction of thiamine avitaminosis which could be reversed by the administration of thiamine. This more rapid onset of thiamine avitaminosis was not produced when either drug was given alone in these larger doses, and indeed the condition of these animals seemed better than that of their control groups. These observations suggest that daptazole may enter into the pathway of processes involving thiamine. This may be one of its modes of action, and could serve to afford some rationale for its wide sphere of clinical and pharmacological actions in apparently unrelated and diverse processes which may be dependent on thiamine.

This hypothesis is now being investigated and a full account will be published elsewhere.

The Leydig-cell Homologue in Certain Teleost Fishes

THE male sex gland of the Craniata is, like other endocrine organs, extremely ancient in origin. It occurs in the Agnatha (for example, *Petromyzon*) and throughout the gnathostome series with relatively little recorded variation except in the Urodela. With the above exception, and another about to be described, the interstitial gland is characteristically composed of aggregations of modified connective tissue cells which occupy interstices between the seminiferous tubules of the testis. These secretory Leydig cells have a generally similar appearance, and exhibit certain common histochemical properties, in both jawless fishes and, for example, man. The interstitial aggregation of Leydig cells may constitute either a permanent secretory unit (as in most mammals) or may be renewed at the end of each breeding rhythm as in seasonal birds[1].

In the latter case, there is an annual development of large lipoidal cholesterol-positive Leydig cells from minute interstitial connective tissue cells. Unless appropriate histological methods are employed, it is impossible to distinguish connective tissue cells from immature Leydig cells. This is generally responsible for the not-infrequent claim in the literature of breeding seasons that interstitial cells were absent at a stated period of the sexual cycle of some particular bird.

In studies of fishes also, Leydig cells have often been said to be absent, or, on the other hand, have not been mentioned at all. The reason for this may sometimes lie in the fact that two strikingly distinct endocrine arrangements occur in the testes of fishes. The first (Fig. 1) is the typical vertebrate interstitial gland (Leydig cell) pattern and is found in common teleosts such as the three-spined stickleback (*Gasterosteus aculeatus*)[2], *Tilapia* spp., and the sprat (*Clupea sprattus*). This arrangement occurs also in the choanate *Latimeria* and in the widely unrelated selachians *Scyliorhinus* and *Chimaera* (unpublished work). The second (Fig. 2) and less-obvious type, arising not in the interstices but in the lobule walls, we now show to occur in the pike (*Esox lucius*), char (*Salvelinus willughbii*), and *Labeo* (sp. ?). Judged by published illustrations[3], it probably occurs in the salmon (*Salmo salar*) as well.

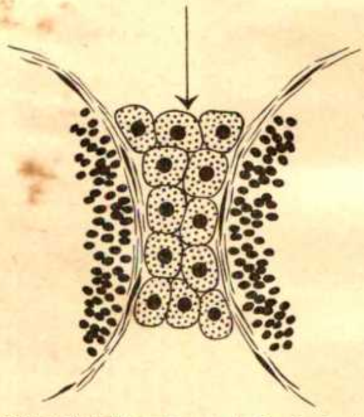

Fig. 1. Typical vertebrate arrangement of endocrine interstitial Leydig cells

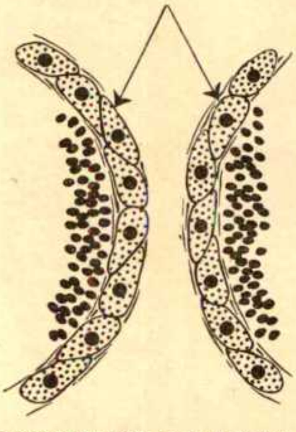

Fig. 2. The Leydig cell homologue in the lobule walls of certain teleost fishes

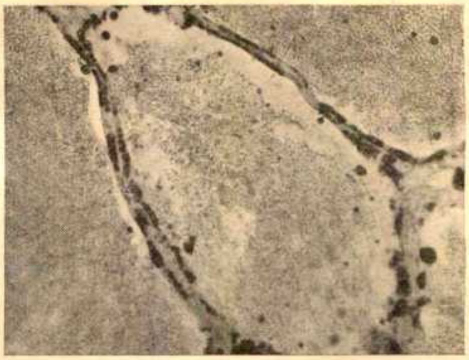

Fig. 3. Lobule boundary cells in the pike (*Esox lucius*) in March. (Formal–calcium fixation, sudan-black colouring at 10μ. × 300)

As is well known, the lobule or crypt wall in the teleost testis is, like the walls of seminiferous tubules in tetrapods, composed essentially of fibroblasts. In both pike and char these, in the absence of a secretory interstitium, become seasonally modified into lipoidal, cholesterol-positive gland-cells similar to the interstitial cells of tetrapods. We provisionally name these 'lobule boundary-cells' (Fig. 2).

The annual boundary-cell cycle is essentially similar to that of the interstitial cycle in seasonal birds. After spermatozoa are shed, the lobule contents metamorphose and the resultant sudanophil material becomes cholesterol-positive. The spent lobules are now bounded by unmodified fibroblasts. These grow, and become lipoidal and cholesterol-positive at about the same time that the sudanophil material within the lobules disappears. It is almost certain that the lobule boundary-cells have the same endocrine function as interstitial Leydig cells. They finally expend their cholesterol at the pre-spawning period in April, after which the cycle begins anew. Most histological techniques permit the loss of vital cytoplasmic lipids from boundary-cells and render them difficult to distinguish from ordinary fibroblasts; but the use of sudan dyes demonstrates their presence with unmistakable clarity (Fig. 3).

However distinct at first sight, the two types of endocrine cells are morphogenetically very similar. In most vertebrates, gonadotrophic influences operate on intertubular connective tissue and produce sexual function. In the few exceptional fishes mentioned above, the influences are on peri-lobular connective tissue, apparently with a similar result. In addition to the typical vertebrate interstitial Leydig cells in the anuran *Rana temporaria*, and in the reptile *Vipera berus*, a few tubule-wall fibroblasts may be modified in much the same way as occurs in pike and char.

In some fishes, however, the phenomenon is constant. The only interlobular elements seen by us have been blood-vessels, lymph spaces and their contents, and during the first few weeks after spawning, what appear to be primary germ cells.

It will be interesting to discover whether the distribution of interstitial Leydig cells on one hand, and the boundary-cells on the other, falls into line with current teleost taxonomy. Both char (family Salmonidae), which has lobule boundary-cells, and the sprat (family Clupeidae), which has Leydig cells, belong to the same order (Isospondyli) as at present constituted.

A more extensive account of the sexual cycle of the pike and further information on the distribution of lobule boundary-cells will appear elsewhere. We are grateful to Prof. H. Brattstrom (Bergen), Messrs. R. S. A. Beauchamp and Humphry Greenwood (Uganda), Prof. J. Millot (Madagascar), and particularly to Mr. G. J. Thompson (Windermere) for helping us to obtain study material.

Proposed Terminology for Wool Follicles in Sheep

The terminology proposed by Wildman and Carter[1] for hair follicle types in Mammalia has been widely used in studies on sheep, although it is in some respects unsuitable for certain other species[2,3]. However, recent workers[4-6] on the histology of sheep skin have independently extended this terminology, but not always consistently, so that confusion has arisen. To overcome this a unified system of terms and symbols for wool follicles in sheep is here proposed. Based on that of Wildman and Carter, with the major division into primary and secondary follicle types, it provides for a recent contribution to the study of the development of the wool follicle, namely, the distinction between original secondary follicles which arise directly from the epidermis, and derived secondary follicles which arise from them by branching[7,8].

The terms and symbols used in the classification of wool follicles into types are set out in Fig. 1 and defined below.

P is primary follicle, and S is secondary follicle as defined by Wildman and Carter[1], and Carter[9].

PC is central P, and PL is lateral P of a trio group as defined by Carter[9] (= P_C and P_L respectively of Fraser[5]).

PCX is member of first-formed PC, PCY is member of later-formed PC, PLx is PL associated with PCX, and PLy is PL associated with PCY. (The symbols X, Y, x and y are used in the same sense as by Wildman and Carter[1], and Carter[9].)

SO is original S, and SD is derived S as defined by Hardy and Lyne[7,8].

SOU is unbranching SO, and SOB is branching SO as defined by Hardy and Lyne[8].

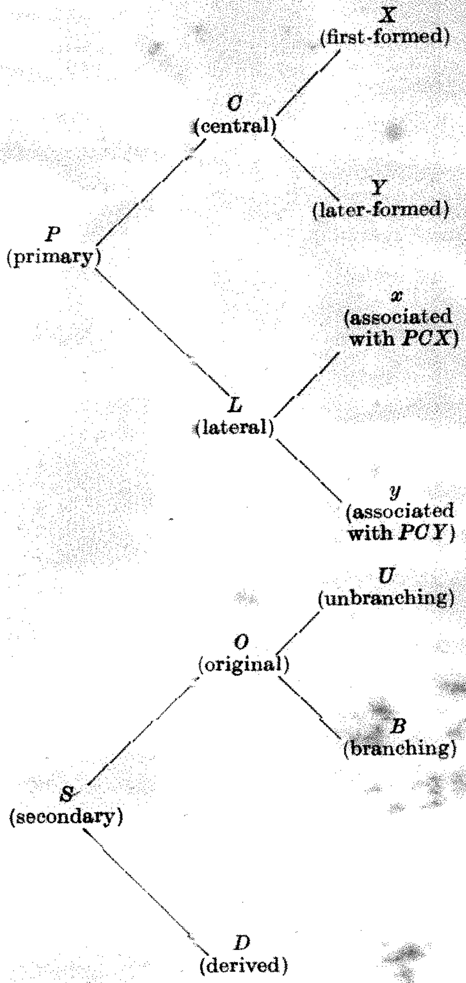

Fig. 1. Key to the classification of wool follicles

Within each follicle type three states of follicle development or activity are distinguished.

i is an incompletely developed follicle at any stage prior to the formation of a keratinized fibre, that is, at any stage from $F1$ to $F5$, as defined by Hardy and Lyne[7,8]. (Carter and Hardy[10] used the symbol p for primary follicles in this state, and s for secondary follicles. Fraser and Hamada[6] used S_U for secondary follicles. Burns[4] referred to two groups of stages of incompletely developed follicles as 'plugs' and 'news'.)

f is follicle containing a fibre, that is, stage $F6$ as defined by Hardy and Lyne[7,8] or any later stage up to and including that in which a fibre has ceased growing but remains in the follicle. (Carter and Hardy[10] used P and S respectively for primary and secondary follicles in this state. Fraser and Hamada[6] used S_F for secondary follicles.)

The symbols for the state of follicles should follow those for follicle types. Different combinations of symbols may be used for different purposes. Thus, while it is frequently necessary only to distinguish P from S, sometimes PC must be distinguished from PL[5,6], and in the early stages of follicle development PCX needs to be distinguished from PCY[8,10]. In any study of follicle development in early postnatal life, Si and Sf must be separated[11,12].

For quantitative work, such symbols have frequently been used for representing numbers of follicles. With the above symbols, any ratio of numbers of follicle types may conveniently be expressed. Thus S/P (or more strictly nS/nP) is the ratio of secondary to primary follicles, while Sf/Pf (nSf/nPf) is the ratio of secondary follicles containing fibres to primary follicles containing fibres.

In the nomenclature described above, terms and symbols which have been found useful for different purposes are combined in a single system in which there are no overlapping categories. Expansion within the system is possible if required. All the symbols except the previously defined X, Y, x and y are mnemonic, and for ease of type-setting, superscript and subscript letters have been avoided.

We would like to thank the following members of the Commonwealth Scientific and Industrial Research Organization for helpful discussions on these proposals: Mr. P. G. Schinckel, Dr. B. F. Short and Dr. K. A. Ferguson, of the Sheep Biology Laboratory, Prospect, Mr. R. H. Hayman, of the F. D. McMaster Field Station, Badgery's Creek, Miss A. G. Culey, of the McMaster Laboratory, and Dr. A. S. Fraser, of the Section of Animal Genetics, University of Sydney.

Ciliary Feeding Mechanisms of Brachiopods

At the suggestion of the late Prof. J. H. Orton, I undertook a comparative study of the ciliary feeding mechanisms of brachiopods, after Richards[1] had reported a new method of ciliary feeding in *Neothyris*, which suggested that the main food and respiratory currents were produced by different methods in different brachiopods. Owing to the difficulty of obtaining diverse living material, it may be some time before the work can be completed and published; a mechanism has been discovered, however, which probably accounts for the differences in the descriptions by Orton[2] and Richards[1] of feeding in *Crania* and *Neothyris* respectively.

In Orton's account of the ciliary feeding mechanism of the inarticulate *Crania*, with spirolophus lophophore, it was shown that the lateral cilia beating across the length of the filaments created the main water current passing through the mantle cavity, the inhalant apertures being lateral and paired and the exhalant anterior and single. The frontal cilia passed food particles to the bases of the filaments and so into the food grooves leading to the mouth.

Richards, in her work on the articulates *Neothyris* and *Terebratella*, with plectolophus lophophores, although agreeing with Orton in the position of the inhalant and exhalant apertures, found that both lateral and frontal cilia beat toward the tips of the filaments, and that the inhalant current entered the lophophoral spaces of the lateral arms against the beat of these cilia. To account for this she was obliged to formulate the hypothesis that the inhalant current was produced by cilia lining the exhalant chamber and the spiral arm. She considered that their action caused a volume of water to be discharged through the anterior exhalant opening, and that to replace this, water was drawn into the inhalant chamber through the lateral inhalant openings. From the spiral arm water was discharged through the inter-filamentary spaces into the exhalant chamber.

Of the articulates, I have so far studied the terebratuloids, *Terebratulina retusa* and *Gryphus vitreus*, and the terebratelloid, *Macandrevia cranium*; of the inarticulates, only *Crania*. In all these, the lateral cilia, beating across the length of the filaments and from the inside to the outside of the lophophoral spaces, create the main water current, which in the adults, whether with plectolophus or spirolophus lophophores, enters laterally and leaves the shell anteriorly. In young stages (*Terebratulina retusa* seen so far) with simple circular lophophore (trocholophus) and with slight anterior indentation (early schizolophus), the inhalant current is single and median, setting into the bell-shaped lophophore, while the exhalant current escapes between the filaments all around, but leaves the shell chiefly laterally and ventrally, for the lophophore lies nearer the brachial than the pedicle valve. As the anterior indentation increases with age, two lateral arms being formed, the median inhalant current becomes divided into two.

The frontal currents in all the species examined are capable of reversal. Small particles are conveyed by the frontal cilia toward the bases of the filaments and eventually reach the mouth; large particles and collections of particles are conveyed to the tips of the filaments and are finally rejected from the shell. In a thick culture of *Chlorella* or other small organisms, the frontal cilia beat toward the tips of the filaments. This reversal of the frontal currents of the filaments appears to be due to reversal of the ciliary beat and not to adjacent tracts of cilia beating in opposite directions as in certain bivalves[3]. Orton[2] observed only the feeding reaction of the frontal cilia of *Crania*, while Richards[1] evidently saw only the rejection reaction of these cilia in *Neothyris* and *Terebratella*. *Neothyris* and *Terebratella* are sufficiently close allies of *Macandrevia* to make it very probable that reversal of the frontal cilia occurs in them as in *Macandrevia*. It is understandable that Orton and Richards failed to see the full behaviour of the frontal cilia, for reversal is not a consistent reaction in the opened animal and on small pieces of lophophore.

Change in direction of beat of the lateral cilia has not been observed, and it is difficult to account for Richards's statement of the direction of their beat in *Neothyris*; but the following observations may have some bearing on this. The lateral cilia sometimes have the appearance of beating somewhat obliquely, as in the ectoproct Polyzoa[4]. Also, in an opened animal, on portions of lophophore and detached filaments, these cilia are frequently more or less inactive and masked by the continuous beat of the long frontal cilia; there is little difference in length of lateral and frontal cilia in brachiopods.

In *Terebratulina retusa*, *Gryphus vitreus* and *Macandrevia cranium*, abfrontal cilia are present on the filaments and these beat continuously toward their tips.

From work now in progress, it would seem that Orton[2] was justified in his general inference from a detailed knowledge of *Crania*, and a limited knowledge of *Gryphus vitreus* (= *Terebratula vitrea*) and *Argiope*, that "the main current through the mantle cavity in brachiopods is produced chiefly by the lateral cilia on the gill filaments". It would also seem probable that reversal of the frontal currents on the filaments will be found in brachiopods generally.

This work was done while holding a Leverhulme Research Fellowship.

Reversal of Mating Preference by Crossing Strains of *Drosophila melanogaster*

Sexual selection may be an important component of the selection pressures determining changes of gene frequency in Mendelian populations, and a number of studies of *Drosophila* have been made with the object of assessing degree of competition for mates (see, for example, refs. 1 and 2) and have led to the conclusion that, while male vigour is an important factor, discrimination and preference between genotypes do occur and seem to be largely female attributes. In an attempt to assess the importance of mating preference as a factor affecting changes of gene frequency in some experimental populations described elsewhere[3], we have come across a phenomenon which, as far as we can discover, has not been reported before.

We wished to test the preference of w/w, w^a/w^a and w/w^a females for w^a or w males in two separate environments (one constant 25° C., the other 25° during the day and 15° during the night). The flies were obtained from stock cultures, the w/w^a females by crossing. Each female to be tested was placed in a food tube with one male of each kind for two days, and her offspring were grown and classified according to genotype of father. Failures were ignored and double matings were scored $\frac{1}{2}$. Three replicate tests gave the combined results shown in Table 1.

Over all the experiments, the two types of male have equal success ($\chi^2_{(1)} = 0{\cdot}3810$, p, $0{\cdot}7$–$0{\cdot}5$); but there is significant heterogeneity within the data ($\chi^2_{(6)} = 18{\cdot}843$, $p < 0{\cdot}01$). All this heterogeneity is associated with the degree of freedom for difference between the w/w^a females and the two homozygous female types ($\chi^2_{(1)} = 13{\cdot}660$, $p < 0{\cdot}001$; residual $\chi^2_{(5)} = 5{\cdot}183$, $p \simeq 0{\cdot}3$), and the difference is in the direction that w/w^a females prefer w males, whereas both w^a/w^a and w/w females prefer w^a males. The respective degrees of preference are about equal: 0·7 of the w/w^a matings were with w, 0·6 of the w^a/w^a matings were with w^a and 0·7 of the w/w matings were with w^a.

Table 1

Environment:	25° C.			15–25° C.			Total		
Successful male:	w	w^a	Total	w	w^a	Total	w	w^a	Total
Type of female									
w/w	7·0	19·0	26·0	10·0	17·0	27·0	17·0	36·0	53·0
w^a/w^a	14·5	14·5	29·0	9·0	19·0	28·0	23·5	33·5	57·0
Total	21·5	33·5	55·0	19·0	36·0	55·0	40·5	69·5	110·0
w/w^a	18·0	10·0	28·0	21·5	8·5	30·0	39·5	18·5	58·0
Total	39·5	43·5	83·0	40·5	44·5	85·0	80·0	88·0	168·0

There is thus a remarkable difference between the mating preferences of the two types of stock female and the females produced by crossing these stocks. We cannot, of course, associate it with the marker locus, for it may be associated with genes or gene complexes anywhere in the chromosome complement. However, the observation that mating preference may be reversed by hybridization, even though the types hybridized have similar preferences, is striking. If such reversal of preference were associated with a single locus or small block of chromatin it could, in certain circumstances, be responsible for a stable polymorphism.

A Simple Potometer for measuring Rate of Water Uptake by Small Seeds

The usual method of measuring rate of water uptake by seeds is to weigh samples after different periods of imbibition. This method is not free from errors as the seeds have to be freed from adherent water before weighing, which cannot be done accurately, and, during handling and weighing, loss of water always occurs by evaporation. Furthermore, different lots of seeds have to be used for the various measurements, which is cumbersome and a disadvantage in cases where only small amounts of seeds are available.

Kruyt[1] measured water uptake by enclosing the seeds in a water-filled bottle, through the stoppered mouth of which protruded a capillary tube. By watching the fall of the water column in this capillary, water uptake was measured. In this method the seeds are totally submerged, and no attention is given to volume changes of the seeds due to swelling.

In order to determine germination-rate or metabolic changes in small and quickly germinating seeds, the seeds are usually not submerged, but are placed on wet filter paper. When water uptake has to be correlated with findings obtained by this method, the seeds ought not to be submerged, as this treatment changes their germination behaviour. The potometer described here allows water uptake to be measured in a single lot of seeds imbibing on wet filter paper during a prolonged period of time without weighing.

The edge of a Petri dish is ground and a hole blown in the middle of the bottom. A capillary tube about 65–70 cm. long is sealed to the hole and bent

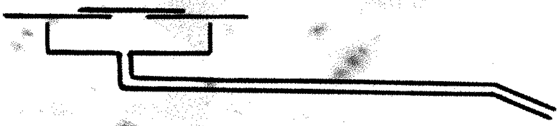

Fig. 1. Diagram of potometer for measuring rate of water uptake in small germinating seeds (not drawn to scale)

as shown in Fig. 1. A ground-glass plate with a small opening in the middle, and a cover-glass or a glass slide to cover up the opening are used to close the potometer.

Before use the capillary is filled completely with water from a pipette through the Petri dish, and the free end of the capillary inserted into a beaker filled with water. A fitting filter paper is quickly inserted into the Petri dish and will absorb water from the capillary. By lifting the free end of the capillary from the beaker, an air-bubble can be introduced into the capillary, which is then lowered again. The potometer is then left open until the bubble has risen to the horizontal part of the capillary. Now the potometer is made air-tight with the cover using any sealing agent and left until the bubble has come to a standstill, indicating that the air inside the Petri dish has been saturated with water vapour. The cover is removed, a measured amount of seeds speedily spread on the filter paper and the cover instantly replaced. When a cover without an opening is used, the air pressure in the Petri dish might be increased by the closing procedure, which will result in a backward move of the air bubble, but when an opening is made in the plate, it can be quickly put in place. The opening has to be immediately closed by sliding the cover-glass smeared with 'Vaseline' sideways over it. Rate of water uptake is determined by reading the movement of the air bubble against a millimetre-scale behind the capillary.

It is advisable to have the potometer in a fixed position in a constant-temperature room and do the handling with the help of forceps and not by hand, in order to avoid temperature changes.

In our laboratory water uptake in photo-sensitive lettuce seeds has been determined by this potometer. The results will be published elsewhere.

A Slide-trap Method for the Isolation of Soil Fungi

THE slide-trap method of isolating actively growing soil fungi, described by C. J. La Touche[1], was used in an investigation of the fungus flora of a podsolized *Calluna*-heathland soil. The method was found to be highly selective of rapidly growing species and indeed, with very few exceptions, only permitted the isolation of *Trichoderma viride* from the surface soils. A modified slide-trap was designed which greatly reduced this selectivity and permitted the isolation of a wide range of species.

The modified slide-trap consisted of a shallow chamber (Fig. 1, *Y*) covered by a glass microscope slide (Fig. 1, *X*). A 'Perspex' strip (3 in. × 1 in. × $\frac{3}{32}$ in.) formed the base of the chamber, narrow lengths ($\frac{1}{8}$ in. × $\frac{3}{32}$ in.) of the same material formed the four walls and the chamber was divided into two unequal parts by a crosspiece. Chloroform was used for joining the 'Perspex' surfaces.

The chamber was stored in alcohol and sterilized by flaming when required. Melted agar was introduced into the larger section of the chamber by means of a sterilized pipette, where it spread evenly to form a thin layer (Fig. 1, *Z*). The chamber was then covered by a sterilized glass slide, which was firmly fixed in position by two wire paper clips when the agar had solidified. All manipulations were carried out under a sterile hood in an inoculating room.

Fig. 1. Modified La Touche slide-trap

Slide-traps were immersed vertically into the soil to such a depth that the larger portion of the chamber was completely buried. The slot-shaped hole to receive the slide-trap was conveniently prepared with a square-ended chisel blade. Traps were buried in groups and were protected from rain by an inverted U-shaped piece of zinc sheeting.

After a suitable period of incubation in the soil, during which fungal hyphæ penetrated between the glass and 'Perspex' surfaces and colonized the agar medium, the slide-traps were returned to the laboratory. In routine isolation work the slide-traps were opened and portions from the edges of the agar medium were removed and plated. Usually nine small sectors of agar were removed, four from the upper part of the isolation chamber (Fig. 1, II, 1–4) and five from the lower part. These two groups of agar strips were plated separately, thus enabling a rough distinction to be made between those mycelia which penetrated the traps from the upper and lower levels of the soil sampled. Generally, two, three or four species were isolated from each slide-trap.

These modified slide-traps were economical of time and materials and were simple to use; the results obtained by their use were in close agreement with those obtained by the immersion tube method[2] and will be discussed in greater detail elsewhere.

Heat Treatment and Tissue Culture as a means of freeing Potatoes from Virus Y

A NUMBER of workers have shown an effect of high temperatures on plant viruses. By heat treatment, potato tubers have been freed from leafroll[1] and witches'-broom[2]; but as yet there has been no reported success with heat treatment as a means of freeing potatoes from virus Y.

The most important potato variety grown in New Zealand, Aucklander Short Top, has been shown to be 100 per cent infected with potato viruses X and Y[3]. Therefore, efforts have been directed towards eliminating virus from selected tubers, which would then become the foundation for improved seed stocks.

Table 1

Treatment	Material	Apices detached	No. surviving	No. free from virus Y
38° C.; 28 days	3 tubers	16	6	0
38° C.; 21 ,,	1 ,,	14	2	0
38° C.; 15 ,,	2 ,,	10	0	0
38° C.; 7 ,,	2 ,,	12	7	4
35° C.; 7 ,,	1 ,,	10	2	1
35° C.; 7 ,,	2 ,,	7	3	0
35° C.; 16 ,,	9 cultures	9	6	5
35° C.; 14 ,,	2 ,,	2	1	1

Tubers were sprouted in darkness and when sprouts were 1–2 cm. long, the tubers were removed to incubators kept at either 35° C. or 38° C. for varying periods (Table 1). After treatment, the terminal 5 mm. of each sprout was detached and surface-sterilized with a 25 per cent solution of commercial sodium hypochlorite with the addition of a small amount of detergent. The shoot tips were recovered in test-tubes on White's media[4] containing 0·7 per cent agar with the addition of pantothenic acid[5]. Cultures were placed in a glasshouse. When sufficient growth had been made, the rooted plantlets were transferred to John Innes compost in pots. They were each tested at least twice for virus content—when 2–3 in. high and when fully grown—by sap inoculation to *Datura stramonium* L. and *Nicotiana tabacum* L. (var. White Burley). If symptoms of virus Y failed to develop on the tobacco plants, they were re-inoculated with a severe strain of virus Y to test for the presence of mild strains.

In another experiment, sprout tips were established in culture under glasshouse conditions and later transferred to the incubator at 35° C. During treatment, these cultures developed some new etiolated growth which was removed and recovered in culture.

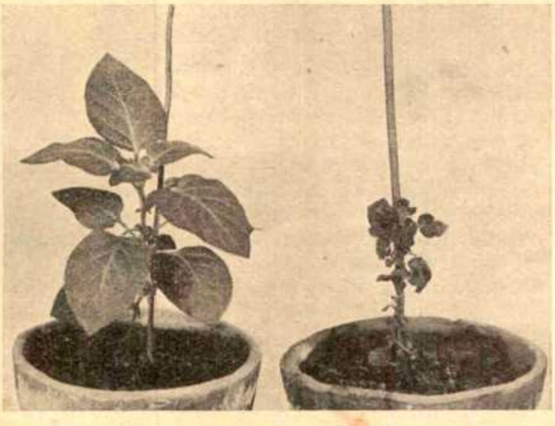

Fig. 1. Left: virus X only; right: viruses X + Y

Although in most cases heat-treated tubers failed to germinate when planted, all those that did proved to be infected with viruses X and Y. However, of eighty apices detached, twenty-seven survived for testing. All showed virus X reaction, but eleven plants failed to give a virus Y reaction.

The plants which were apparently free from virus Y will have to be tested over an extended period before they can be definitely regarded as free. However, under glasshouse conditions, they are much more vigorous than the plants infected with virus X and Y (Fig. 1).

Similar tuber treatments have been carried out on another important variety, Dakota Red, which is wholly infected with virus X. All of thirty-four surviving plants reacted at first test on *D. stramonium*.

This work is being extended.

Diffusion of a New Habit among Greenfinches

Daphne mezereum L. is a compact, pink, pre-vernal shrub, smothered with a profusion of fragrant blossom in March or earlier, and often planted near a living-room window to cheer one up at that season. It has a natural temperate distribution from the Atlantic to the Altai Mountains[1]. *Chloris chloris* L., the greenfinch, has a distribution which, apart from introductions, is somewhat similar[2]. Thus the two species have probably shared a large geographical area for some ten thousand years, apart from earlier Pleistocene migrations. On the borders of calcareous woods there is an overlap between their natural habitats, and they have been together in gardens for several centuries. During the past fifty years no distinctive association between the two species appears to have been reported[2,3].

The fruit of *D. mezereum* is a 10-mm. scarlet drupe, with an internal structure like that of the plum, *Prunus*. It is effectively adapted to alimentary dispersal by such birds as *Turdus merula* L., the blackbird. But in recent years[4] certain greenfinches have obtained a new source of nutrition, at the same time wrecking the life-cycle of *Daphne*. A pair of birds, usually, will visit and strip the bush in May or early June, and while the fruits are still green. They can then crack the immature stones and devour the large seed. Often, no doubt, this considerably assists the feeding of the first brood of nestlings[2,5].

Preliminary reports[4] show that this new behaviour is increasing rapidly in frequency, with 42 per cent of cases occurring only within the last two seasons. I should be very grateful for further information, by postcard, about: (*a*) the location of any *D. mezereum* bush under observation; (*b*) whether or not this despoliation has occurred, and (*c*) the year of first occurrence.

Further information which may help to elucidate the origin and spread of the phenomenon would be welcome. For example: (*d*) For how many years was an observed *Daphne* bush at first free from attack? (*e*) Did the attack have a different pattern in the first year from that of subsequent years? (*f*) How many adult or juvenile birds take part? (*g*) After the first season of despoliation, was the bush ever spared? The opening of milk bottles by tits (*Parus*)[7] was preceded by the introduction of milk bottles; there is no equally clear initiating factor in this instance.

It is hoped that the survey will provide information as to how far *de novo* discoveries by individual birds, on one hand, and cultural diffusion, on the other, have contributed. Besides recent instances, positive and negative, information from earlier years and from outside Britain would be especially appreciated. Appropriate lines of protective action by the horticulturist are discussed elsewhere[6].

Colour Illusions and Aberrations during Stimulation by Flickering Light

The production of illusions of colour by intermittent visual stimulation has been familiar since the description of the 'artificial spectrum top' by Benham[1] in 1895; but with the traditional arrangement of rotating black-and-white chequered disks the subjective sensations are not particularly vivid. Since the introduction of the electronic stroboscope to psychophysiological experiment by Walter, Dovey and Shipton[2] in 1946, thousands of normal and clinical subjects have been subjected to intensive visual stimulation by flickering white light, and all report sensations of pattern, movement and colour. The descriptions vary greatly from subject to subject; in some, the impressions are particularly intense only at certain frequencies. Most subjects have no difficulty in recognizing the illusory character of the colours: Margiad Evans[3] describes them as ". . . pure ultra unearthly colours, mental colours, not deep visual ones. There was no glow in them but only activity and revolution". None the less, the colours are 'real' enough to act as conditioned stimuli, for Brady[4] has shown that subjects who have been conditioned to give a psycho-galvanic skin response to red light will give the 'red' response when stimulated with white light flickering at a particular frequency and at multiples of the critical rate.

The relation of these phenomena to the various theories of colour vision is by no means clear, and a few simple experiments have been made to see whether the illusory colour sensations affect the results of tests for colour blindness administered to normal persons. The hidden-figure colour mosaic cards devised by Ishihara (English edition)[5] were presented successively to a number of subjects and were viewed only by the light of an electronic stroboscope giving blue-white flashes lasting about 20 μsec. and with a peak illumination of about 80,000 ft.-candles. The flash-rate was set at 1 flash per sec. and the subject was asked to comment on the pattern seen, the flash-rate being increased gradually after each comment. In general, the subjects found no difficulty in identifying the figure in the orange-grey contrast cards (Nos. 1 and 32), but were confused and often mistaken when viewing the more complex brown-green and blue-yellow cards. Several subjects with full normal colour vision by steady light gave a number of 'colour-blind' responses during flicker at less than 20 flashes/sec., suggesting various degrees of temporary protanopia or deuteranopia depending on the flicker-rate. The relation between the aberration of colour vision and flicker frequency was not consistent, though most subjects gave particularly erratic reports at frequencies between 5 and 10 flashes/sec. One subject, for example, viewing card 2, saw a 3 (the red-green blind response) at 9 flashes/sec. and an 8 (the normal response) at 12–15 flashes/sec. The same subject gave fifteen other 'colour-blind' or anomalous responses to the thirty-two cards; the commonest effect was a combination of the normal and colour-blind responses to provide an 'original' response; for example, a card containing the figure 5 for normals and 2 for colour-blind was seen as a 3.

In the absence of a rigorous and detailed neurophysiological theory of colour vision, it is difficult to account for this effect; but in view of the dramatic and often paradoxical effects of rhythmic as opposed to steady stimuli[6], it is not surprising that the visual channel should give an equivocal output when supplied with intermittent signals. Careful analysis of the effect should, however, provide a clue to the code relations between the retinal colour analysers and the cerebral receiving zones.

Structure of Collagen

An arrangement of three non-coaxial helical chains linked to one another by hydrogen bonds approximately perpendicular to the length of the chains was suggested as the basis of the structure of collagen two years ago[1]. This structure explained the occurrence of a fraction of more than one-third of glycine residues and could readily accommodate proline and hydroxyproline residues, besides explaining the infra-red dichroism. The exact nature of the helices (namely, three residues per turn) was later found not to be quite correct for collagen, the X-ray pattern of stretched collagen[2] indicating the occurrence of $3\frac{1}{3}$ residues per turn[3]. The presence of such a non-integral number of residues per turn required that the three chains must all be further coiled around. The coiled-coil structure[4] retained the essential features of the earlier one as regards the location of amino-acid residues and the orientation of the NH- and CO-bonds. However, it is interesting to note that the simpler non-coiled-coil structure has been found to be the basis of the arrangement of polypeptide chains in polyproline[5] and in polyglycine II[6]. Thus, it appears that the triple chain structure, with minor modifications, is a configuration which might be found also in other proteins and polypeptides. There is, in fact, good evidence to show that elastin belongs to this type[7].

Recently, two interesting articles have appeared[8,9] which discuss the polypeptide chain configuration in collagen. Rich and Crick[8] have criticized the revised structure proposed from this laboratory[4], on considerations of stereochemistry and amino-acid sequence. Both these difficulties were known to us and were in fact considered in a paper[10] discussing this structure in detail. It was found impossible to avoid short contacts if two good interchain hydrogen bonds were to be formed for every three residues. Consequently, models were built up which were stereochemically more satisfactory. It was then found, as Rich and Crick have found, that only one hydrogen bond can be formed for every three residues in each chain of the triple chain. However, two configurations are possible, both of which are quite satisfactory so far as the backbone of the structure is concerned. The two structures may be called the plus and the minus structures, since they could be obtained from the one described earlier[4] by rotating the minor helices about their own axes through a positive or negative angle (ψ say). These two possibilities are respectively similar to the structure I and structure II of Rich and Crick[8] and the anti-clockwise and clockwise structures of Cowan, McGavin and North[9].

In each case, the best arrangement was determined using the graphical method[10], but retaining the condition of exact coiled-coiling. If the major helix radius is denoted by R, the best values were found to be:

For the plus structure: $R = 2{\cdot}85$ A., $\psi = +40°$.
For the minus structure: $R = 2{\cdot}78$ A., $\psi = -15°$.

Of the two, the minus structure was preferred, as its properties were similar to those of the earlier structure[4,10] except that there were no short contacts of any type. The hydrogen bond length is 2·76 A. and the angle between NH and N....O is about 15°. Every third residue in each chain must be of the G-type, but the other two residues R_2 and R_3 in the sequence —G—R_2—R_3— can accommodate a pyrrolidine ring without strain. Thus, the sequence gly-pro-hypro can readily occur in this structure. The position R_3 is assigned to hydroxyproline, the hydroxyl group of which links through a hydrogen bond to a carbonyl oxygen in another triple-chain rod. The distance between these rods could be equal to 12 A., the value found for dry collagen, unlike the value 11·5 A. required earlier.

Both Rich and Crick[8], and Cowan *et al.*[9], have favoured the other possibility, namely, the configuration analogous to our plus structure. However, the minus structure appears to be more probable for the following reasons.

(*a*) The Fourier transform of the minus structure agrees better with experiment than the other one. (The optical transform was obtained by Drs. Rich and Crick and by Drs. Cowan and McGavin, and I am very grateful to them for this.)

(*b*) If an exact coiled-coiling is assumed and hydroxyproline residues occur in position R_3, then the distance between some of the carbon atoms in the pyrrolidine ring and the carbonyl oxygen of a neighbouring chain are found to be too short in the plus structure. Rich and Crick (personal communication) have overcome this by not insisting on an exact coiled-coiling and also by making one of the chains slightly different from the other two. Although the effect of these may not show up in the X-ray pattern, such a modification should obviously be attempted only if other approaches fail.

(*c*) In the plus structure, the G-type α-carbon atom can readily accommodate a methyl group in its side-chain with a slight strain, so that an alanine residue could occur in this position. On the other hand, it would appear that every third residue in collagen must be a glycine residue, because such residues are never found to be less than one-third in number and since no sequence of three residues has been found which does not contain a glycine residue[11,12] (with one solitary exception).

(*d*) Studies carried out in this laboratory on the effect of tanning at different *p*H's and of certain salt solutions on the wide-angle pattern of collagen indicate that the hydroxyproline cross-linkages are external to the triple chain.

There seems to be no reason why the structure should be based on an exact coiled-coil, as was assumed in our studies. The X-ray pattern only demands that every third residue must occur on a simple helix of pitch 85·8 A., with thirty residues per turn, in each of the three chains. If only this condition is put in, then almost straight hydrogen bonds can be formed in the minus structure, and yet having no short van der Waals contacts. Although there are thus various points in favour of the minus structure, a second set of hydrogen bonds cannot be formed and a number of imino-hydrogens are systematically not hydrogen-bonded. This is not really satisfactory. It is possible, however, for these hydrogens to be bonded to a carbonyl oxygen in another chain of the same triple chain through a water molecule. It is probable that water exists in such a firmly bound form in collagen (McGavin, S., personal communication), but a careful study is required of this question.

The work reported here has been done in collaboration with Messrs. Y. T. Thattachari, V. Sasisekharan and M. S. Santhanam, and I wish to acknowledge their valuable assistance. Fuller reports will be published elsewhere.

Diffraction from Dislocations

Wilson[1] has calculated the nature of the diffraction from a cylindrical crystal with a single axial screw dislocation. Diffraction from an edge dislocation is more difficult to treat theoretically, because of the more complex nature of the elastic field surrounding the dislocation. An approximate treatment has been given by Wilson[2], who assumed that the displacements of the atoms were parallel to the Burgers vector. We have succeeded in solving the diffraction problem for a cylindrical crystal with an axial edge dislocation, in which the displacements correspond to isotropic elastic theory. Two independent methods were used: straightforward calculation (by T. S.), and direct observation in a Lipson diffractometer of the optical diffraction pattern of a two-dimensional grating representing the crystal (B. T. M. W.). In Fig. 1 we reproduce the optical diffraction pattern given by a grating representing (*a*) a perfect crystal (no dislocation) and (*b*) a simple-cubic crystal with an edge dislocation normal to the plane corresponding to the plane of the grating.

Our results can be summarized as follows. The h-axis in reciprocal space is parallel to the slip direction (Burgers vector) and the l-axis to the axis of the dislocation. (1) Any spreading of the diffracted intensity in reciprocal space is confined to the planes $l = 0, \pm 1 \ldots$, and the intensity within these planes is independent of l. (2) The $h0l$ reflexion is broader and weaker than the $0kl$ reflexion for equal values of h and k. (3) The maxima of the $h0l$ reflexion are displaced from the ideal reciprocal lattice point by an amount that increases linearly with h; the maxima of the $0kl$ reflexion are also displaced, but the displacement is roughly independent of k for small k. (4) The intensity at the ideal $h0l$ and $0kl$ lattice points is zero for $h,k > 4$. (5) The form of the distribution of intensity around an ideal reciprocal lattice point depends on its co-ordinates in reciprocal space, on the strength of the dislocation and on the value of Poisson's ratio, but not otherwise on the crystal structure. In contrast with the case of a screw dislocation[1], the spread of intensity around the ideal reciprocal lattice point is not of circular symmetry.

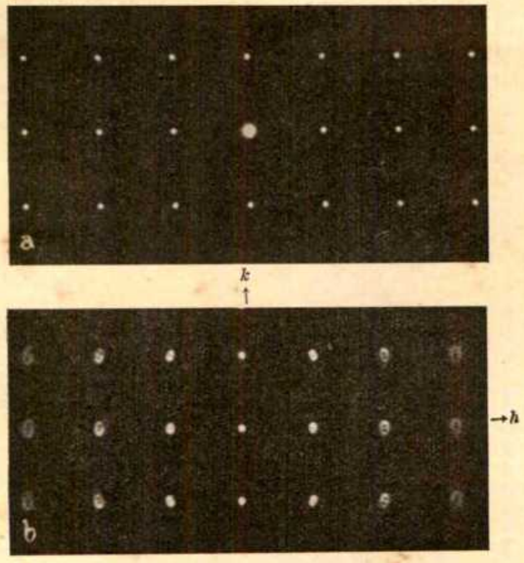

Fig. 1. Diffraction patterns from gratings representing (*a*) perfect crystal, (*b*) crystal with dislocation. The horizontal axis in (*b*) corresponds with the slip direction

These results were obtained using an average value of 0·3 for Poisson's ratio. It is clear that the diffraction pattern is quite different from that proposed by Wilson on the basis of the more approximate theory[2].

Our thanks are due to Prof. F. C. Frank for discussion of this problem, and to Dr. J. Thewlis, who suggested the use of the optical method for its solution.

Galvanic Measurement of Dissolved Oxygen

An exceedingly sensitive static[1] as well as continuous[2] method for determining molecular oxygen in the gas phase has been described by Hersch. This discovery has led to the development of a reliable commercial instrument for the continuous indication and recording of oxygen in gases. Hersch has also proposed[2] the application of this method to oxygen dissolved in boiler water, effluents, biofluids, and fermentation media by driving the oxygen into an inert carrier.

The measurement of oxygen in an aqueous phase by polarographic or amperometric means has been often described, but the sensitivity of these methods is limited by the value of the oxygen diffusion current. Moreover, reducible constituents other than oxygen can interfere, while salt deposits and adsorbable organic material progressively block the cathode[3]. The application of the Hersch galvanic system to liquids in the way suggested would largely eliminate these drawbacks.

We have experimented with a simple apparatus designed to adapt the method described by Hersch to the measurement of dissolved oxygen, which has proved effective and reliable.

We used demineralized water 'scrubbed' by means of hydrogen passed via a 'Deoxo' purifier through a sintered glass disk at the bottom of a reservoir. The water is fed, at constant flow-rate determined by a static head, to a glass vessel having an outlet at the bottom into a vertical tube via a constriction constructed in such a way that a vortex is formed. The vessel contains oxygen-free hydrogen which is sucked into the vortex and flows in a series of bubbles with the water down the vertical tube, taking from the water a proportion of the dissolved oxygen. We have found it surprisingly easy to establish conditions in which the proportion of oxygen transferred to the hydrogen in this 'oxygen exchange column' remains constant. At the bottom of the column, the water/hydrogen mixture runs into a vessel of larger diameter where the water separates from the gas and flows out through a constant-head device, while the gas flows upwards over a Hersch dry cell which measures its oxygen content. The hydrogen then passes via a small 'Deoxo' purifier to remove the residual oxygen, back to the water inlet vessel.

Calibration has been done (*a*) by bleeding in a measured quantity of air-saturated water and (*b*) electrolytically by passing a known d.c. current between a pair of platinum electrodes immersed in the inlet pipe. Excellent agreement was achieved. Using a flow-rate of 10 litres an hour, and an oxygen exchange column 6 in. long, the cell gave an electrical output of up to 5 μamp. for 1 vol. of gaseous oxygen dissolved in 10^6 vol. of water, that is, 5 μamp. per vol. per million (v.p.m.) ($1 \cdot 4 \times 10^{-9}$ gm./gm.), and the electrical output was linear up to at least 20 v.p.m. (28×10^{-9} gm./gm.).

If the 'Deoxo' purifier be omitted from the hydrogen return circuit, the oxygen content of the circulating gas builds up to a figure which approaches static equilibrium with the water, and the electrical output from the cell is thereby increased several times to between 15 and 20 μamp. per v.p.m., but the time taken to reach equilibrium is increased. Incidentally, we have shown the effectiveness of scrubbing with 'Deoxo' purified hydrogen. We could, without difficulty, reduce the oxygen content of our water supply to less than ½ v.p.m., as indicated by the Hersch cell.

The method appears to have many advantages over those previously described. (*a*) Its response is rapid (5–10 sec.); (*b*) it gives a continuous indication and/or record; (*c*) it requires no addition to the water other than oxygen for calibration, and this can readily be done electrolytically; (*d*) it is unaffected by the presence of dissolved salts in the liquid.

We are investigating the effect of dissolved gases other than oxygen; for example, carbon dioxide, sulphur dioxide and ammonia, but it is believed that none of them will present an insurmountable problem.

A New Alumina Trihydrate

During the development of a platinum-alumina catalyst, X-ray studies have revealed that, in addition to the well-known gibbsite and bayerite, a third crystalline form of $Al(OH)_3$ exists. Pure samples of this new trihydrate have not been obtained. It is generally accompanied by bayerite, often by both bayerite and gibbsite In samples where this new crystalline trihydrate is the major component, it has been possible to determine its chemical composition as $Al(OH)_3$ and to resolve its X-ray diffraction pattern. This pattern of the new phase (as recorded with a Geiger counter spectrometer using copper *Kα* radiation) is:

Spacing	Intensity	Spacing	Intensity
4·785 A.	100	3·18 A.	11
4·33	20*	2·39	15
4·20	15	2·26	15
4·15	13	2·01	11
3·89	7	1·898	11
3·60	7		

* Intensity uncertain—overlap with bayerite

Preparations in which this new phase is encountered start with either aluminium chloride or nitrate solution. Ammonium hydroxide is added to precipitate an alumina hydrogel. This gel is washed with ammoniacal water, then adjusted to *p*H 7·5–9 with ammonium hydroxide, in which condition the gel is gradually converted to crystalline trihydrate. Nitrogen, chloride and other impurities in the dried product are all less than 0·1 per cent. It frequently contains all three trihydrates, the relative proportions depending upon *p*H, ionic concentration, seeding and temperature. Crystallite sizes are of the order of 1000 A.

The strongest diffraction line of each of the three phases is in the vicinity of 4·8 A. (18–19° with copper *Kα* radiation). The integrated intensities of these three lines appear identical for 100 per cent of the phase (when preferred orientation effects are overcome). The spacing 4·785 A. for the new phase is midway between that for gibbsite, 4·843 A., and that for bayerite, 4·720 A. These patterns for three samples are shown in Fig. 1.

The gibbsite structure, as described originally by H. Megaw[1], is a layer lattice, the packing of layers being such that hydroxyl groups in one layer are directly above the neighbouring hydroxyls in the next layer. Bayerite, as described by A. Unmack[2], has the same layers as gibbsite, but the packing resembles that of brucite with the hydroxyl groups from contiguous layers in a close-packed array. The 4·843 A. gibbsite

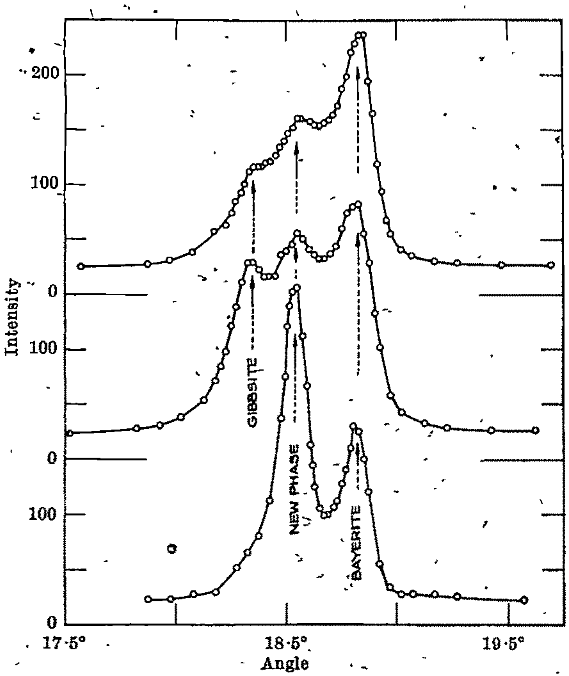

Fig. 1. X-ray diffraction patterns of samples consisting of mixtures of the three alumina trihydrates

and the 4·720 bayerite lines are basal reflexions. The same may be assumed for the 4·785 A. line from the new phase, in view of its proximity and identical intensity. It would appear that the new phase with a 'layer spacing' equal to the average of the gibbsite and bayerite spacings may be a structure wherein the two types of packing alternate. This should lead to a weak X-ray reflexion corresponding to a two-layer periodicity for the new phase. No such reflexion has been observed. If present, its intensity is less than a thousandth of that of the 4·785 A. line.

The requirements cited by F. C. Frank[3] and V. Vand[4] for polymorphism arising from screw dislocations are fulfilled, namely, two closely related types of packing, the gibbsite and the bayerite types. There seems to be a good chance that the new phase is a screw dislocation polymorph, similar to the silicon carbide polymorphs. In the new phase the Burgers vector or height of the spiral growth step may be considered as two layers. The interface between these two layers would probably be a gibbsite-type interface. The interface between the stationary surface and the growing surface would be of bayerite type. Bayerite itself might then be looked upon as a screw dislocation growth form in which the Burgers vector was one layer—the constraint imposed during this type of growth may prevent the gibbsite-type packing, permitting instead a simple close-packing of the brucite type. Growth habits of these three phases seem to support this hypothesis. Electron microscopy and preferred orientation effects in X-ray diffraction indicate that gibbsite usually grows as platelets parallel to the layers of its layer lattice. Bayerite appears as rods or tapered rods the long direction of which appears roughly perpendicular to the layers of the layer lattice. The new phase appears intermediate, showing neither preferred orientation nor preferred growth directions.

The dehydration of all three trihydrates occurs at about 200° C., gibbsite yielding χ-alumina and boehmite; bayerite and the new phase yielding η-alumina. These distinctions are based upon the nomenclature of H. C. Stumpf *et al.*[5].

Throughout our catalyst development programme the name 'randomite' was attached to this phase, as at first it was thought to be a random stacking structure. In view of the complete X-ray pattern now available, it is clear that this nomenclature is inappropriate. We suggest that it be called bayerite-II, the original bayerite to be distinguished where necessary by Roman numeral as bayerite-I. Several reasons exist for suggesting a name showing its relationship to bayerite, including structure and growth features, conditions favouring formation, and dehydration products.

Self-inflation in a Gobioid Fish

THE ability to inflate the body-cavity by pumping in air or water through the mouth is found in several groups of fishes, chiefly highly specialized and otherwise rather degenerate types such as the well-known puffers, in certain forms from deeper waters and in some small sharks.

Mr. W. O. Mylo, of South-West Africa, recently sent me a small fish which was caught in a tide pool near Swakopmund, and which after capture blew itself up in the same fashion as a Tetraodon. On examination, this fish proved to be *Gobius bibarbatus* von Bonde, 1923. Although rather desiccated, it was plain that the abdomen had been considerably distended. On soaking, the fish became pliable and it was possible to estimate the degree of inflation that had been attained. In its distended condition the skin of the abdominal region bore scales, but each completely isolated in its own pocket. In the uninflated fish the abdomen is completely covered by normally imbricating scales. On distension these must slide apart leaving bare patches of translucent skin between. A skin structure of this type is unusual and would merit closer study in fresh material.

This is apparently the first case of a self-inflating mechanism to be reported in fishes of this type. Although generally placed in the broad genus *Gobius* Artedi, 1792, *bibarbatus* is distinguished from all other South African gobies by having what have generally been described as two 'barbels' beneath the chin. Examination reveals that these are not true barbels, but the briefly prolonged lateral apices of a low transverse mental skinny flap. This structure and the power of self-inflation clearly merit generic distinction for this fish, and *Sufflogobius* new genus is now proposed for it, genotype *bibarbatus* von Bonde.

FORTHCOMING EVENTS

Monday, April 16

British Society for the History of Science, Philosophy of Science Group (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 5.30 p.m —Mr. G. Spencer Brown: "Paradoxes of Probability".

Society of Chemical Industry, Pesticides Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m. —Annual General Meeting. Dr. R. A. E. Galley: "Pesticides in Retrospect and Prospect".

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Dr. H. G. Taylor: First of Three Cantor Lectures on "Modern Welding". (Further Lectures on April 23 and 30.)

Tuesday, April 17

Institution of Electrical Engineers, Measurement and Control Section (at Savoy Place, London, W.C 2), at 5.30 p.m.—Mr. F. C. Widdis: "The Indirectly Heated Thermistor as a Precise A C./D.C. Transfer Device"; Mr. A. M. Thompson: "A Bridge for the Measurement of Permittivity".

Scientific Film Association (joint meeting with the Federation of Film Societies and l'Institut Francais, at Institut Français, Queensbury Place, South Kensington, London, S.W.7), at 6.30 p.m.—"Films in the Popularization of Science".

Royal Aeronautical Society (at 4 Hamilton Place, London, W.1), at 7 p.m.—Mr. E. L. Ripley: "Investigation of Aircraft Accidents".

Tuesday, April 17—Saturday, April 21

Institute of Metal Finishing (at the Norbreck Hydro, Blackpool)—Annual Conference.

Wednesday, April 18

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m —Dr. Cyril Bibby: "T. H. Huxley and Technical Education".

Institute of Navigation (at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 5 p m.—Meeting on "Relative Movement and the Collision Problem".

Royal Meteorological Society (at 49 Cromwell Road, London, S W.7), at 5 p.m.—Annual General Meeting. Dr. R. C. Sutcliffe: "The Moisture Balance of the Atmosphere" (Presidential Address).

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Mr. B. P. Emmett: "The Television Audience in the United Kingdom".

Institute of Fuel (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 5 30 p.m.—Annual Corporate Meeting.

Royal Microscopical Society (at Tavistock House South, Tavistock Square, London, W.C.1), at 5.30 p.m.—Dr. R. J. Goldacre: "Simple Micromanipulators".

Society of Chemical Industry, Corrosion Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m. —Annual General Meeting. Dr. U. R. Evans, F.R.S.: "Pitting and Cracking" (Spring Lecture).

Royal Aeronautical Society, Graduates' and Students' Section (at 4 Hamilton Place, London, W.1), at 7.30 p m.—Mr. R. M. Fitzgerald: "Gas Turbines—Propeller or Jet?"

Thursday, April 19

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Meeting on "Biological Work at the Forest Products Research Laboratory, Princes Risborough".

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p m.—Prof. H. W. Melville, F.R S.: "Addition Polymerization" (Bakerian Lecture)

Institution of Mining and Metallurgy (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. F. D. Richardson and Mr. J. C. Billington: "Copper and Silver in Silicate Slags"; Mr. A. Alec Jones: "Underground Mining in the Frodingham Ironstone".

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. W. Ledermann: "The Multiplicator of a Group".

Royal Aeronautical Society (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6 p m.—Lt.-Col. Charles E. Yeager, U S.A.F.: "High Speed Experimental Test Flying".

Society of Chemical Industry, Road and Building Materials Group (in the Lecture Hall, Junior Institution of Engineers, Pepys House, 14 Rochester Row, London, S.W.1), at 6 p.m.—Annual General Meeting. Dr. A. R. Lee and Mr. H. G. Barnes: "Dense Tar Surfacing".

British Institute of Radiology, incorporated with the Röntgen Society (in the Reid-Knox Hall, 32 Welbeck Street, London, W.1), at 8 p m.—Ordinary Meeting, followed by Prof. George de Hevesy. "Application of Radioactive Tracers in Radiobiology" (Thirty-fifth Silvanus Thompson Memorial Lecture).

Thursday, April 19—Friday, April 20

Institution of Chemical Engineers, Graduates and Students Section (at Nutford House, Brown Street, London, W.1)—Symposium on "Recent Developments in Effluent Disposal".

Friday, April 20

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4 15 p.m.—Geophysical Discussion—"Improvements in Seismic Prospecting". Chairman: Mr. B. C. Browne. Speakers: Prof. Russell Rait and Dr. S. Wyrobek.

Institution of Mechanical Engineers, Education Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 5.30 p.m.—Mr. D. L Marples, Mr J. F. A. Radford and Mr. J. L. Reddaway: "An Approach to the Techniques of Graduate Training".

Institution of Electrical Engineers, Education Discussion Circle (at Savoy Place, London, W.C.2), at 6 p.m.—Discussion on "Theories of Electromagnetic Induction". Opening Speaker: Prof. G. W. Carter.

Austrian Institute (at 28 Rutland Gate, London, S.W.7), at 6.30 p.m.—Prof. E. Schmid (University of Vienna): "The Influence of Structural Ordering on the Properties of Metallic Materials".

Society of Chemical Industry, Fine Chemicals Group (in the William Beveridge Hall, Senate House, University of London, W.C.1), at 7 p.m —Debate on a motion "That Science Can Provide as Good an Education as the Humanities". Speakers: Dr. R. P. Linstead, F.R S., Prof. A. R. Ubbelohde, F R.S., Mr B. L. Hallward and Mr. H. D. P. Lee. Chairman: Sir William Ogg.

Saturday, April 21

British Interplanetary Society (in the York Hall, Caxton Hall, Caxton Street, London, S.W 1), at 6 p m.—Annual General Meeting.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Statisticians (with a degree in statistics, or in mathematics with appropriate qualifications in statistics, and preferably with some experience in the application of statistical techniques (including punched cards) to practical problems) in the Statistics Branch of the National Coal Board in London—The National Coal Board, Hobart House, London, S.W.1, quoting SS/247 (April 27).

Research Assistant in Biochemistry at the University College of the West Indies, for duties which include research on malnutrition problems and possibly some teaching and chemical pathological work for the University College Hospital—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (April 27).

Lecturer in Pure Mathematics—The Registrar, King's College, Newcastle-upon-Tyne (April 28).

Assistant in Mathematics—The Secretary of University Court, The University, Glasgow (April 30).

Assistant in the Department of Geography in St. Salvator's College—Joint Clerk to the University Court, College Gate, St. Andrews (April 30).

Assistant Lecturer or Lecturer in Zoology—The Secretary and Registrar, University College of North Wales, Bangor (April 30).

Herdman Postgraduate Student in Marine Zoology, to undertake research work at the Marine Biological Station, Port Erin, Isle of Man—The Registrar, The University, Liverpool (April 30).

Lecturer (Grade II) in the Department of Botany—The Registrar, The University, Bristol (April 30).

Pig Husbandry Research Officer (graduate in science or agriculture, with postgraduate experience), for duties which will include experimental work, management of the pig unit, and some teaching—The Registrar, Wye College, near Ashford, Kent (April 30).

Research Fellow in Mathematics—The Secretary of University Court, The University, Glasgow (April 30).

Bleacher's Association Ltd. Fellow (with a leaning towards physical or physical-organic chemistry) in the Department of Textile Industries, for research on cellulosic fibres—The Registrar, The University, Leeds 2 (May 1).

Reader in Roman-British History and Archæology tenable in the Newcastle Division of the University—The Registrar, University Office, 46 North Bailey, Durham (May 5).

Assistant Lecturer in Chemistry and an Assistant Lecturer in Geography—The Secretary, Birkbeck College, Malet Street, London, W.C.1 (May 7)

Lecturer in Applied Mathematics—The Secretary and Registrar, The University, Southampton (May 7).

Microbiologist (with a first- or second-class honours degree, and preferably with postgraduate research experience in bacteriology or allied fields) for basic research at Aberdeen on the taxonomy and biochemistry of marine bacteria—The Superintendent, Torry Research Station, Aberdeen (May 8).

Lecturers in Botany, Zoology, Chemistry, Physics and Mathematics at the University College of Rhodesia and Nyasaland—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (May 10)

Lecturer in Engineering—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (May 12).

Lecturer (with special qualifications in economic geography) in Geography—The Secretary, Queen's University, Belfast (May 15).

Chair of Mathematics at the University College of Rhodesia and Nyasaland—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (May 18).

LECTURER IN EDUCATION at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, May 18).

LECTURER IN AGRICULTURE (Animal Husbandry) at the University College of Rhodesia and Nyasaland—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (May 21).

LECTURER (preferably able to teach mycology) IN BOTANY at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, May 21).

COATS FELLOW (graduate in science of at least one year's standing of a British university) IN CHEMISTRY or PHYSICS, to undertake research in chemistry or physics (excluding nuclear physics)—The Clerk of Senate, The University, Glasgow, W.2 (May 31).

LECTURER IN VERTEBRATE ZOOLOGY at Victoria University College, Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, May 31).

LECTURER or ASSISTANT LECTURER IN EDUCATION at Makerere College (The University College of East Africa)—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1.

LEVERHULME STUDENT for research in CHEMICAL ENGINEERING—The Registrar, Imperial College, London, S.W.7 (July 1).

RADIATION LTD. RESEARCH FELLOW in gaseous fuels and combustion—The Registrar, Imperial College, London, S.W.7 (July 13).

ENGINEER or PHYSICIST (with a first- or second-class honours degree or equivalent in physics or engineering and preferably with a knowledge of modern computing methods) at the Ministry of Supply London Headquarters, to co-ordinate development work on high precision electromechanical and electronic control instruments and systems for guided weapons undertaken by government establishments and industry—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.113/6A.

ANDROGENS

Biochemistry, Physiology, and Clinical Significance

by RALPH I. DORFMAN, PH.D., AND REGINALD A. SHIPLEY, M.D.

(Respectively: Research Professor, Boston University School of Medicine, and Associate Professor of Medicine, Western Reserve University School of Medicine.)

Size: 9¼ *in.* × 6 *in.* 590 *pages* *Illustrated* 108*s. net*

This is possibly the first work devoted specifically to the broad subject of androgens. Drawing on all the information published in this field over the past 30 years, it discusses the male hormones from both the theoretical and applied points of view. A particularly valuable section of the book is that devoted to the clinical aspects of androgens.

SOIL PHYSICS

by L. D. BAVER

(Director, Experiment Station, Hawaiian Sugar Planters Association)

Third Edition

Size: 9¼ *in.* × 6 *in.* 489 *pages* *Illustrated* 62*s. net*

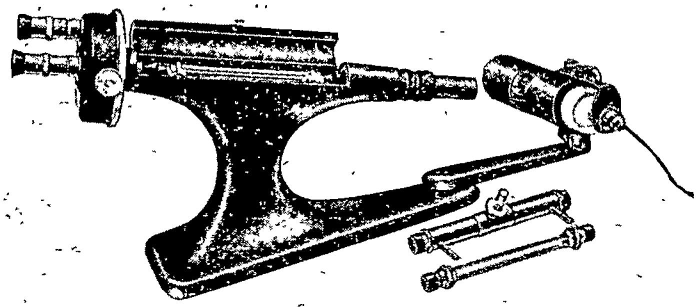
The author has incorporated in this new edition the many major contributions which have added to our knowledge of the subject in recent years. The work has been revised and expanded to provide an even clearer understanding of the basic principles of soil structure.

37 ESSEX STREET, LONDON, W.C.2

PRECISION INSTRUMENTS

Polarimeter Model D

for the estimation of sugar in solutions



Angular, or both angular and sugar, scales can b provided. For use with tubes up to 220 mm. i length and the electric sodium lamp.

Fitted with glass circle and a divided drum, whic replaces the usual vernier.

Now mounted on an inclined base for great comfort in observation. Front focusing of the fie can be supplied with either model. This syste gives a clearly defined field regardless of solutio turbidity and no refocusing is required aft placing the solution tube in the trough.

COPYRIGHT AND SCIENTIFIC DEVELOPMENT

QUESTIONS of copyright were raised at the Royal Society Scientific Conference held in 1948, and in consequence the Council of the Royal Society issued in the following year a Declaration of Fair Copying, to which in the course of a few months more than seventy other societies and publishers in Great Britain had subscribed. The Copyright Bill*, which was read for the first time in the House of Lords on October 26 and after a lengthy examination in committee and on report received its third reading on March 22, is thus of special interest to the scientist and technologist. The Bill illustrates the complications which may arise out of the impact of technological advance and block attempts to adjust the law to the new conditions created. As the Lord Chancellor, Lord Kilmuir, explained in moving the second reading of the Bill on November 15, 1955, it is a comprehensive measure which, when enacted, will contain all the law of Britain on copyright matters. It will replace the Act of 1911, in which the British law of copyright was first codified, and three minor measures which were left unrepealed at that time; but it leaves unrepealed those sections of that Act (15 and 34) which relate to the receipt by certain libraries of free copies of books published in the United Kingdom. Those provisions are not matters of copyright and, as the Lord Chancellor said, are best dealt with otherwise than in a copyright statute.

The present Bill is designed to give effect to the report of the Copyright Committee, of which Lord Reading and Sir Henry Gregory were successively chairmen, issued in October 1952. In accordance with that report, the rights of an author, dramatist, composer or artist in his work are dealt with in one part of the Bill, while those rights given to other forms of copyright, such as sound recordings, broadcasting programmes and the like, are dealt with separately in Part II. So far as possible, the Bill also deals with the rights given to different kinds of works and the acts which constitute infringement in different sections; thus artistic works, for example, are dealt with in a different section from literary, dramatic and musical works—a procedure which, while promoting clarity, also makes the Bill longer and in itself extended the proceedings in the House of Commons.

Apart from restating the law of copyright in a different form, the Bill makes considerable changes in the present law. These, in the main, fall into two categories. First are those which will enable Britain to ratify two international conventions for the protection of copyright. In particular, by omitting the qualifications in the 1911 Act that during the past twenty-five years of the copyright life of a published work that work can be re-published as of right by any person who pays to the copyright owner the statutory royalty of 10 per cent, and the power of the Judicial Committee of the Privy Council at any time after the death of the author of a work which is being published or performed in public to over-ride any refusal of the copyright owner to permit re-publication, it will enable Britain to adhere to the revised convention of the Berne Copyright Union. The Copyright Committee in its report urged that the advantages of continued adherence to the Berne Union were overwhelming and greatly outweighed any disadvantages attending the repeal of these provisions. In particular, as was noted by Lord Conesford as well as the Lord Chancellor, the United States, which has hitherto abstained, has now signed and ratified the Universal Copyright Convention, and this came into force on September 16, 1955. Ratification of the Convention will therefore offer great advantage to British authors and publishers and to British export trade in books.

The second group of changes arises from the scientific advances which have been made in the fields of photo-copying, recording and broadcasting. It is here that the major difficulties arise, and the division of opinion which was manifested in the discussions in Parliament on the Bill was not entirely reconciled. Lord Kilmuir dealt first with the changes that have been required by the improvements in photo-copying, for example, microfilming. These provisions relating to the copying and publication of copyright works in libraries and archives are set forth in clause 7. Such methods have been of great advantage to students, but have placed libraries in jeopardy of actions for infringement. Lord Kilmuir said with justice that it would be helpful if statutory authority were given to libraries to provide methods for copying and also to deal with unpublished manuscripts, of which the ownership of the copyright might be unknown. He claimed that the clause was designed to help the student who needed photocopies for his own use, with the minimum of disturbance to the rights of the copyright owner, and that it also facilitated publication of ancient unpublished manuscripts in public archives where the copyright owner could not be traced.

The clause provides that the copyright in an article contained in a periodical publication is not infringed by making or supplying a copy of the article, if the copy is supplied by a library of a class prescribed by the Board of Trade by regulations made under the clause. The regulations apply solely to libraries not established or conducted for profit, and copies may only be supplied to persons who satisfy the librarian that they are required solely for private study or research, that not more than one copy of the same article is supplied to any one person, nor more than one article in any one publication is copied, and that the costs of production, including a contribution to the general expenses of the library, are met by the persons to whom the copies are supplied.

This clause thus gives force of law, by and large, to the Royal Society's fair copying declaration, but only so far as periodical literature is concerned.

---

* Copyright Bill (H.L.) (As amended on Report.) Pp. 78. (London: H.M. Stationery Office, 1956.) 2s. 6d. net.

Copying from books is dealt with in separate subsections which cover the librarian of such non-profit libraries if he is unable by reasonable inquiry to identify the owner of the copyright in the book it is proposed to copy. It may be doubted, however, whether the Bill distinguishes any more clearly than the report the essential character of the scientist's need for copying. The Lord Chancellor, in moving the second reading in the House of Lords, spoke of the requirement to help those who contribute to the advance of the spiritual side of man, and at the report stage in particular Lord Mancroft, the Joint Parliamentary Under-Secretary of State for the Home Department, was most emphatic as to the need to respect the point of view of the author. Lord Mancroft, however, while alive to the importance of safeguarding the rights of students and of the libraries, was inclined to regard the rights and needs of the author of scientific and technical papers or books entirely in commercial terms, and his opposition to some of the amendments suggested by Lord Chorley was in consequence somewhat over-stated.

As Mr. Leslie Wilson pointed out, in commenting on the Copyright Committee's report (see *Nature*, 170, 1108; 1952), for the scientist, and often for the technologist also, publication is seldom a matter of commercial reward. The financial return, if any, is usually nominal, and the real profit is in the increase of his professional reputation. His interest runs very largely with that of science or technology itself in demanding as wide and free a circulation of his results as possible, and the real problem is that of securing for him and for the community the maximum advantage which inventions like microfilming offer in the way of scientific and technical communication, consistent with fair dealing to those who in the first instance took the responsibility and financial onus of publication. The element of cost has to be considered, but rather in relation to that of publication than in terms of the return to the scientist or technologist.

The question of fair copying requires consideration, in fact, in relation to the problem of scientific communication in general, and to those investigations which have recently been initiated by the Nuffield Foundation. As has already been emphasized, the rights and needs of the scientist or technologist who has written the book or article are closely related to those of the scientific or technical community of which he is a member. Indeed, it could be argued that without the facilities which Lord Chorley stressed, it would be difficult for the scientist or technologist to complete his paper or book, and there is more in the point that Lord Chorley made about the scientist and technologist having the maximum access to the materials he needs than Lord Mancroft was disposed to concede. In these days when costs of publications are mounting out of all proportion to the resources of most libraries, it can easily happen that only an industrial library can afford to subscribe to and file some particular periodical, or in a particular area purchase a very expensive monograph. Unless that library is legally entitled to provide a copy of a particular paper or passage, the scientist or the technologist may be put to an expensive and tedious journey to a distant part of the country, or be unable to consult the reference he needs.

Lord Mancroft rightly emphasized that, although industrial organizations often place their libraries freely at the disposal of scholars, access to them remains a matter of grace and favour. That must remain: they can never be on all fours with the libraries of public institutions and universities or public libraries; but the development of an adequate regional library system in which industrial libraries often already co-operate might well provide a way out of the difficulty. Lord Chorley's attempt to extend the clause to cover such libraries was defeated; but, as Lord Douglas of Barloch pointed out, Lord Mancroft did not really dispose of the argument or appreciate the place which the specialized libraries of industry have now come to occupy in the library resources of Britain.

A second point which occasioned some argument and difference of opinion in the House of Lords relates to the copyright of an article in a periodical. Under clause 4 of the Bill, as Lord Lucas pointed out at the second reading, if the article is commissioned, the copyright rests not in the author, as at present, but in the person who commissions the article. This clause was amended in committee to provide that the work should not be used for a different purpose or published otherwise except by express agreement between the author and the person commissioning the work. The amended clause, however, was challenged on the report stage by Lord Douglas as well as by Lord Chorley and Lord Faringdon, and their objections were not entirely removed by the assurances of the Lord Chancellor and Lord Mancroft.

What seems clear is that some far more fundamental thinking is needed about the impact of modern developments in photo-copying, for example, a scientific or technical communication, than is apparent in the drafting of this Bill. More is involved than questions of copyright and author's rights in fair copying, and it is unlikely that all difficulties will be removed by improvements in the law of copyright. It might have been expected, however, that the Government would be more aware of the practical needs and of the importance of such problems for technological and scientific advance. As it is, the Government appears to be as averse to facing the real issues in regard to the needs of the scientist or technologist as it has been in asserting the public interest against the restrictive practices of the Musicians Union, although the Bill as amended in the report stage deals more realistically with television and sound broadcasts.

Some concern was also expressed, both in committee and at the report stage, as to the effect of the Bill on the use of broadcasting and television in education. In the report stage on February 21, the Lord Chancellor moved the insertion of a new clause after clause 36 covering the use of copyright material for education, which he claimed represented a reasonable balance between the needs of schools and the rights of authors and composers. Quoting from Lord Jowitt's speech on December 1, he agreed that authors and composers have given us much that makes life worth living, and that we should be most careful not to erode their rights more than is necessary. As regards the performance of copyright works and copyright material, the Lord Chancellor said that it is necessary to limit the exception to schools; and although the amendment, as Lord Bridgman admitted, goes a long way to meet the points raised by the local education authorities, Lord Chorley and Lord Silkin expressed disappointment that university and adult education were not also included. Lord Chorley, however, had not sufficiently completed his inquiries to be satisfied that the point was of such importance in university teaching to put down a formal amendment, but there may well be some scope for further inquiry along the lines that have already been pursued at Bristol.

The complexity of the whole subject is indicated by the mere fact that in the nine days the Bill was before the House of Lords nearly three hundred and fifty amendments were considered and some thirty of these were down for the third reading. Some of these last went far to remove misgivings expressed throughout the earlier discussions. In particular, an addition to clause 7 places inter-library copying, so far as periodicals are concerned, on all fours with copying for students, and commercial libraries are not debarred from participating in such arrangements. Lord Mancroft, indeed, anticipated that such libraries would join in the general scheme, and that articles in out-of-print scientific periodicals would figure largely in the easier copying thus made possible. The controversial clause regarding television and sound broadcasts was also clarified during the third reading and was accepted by Lord Silkin as meeting the main objection of the critics.

In his concluding speech for the Government, Lord Mancroft was able to claim with justice that the clause affecting libraries, as now amended, gives librarians the powers that the Library Association told the Copyright Committee they needed. Any widening of these provisions, he held, could only be at the expense of the copyright owner. Lord Mancroft also claimed that the clause in no way hampers librarians in exercising any rights they may now have as a result of arrangements with publishers, such as the Royal Society's fair copying declaration, or with copyright owners. The clause simply gives librarians rights which they do not possess under the existing law, and the safeguards it provides for the copyright owner operate only when these new rights are being exercised.

The Bill is not a political party measure, and the debates in the House of Lords have considerably clarified many technical issues. Some, like the syndication of articles, as Lord Silkin noted, merit further discussion and could appropriately be discussed by professional bodies of scientists and technologists before the Bill is further considered in the House of Commons. What is clear, however, is that there is still much room for clear thinking and careful inquiry and experiment as to the place of such media as broadcasting and television in the communication of ideas and in research as well as in education, quite apart from the possibilities which photo-copying itself offers for the improvement of scientific and technological communications. The Copyright Bill is both a reminder that the law of Britain needs adjustment to the new conditions which scientific advance has brought, and a challenge to creative thinking about the possibilities and implications of new powers and processes and the way they can best serve mankind.

PLANT AND ANIMAL TISSUE CULTURE

Cultivation of Animal and Plant Cells

By Philip R. White. Pp. xi+239. (London: Thames and Hudson, Ltd., 1955.) 35*s*. net.

Dr. P. R. WHITE is one of the originators of plant tissue culture. In 1934 he announced the realization of unlimited cultures of isolated roots, and then in 1939 that of tumorous tissues. Since then he has been pursuing his research on the culture of animal tissues without having abandoned the plant domain. The originality of his work is well displayed in the volume under review.

This work is a technical manual which rises above a general level when comparing methods of culturing animal tissues with those for plants. The title does not correspond exactly with the contents, for the book deals not only with the culture of true cells (at least, animal cells) but also with tissues (cambial tissue, parenchyma), with organs (embryonic organs of animals, isolated roots) and even with plant embryos. The manual thus examines all types of cultures *in vitro*, with the exception of those concerned with adult animal organs, by methods derived from that by Carrel-Lindbergh.

White recalls first of all the philosophical origins of the culture method *in vitro*, and then summarizes briefly the subsequent history. This résumé, although schematic, is nevertheless lively. The succeeding chapters deal with techniques: how the same laboratory can be adapted for culturing plant, as well as animal, tissues; and how the rooms for preparing the media, the sterilization apparatus, the rooms for inoculation, etc., are identical. Against this, the culture materials differ significantly. Plant tissues are generally cultivated in vessels that are larger than those used for animal cells. Likewise, the instruments for manipulating them are more robust. However, specialists in the culture of plant tissues adopt in certain cases the 'roller-tube method' and the small humid chambers used for animal cells. As for the nutritive media, these also are different. For plant cells they are very simple, while for animal cells they are still based on plasma and chicken-embryo extracts. White insists on synthetic solutions devised by Fisher and himself for the culture of animal cells; but these solutions are more complex than those used for plant cells.

The principal chapters of the book are concerned with methods and the principal types of culture. The author gives concise instructions which ought to be sufficient for a research worker to obtain good results. The methods for animal tissues are considered apart from those for plant tissues, and the differences between them are made clear. Furthermore, White describes in an appendix several methods suitable for a beginner. A succinct chapter deals with measurements of growth, and the work finally ends with an appraisal of the possibilities of culture methods *in vitro*. This chapter does not pretend to cover the results obtained by this technique, but merely outlines the fields which are pertinent to it: nutrition, cellular metabolism, hormonal correlations, morphogenesis, pathology and even genetics.

Only a particularly competent specialist could write such a concise, and yet complete, book. This excellent work is very timely and will replace older manuals, which are henceforth rendered obsolete.

R. J. Gautheret

WASTAGE AND ITS CONTROL

Deterioration of Materials

Causes and Preventive Techniques. (A Collaboration under the Joint Auspices of the Services Technical Committee of the Department of Defense (Contract No. *N7onr*-29127) and the Prevention of Deterioration Center, Division of Chemistry and Chemical Technology, National Academy of Sciences—National Research Council.) Edited by Glenn A. Greathouse and Carl J. Wessel. Pp. xvii + 835. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1954.) 96*s*. net.

Reviewing a lengthy reference work of this kind might well have been a tiresome business, but for the fact that the authors of the various sections have been successful in presenting a wealth of information in a pleasantly readable manner. As might be expected when so much is packed into such little compass, the data themselves are, in many cases, too brief to be adequate; but, coupled with the copious references and bibliographies which are appended to the various chapters, they provide a valuable introduction to the many aspects of deterioration with which the book is concerned.

In his preface the editor directs attention to the estimate of 12 billion dollars annually as the cost to the United States from all forms of deterioration (excluding that of foodstuffs), a very great proportion of which is attributable to metallic corrosion. It is suggested that "almost any estimate is conservative, for rarely is it possible to put a price tag on man-hours used to combat deterioration". Thus there is ample justification for a book of this kind.

The book commences with a review of world climatic variations, the chemical and physical factors arising from weather conditions and changes and, to complete Part 1, a chapter on biological agents of deterioration; this is a fascinating section in which a reader is tempted to browse. The preservation of various classes of materials such as metals, wood, paper, textiles, leather, plastics, rubber and paint is covered in the next section. It may seem surprising to find paint in this section; but, as the author points out, his is the interest "of the individual who concerns himself with the deterioration of the coating itself", and his philosophy is that the battle against deterioration of a coated article is half won if "we build into the coating the inherent ability to protect itself". Protective measures for electronic, photographic and optical equipment gained much from the experiences of the Second World War, particularly from the problems which arose in connexion with the use of this kind of equipment in the hot, humid climate of the South Pacific.

The drying and maintenance of dry conditions, packaging and the effects of toxins not only on moulds, bacteria, etc., but also as dermatitic agents, form the subjects of the concluding section. Attention is directed to the increasing use of preservatives and toxins for a wide range of materials and the consequently greater exposure of the general population to intimate contact with many complex chemicals. It is suggested that, until a proper evaluation of their toxicological properties has been established, such materials should all be regarded as potential health hazards. Finally, there is a guide to the complexities of United States specifications, including an explanation of the various codes used.

Among the various chapters, by twenty-four different authors, there is some unevenness of presentation both as to style (as would be expected) and also as to intensity of treatment. Nevertheless, the overall result is good, the book is well produced and many of the illustrations are most impressive. Each section concludes with comprehensive references both to the subject-matter in the text and to relevant publications. It is mainly concerned with the American scene; but many of the recommendations and lines of advice have a much wider application, and if followed will undoubtedly lead to the avoidance of very considerable wastage.

NEUROCHEMISTRY

Biochemistry and the Central Nervous System

By Prof. Henry McIlwain. Pp. vii + 272. (London: J. and A. Churchill, Ltd., 1955.) 40*s*. net.

With the exception of a few honourable but isolated instances, the quantitative study of cerebral metabolism was sadly neglected until the end of the Second World War. More recently, biochemical studies on the brain have proceeded apace in a number of centres, and from Prof. Henry McIlwain's laboratory at the Maudsley Hospital, London, have emerged a series of stimulating papers on the subject. It is fitting, therefore, that Prof. McIlwain should have now written a book which is both a survey of past achievements and a welcome analysis of trends in contemporary research.

The individual chapters are compact summaries of the more important aspects of brain biochemistry. After a section on the overall metabolism of the brain *in situ*, the author gives a comprehensive survey of the experimental work carried out on the labile constituents of brain tissue and their relation to cerebral activity *in vivo*. Then follows a detailed account of the information obtained from studies on the metabolism of brain tissue *in vitro*. A careful distinction is made between the results obtained with cell-containing systems (for example, cortical slices) and those obtained with cell-free systems (for example, homogenates and extracts). Other metabolic features of particular significance in the functioning of the nervous system also receive attention. Such diverse topics as the role of the vitamins and the biochemistry of the transmitter substances are treated in a manner which underlines the fundamental relationship between metabolism and function.

The reader becomes rapidly aware, however, that, whereas the chemical transformations of carbohydrates and phosphate esters in nervous tissue are known in considerable detail, information about the metabolism and function of the lipids and proteins (which constitute the greater part of the dry weight of the tissue) is sparse. The link between the metabolism of these large molecules and the activity of the brain is a rich field for future study.

Consistent with the broad view taken of his subject, Prof. McIlwain does not hesitate to discuss biochemical lesions associated with nervous dysfunction; the relevant biochemical characteristics of phenylpyruvic oligophrenia and Wilson's disease are among the topics included in the book.

Apart from the rather frequent use of sub-headings, the lay-out of the book is good and the list of references to original papers at the end of each chapter a considerable asset. The index comprises 10 per cent of the total number of pages and is exhaustive. One of the sentences on p. 238 must be a misprint, and a reference to a non-existent table occurs on p. 239. Students of biochemistry and physiology will find the book a most helpful guide to the intricacies of cerebral metabolism.

G. B. ANSELL

PHYSICS FOR THE ORGANIC CHEMIST

Determination of Organic Structures by Physical Methods

Edited by E. A. Braude and F. C. Nachod. Pp. xiii+810. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1955.) 15 dollars.

THE extent to which publishers, particularly in the United States, encourage the production of costly monographs on specialized techniques of physical chemistry is now quite disturbing; the comprehensive collection of such books is getting beyond the scope of many chemical departmental libraries in Britain, since consideration must be given to the high probability that their subject-matter may rapidly get seriously out of date. A summarizing volume on modern techniques of physical chemistry, written so as to give weight to methods of permanent value, is thus welcome, and the editors of this book deserve thanks for the way in which they have organized the collected work so as to describe essentially the principles involved and the scope of the results obtainable by applying various types of physical measurements in the elucidation of the structures of organic molecules, wisely advising that detailed accounts of particular apparatus are given literature citations only.

The book is made up of three parts, totalling sixteen chapters, and Part 1, "The Determination of Molecular Size", consists of two chapters on the phase properties of small molecules (H. F. Herbrandson and F. C. Nachod) and the equilibrium and dynamic properties of large molecules (P. Johnson), respectively. In Part 2, "The Determination of Molecular Pattern", there are five chapters: optical rotation (W. Klyne); ultra-violet and visible light absorption (E. A. Braude); infra-red absorption (R. C. Gore); Raman spectra (F. F. Cleveland); and magnetic susceptibilities (C. A. Hutchison). Part 3, "The Determination of Molecular Fine-structure", contains nine chapters on the following subjects: surface films (E. Stenhagen); dipole moments (L. E. Sutton); electron diffraction (J. and I. L. Karle); X-ray diffraction (J. M. Robertson); microwave spectroscopy (E. Bright Wilson and D. R. Lide); thermodynamic properties (J. G. Aston); dissociation constants (H. C. Brown, D. H. McDaniel and O. Häfliger); reaction kinetics (E. A. Braude and J. M. Jackman); and wave-mechanical theory (C. A. Coulson).

The names of the various contributors suffice to indicate the high quality of each section of the work. Many chapters are model essays on their subjects, delightfully readable and admirable for the breadth of their outlook. One can, however, note great differences in the extents to which individuals have visualized the problems which the organic chemists of to-day regard as matters of elucidation of molecular structure. The extremes are the chapters on applications of optical rotation measurements and on visible and ultra-violet absorption spectra and that on applications of wave-mechanics. The former two, written by experimental organic chemists, both show how physical data are of crucial value in determining the configurations of complex organic molecules of all shapes and types, with examples chosen from studies of natural products of recent interest, while the latter deals only with exact bond-lengths and electron distributions in aromatic systems—a topic which to an organic chemist has interest only in connexion with chemical reactivity.

Chapters that deal adequately with the applicabilities of their techniques are those on surface films, dipole moments, X-ray diffraction, magnetic susceptibility and thermodynamic properties. Of these, the last is noteworthy for the way in which it shows the significance of theoretical calculations in relation to conformation problems. The chapter on infra-red spectroscopy is too brief to give more than the physical background of the subject and fails to show its scope. Those on Raman and microwave spectroscopy and on electron diffraction are again highly physical, specializing on geometrical details for quite simple molecules; but of course the scopes of these techniques are essentially limited to the domain of true physical chemistry.

The long chapter on dissociation constants is over-detailed and yet tends to assume that the reader is already acquainted with both past and present theories of chemical polarity and steric hindrance. Again, the essay on chemical kinetics, in attempting to illustrate too wide a subject, assumes a background knowledge of mechanisms of organic reactions. The need for this whole chapter may be questioned, for at the present time most investigators of the kinetics of organic reactions use knowledge of molecular structure to explain details of their reaction mechanisms and not the reverse (for example, in kinetic studies of isotope replacement). In the examples given, the writers do not give due warning of the serious errors that can so easily be made by assuming that any one reaction mechanism has general validity, but do bring forward the main correlatory schemes of proved value.

Considering the extent to which each contributor has had to curtail his subject-matter to his allocated space, the wealth of information of permanent value, the excellence of its typography and, above all, its readability should ensure the book's success.

W. A. WATERS

A Monograph of the Clingfishes (Order Xenopterygii)

By John C. Briggs. (Stanford Ichthyological Bulletin—Volume 6 complete.) Pp. iv + 224 + 114 figures and 15 maps. (Stanford, Calif.: Natural History Museum of Stanford University, 1955.) 4 dollars.

The clingfishes are an order of small teleosts with an adhesive thoracic disk supported by elements of the secondary shoulder girdle and the pelvic fins. While they have no spinous rays, except perhaps in the pelvic fins, features such as the number and arrangement of the branchiostegal rays suggest that the clingfishes have sprung from a spiny-finned (percomorph) stock. But this relationship is surely not "obvious", as is stated on p. 7 of this monograph.

As a result of Mr. John C. Briggs's comprehensive survey, this order is seen to consist of ninety-three species, which can be readily arranged into eight subfamilies of the family Gobiesocidae. Twenty-one new species are described and thirteen new genera proposed, which is some measure of how little was known of these fishes, but also of the importance of this valuable, well-illustrated monograph. But Mr. Briggs's main purpose was to trace ". . . inter-relationships—hence the course of evolution—within a well-defined group of fishes, in so far as this is possible by systematic revision of a group in which fossil evidence is not available". Evolutionary trends have been followed by studying particularly the respiratory complex, the single or double nature of the adhesive disk, and the arrangement and form of the teeth. The conclusions on phylogeny are presented in the form of dendrograms—three-dimensional family trees. But in the present work, at least, it is difficult to see any particular advantage in this type of figure.

Except for certain species of *Gobiesox*, all clingfishes are marine, occurring in the coastal waters of the tropical and warm-temperature regions. In the section on distribution which concludes this monograph, two particularly interesting features emerge. The New Zealand clingfish fauna of eight species covering seven genera would seem to consist of endemic relicts, and the sub-family Gobiesocinae is not entirely confined to the New World: there is one species in South African waters.

N. B. Marshall

Theory of Ordinary Differential Equations

By Prof. Earl A. Coddington and Prof. Norman Levinson. (International Series in Pure and Applied Mathematics.) Pp. xii + 429. (London: McGraw-Hill Publishing Company, Ltd., 1955.) 64*s*.

Ince's standard treatise, "Ordinary Differential Equations", is now nearly thirty years old, so there is room for a book in English which should revise some of Ince's exposition in the light of modern methods, and extend the field of study to include an account of recent work of importance. This has been accomplished by the present authors, in a terse, compact, closely woven volume; the style is clear but stiff, and the book could scarcely be tackled by even a good honours student before his third year. The language of matrices is employed throughout, and the intending reader must be well acquainted with this language.

After two chapters on existence and uniqueness theorems, there are ten on the linear equation, with a discussion of systems with isolated singularities, and a very thorough treatment of eigen-value and boundary-value problems, singular and non-singular, self-adjoint and non-self-adjoint. The remaining five chapters supply a firm base from which to attack the important topic of non-linear mechanics, on which so much original work has been done during recent years. Asymptotic behaviour, perturbation theory and topological methods lead the reader to the focus of much present-day research; he should derive much profit from this very forward-looking volume. But he should not neglect the problems attached to each chapter; some of these are quite straightforward, but others, adding to and generalizing the text, may present a severe test of understanding. Altogether, this is a noteworthy addition to the McGraw-Hill International Series in Pure and Applied Mathematics.

Fuel

Solid, Liquid and Gaseous. By J. S. S. Brame and Dr. J. G. King. Fifth edition, rewritten by Dr. J. G. King. Pp. xii + 551. (London: Edward Arnold (Publishers), Ltd., 1955.) 50*s*. net.

It is good to see a new edition of this very useful book, especially as the previous edition was published twenty years earlier. As might be expected such a gap has made necessary the almost complete rewriting of the text, which has taken account of the changes and developments that have occurred in fuel technology in the period concerned.

It is emphasized in the preface that the book deals strictly with the properties of fuels and their methods of application, and not with details of processes of production or utilization of fuels. Nevertheless, there is a lot of helpful information on the latter aspects.

For those unfamiliar with the book it will be necessary to indicate the general scope in a little more detail. The main chapters treat the essential properties of fuels, classification of solid fuels, and give considerable consideration to the classification and composition of coal, followed by discussion of its storage and preparation, carbonization and use for generating steam, power and heat. Next are given details of the various liquid fuels used for heating and power production. There are then three chapters on gaseous fuels, one on fuel analysis, and another on determination of calorific value. The final chapter is concerned with fuel efficiency. At the end of each chapter there are references to further reading.

The volume is of attractive appearance; the matter is well expressed and well printed on good quality paper, with clear illustrations, and at present prices is very good value. It can be recommended as a very sound text-book.

Fifty Years of Birdwatching

By A. M. C. Nicholl. Pp. xx + 127 + 12 plates. (London: John Murray (Publishers), Ltd., 1955.) 12*s*. 6*d*. net.

Mr. A. M. C. Nicholl is well known as an expert bird-photographer, and he has illustrated this volume of bird reminiscences with some fine examples of his skill with the camera; but this is not a picture book, the illustrations being secondary to the text, which deals with the author's experiences down the years. In a pleasant and chatty manner Mr. Nicholl tells us of much that he has seen and done, often giving us vivid pictures of the English scene and its wild life, coupled with many a shrewd observation on birds and their behaviour.

Frances Pitt

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY, LONDON

PROPOSED EXPANSION SCHEME

Introduction by the College

THE Imperial College of Science and Technology, a school of the University of London, is made up of the Royal College of Science, the Royal School of Mines and the City and Guilds (Engineering) College. It has occupied buildings in South Kensington since 1872. Its present number of students is more than two thousand, of whom some 1,300 are concerned with technology, mainly engineering.

In January 1953 the Government asked the College to raise its student numbers (then 1,650) to 3,000 by 1962. The national need for more highly trained scientists and engineers was urgent then and is more so to-day. Recent statistics have emphasized Britain's deficiency in relation to the Soviet Union, where engineers at graduate level now leave universities and institutes at the rate of 60,000 a year, compared with 22,000 in the United States and 3,000 in Great Britain. For the purpose of the expansion the College was asked to plan on the basis of its taking over the island site, that is, the rectangle south of Prince Consort Road, bounded by Exhibition Road, Queens Gate and Imperial Institute Road.

The decision that the expansion of the College should occur at South Kensington has been generally but not universally approved. Some critics have suggested that a move into the suburbs or the country would have been preferable. This alternative was thoroughly investigated by the College between 1951 and 1953 and, in the end, there was unanimity in favour of expanding in South Kensington. The worst fate which can befall a university institution is to be split for any substantial period between two sites which are far apart. If, therefore, the expansion was to take place outside South Kensington, it would have been essential for the College to give up its existing premises. The difficulty of finding a suitable site of adequate size in the suburbs or near London was very great. Moreover, to build so large an institution in the country would have increased the capital cost enormously through the need to provide so much new residential accommodation. These were important reasons; but the decisive factors were that expansion in South Kensington enabled the College to retain and develop its close ties with the University, with the learned societies and professional institutions, and with the world of science, technology and industry. The decision, taken three years ago, was clearly right and has already led to the investment of nearly £1 million in new buildings on the site.

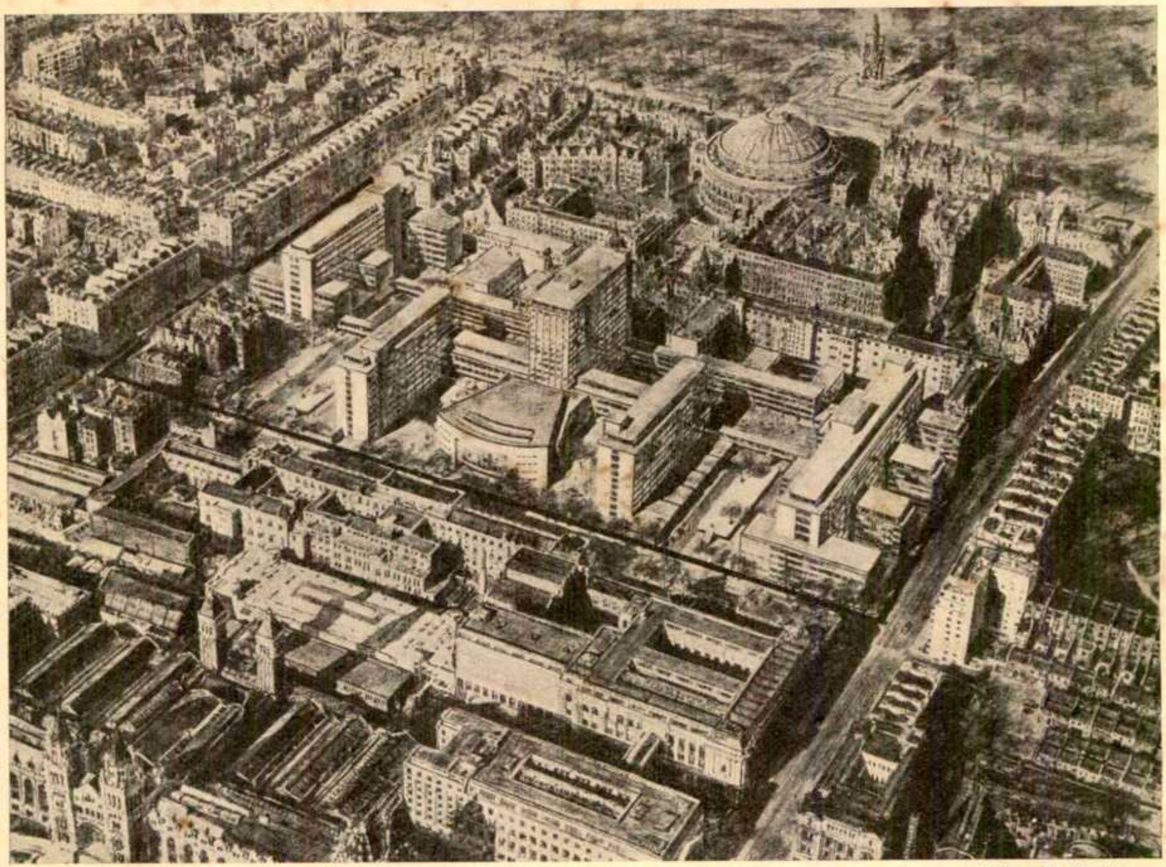
There is another reason for the College remaining and expanding in South Kensington. The surplus funds of the Great Exhibition of 1851 were invested in the purchase of the land which runs south from Kensington Gardens, on the frontage of which the Royal Albert Hall was built later; the Commissioners for the 1851 Exhibition were charged with the duty of using their resources "to increase the means of Industrial Education and extend the Influence of Science and Art upon productive industry". The use of the island site by the College is clearly in line with this requirement and with the intentions of the prime mover in these matters, the Prince Consort, who was indeed the founder and first president of the College.

The College drew up the academic plan for its expansion in 1953. On the basis of this plan it was calculated that the floor area required would be a little more than 1,800,000 sq. ft. gross (that is, including corridors, lifts, staircases and other similar space). This would give a provision of space per person of about 340 sq. ft. (gross) or about 500 sq. ft. per student. This represents an improvement on the crowded state of affairs during 1952–53, but is some way below the space available before the War (1938–39). Space requirements vary greatly according to technical equipment and these are average figures. The calculations also have to take account of the fact that postgraduates need more space than undergraduates, and that the College has the highest proportion of postgraduates of any college or university in Britain. Of the total requirement, about 340,000 sq. ft. can be provided off the rectangle by adaptations to existing College buildings in the Beit Quadrangle and the Royal College of Science building south of Imperial Institute Road. This leaves about 1,460,000 sq. ft. to be found on the island site itself.

The space is to be used as follows. Very large requirements are needed for the engineering departments, the total floor space of which will rise to about 750,000 sq. ft. Science departments, including their technological sub-departments, will rise to 500,000 sq. ft., and mining departments to 175,000 sq. ft. The College's policy is to provide a central building which will contain the common rooms, refectories, libraries and similar units; also a Great Hall. It is clear that there will be no room for residential buildings on the island site; these are to go nearby.

There are certain limitations which have to be taken into account in the planning. First, there are the normal town-planning requirements: the density of population, the angles of light between buildings, fire precautions, a sufficient area for circulation, and so on.

Next come certain special limitations: (1) It is essential that the College should be kept running during the total operation. (2) One of the largest existing buildings is more than seventy years old, and clearly near the end of its useful life; its demolition will have to be carried out as a carefully planned operation, with a progressive moving of the departments concerned into new buildings or transit accommodation. (3) It has been decided to leave intact the Royal School of Mines building and the Goldsmiths' Extension of the City and Guilds College. (4) The Royal College of Music is to be left undisturbed. (5) The development of the south-western part of the site is obscure as it contains private residences not in the College's possession. Moreover, following a request from the Royal Fine Art Commission, in 1955, the College has undertaken to preserve on æsthetic grounds the Norman Shaw house at the junction of Queens Gate and Imperial Institute Road.



Sydney W. Newbery

Fig. 1. Aerial view of the proposed expansion scheme for the Imperial College of Science and Technology, London, from the south-east. Due north is the round dome of the Royal Albert Hall facing the Albert Memorial in Kensington Gardens. Due south is the British Museum (Natural History), showing its four towers. Between this and the proposed new buildings is the Royal College of Science. To the east of the British Museum (Natural History) is the Geological Survey and Museum, and to the north of this is the Science Museum. Exhibition Road passes across the lower, right-hand corner

Messrs. Norman and Dawbarn were appointed architects for the new buildings on the island site in 1953. Mr. Graham Dawbarn presented his plan for the island site at the end of that year and it was afterwards submitted to the University and the University Grants Committee. Detailed drawings have since been made of the buildings to be erected first. The plans have been submitted to the Royal Fine Art Commission, and the 1851 Commissioners. They are now before the Town Planning Committee of the London County Council.

Description of the Scheme by the Architects

The basic scheme to implement the academic requirements of the College on the proposed site was prepared at the end of 1953 and the beginning of 1954. It is this basic scheme indicating the circulation and the general size and massing of the buildings that is illustrated by the model. Since it was made, the model has been altered only in the south-west corner to show the permanent retention of the Norman Shaw house (170 Queens Gate) and the retention for an unknown period of a block of residential property adjoining it (Fig. 2).

Three buildings, all adjoining the northern boundary of the site, are excluded from the new development: the Royal School of Mines and the Goldsmiths' Extension; the Chemical Engineering Building to which a new building—to be known as the Roderic Hill Building—is now being added for that department and for Aeronautics; and, between the two, the Royal College of Music.

The Royal School of Mines and the Goldsmiths' Extension, to which a story has recently been added, is providing essential accommodation and its removal cannot be contemplated in the foreseeable future. The Chemical Engineering Building was erected before the War; the Roderic Hill Building is now nearing completion on foundations that were formed some years ago.

The Royal College of Music, which is between the two, is fulfilling a valuable function and has one of the best concert halls in London. The wings that project on either side of it would strictly limit the height and size of any new building on its site. In the distant future it may perhaps be possible to remove it and form a sunken garden on the axis of the steps from the Albert Hall with colonnades at its southern end opening up vistas beyond; if so, drastic treatment will be required to the wings on either side.

The academic requirements necessitate very large buildings. Owing to their uses they are, in fact, large in comparison with their population. While ground space is invaluable in connexion with heavy workshops and other technical needs, some of the buildings must, to achieve the required accommodation with a measure of expansion, be very high.

The object of the Imperial College is not only to train scientists and technologists but also to form a base for education in its broadest sense. This, in London, can best be fulfilled by the students mixing among themselves and the academic staff in debate, in committee, in common rooms and refectories, and in physical and mental recreation all within the site.

The scheme, to achieve its full purpose, should be gracious and open, with sun and air penetrating the buildings and the spaces between them, with vistas from without and within, with large courts, trees, lawns, sculpture and murals so as to create an environment that will bring pride and pleasure to the occupants and to the passers-by, with 'movement' in the skylines and an avoidance of monotony and overshadowing.

The Royal College of Science building, which is to the south of Imperial Institute Road, is part of Imperial College and should be brought into the scheme. Some four or five thousand people will occupy the buildings and others will visit them. There must be adequate provision for car-parking and for vehicle circulation as independent as possible from pedestrian movement.

The buildings themselves should express their purpose and should serve future as well as present needs. They should be so flexible as to permit, over the years, changes in user and a measure of expansion within the scope of the scheme. These requirements make necessary the application of the most recent advances in structural and mechanical design and in the proper use of contemporary materials.

The site lies between relatively wide flanking roads, and a basically symmetrical layout has been found most suitable. The layout consists essentially of five 'spine' blocks, all running from north to south (Fig. 2).

Four of these blocks are 120 ft. high. The spines of the outer east and west blocks are set back some 80 ft. from Exhibition Road and Queens Gate respectively, with, between spines and roads, a series of lower spurs separated by gardens and paved terraces. The central block is 200 ft. high with low wings on either side, and, at its southern end, a Great Hall.

This orientation, coupled with the wide spacing of the high blocks, permits maximum penetration of sun and air, and provides vistas from south to north.

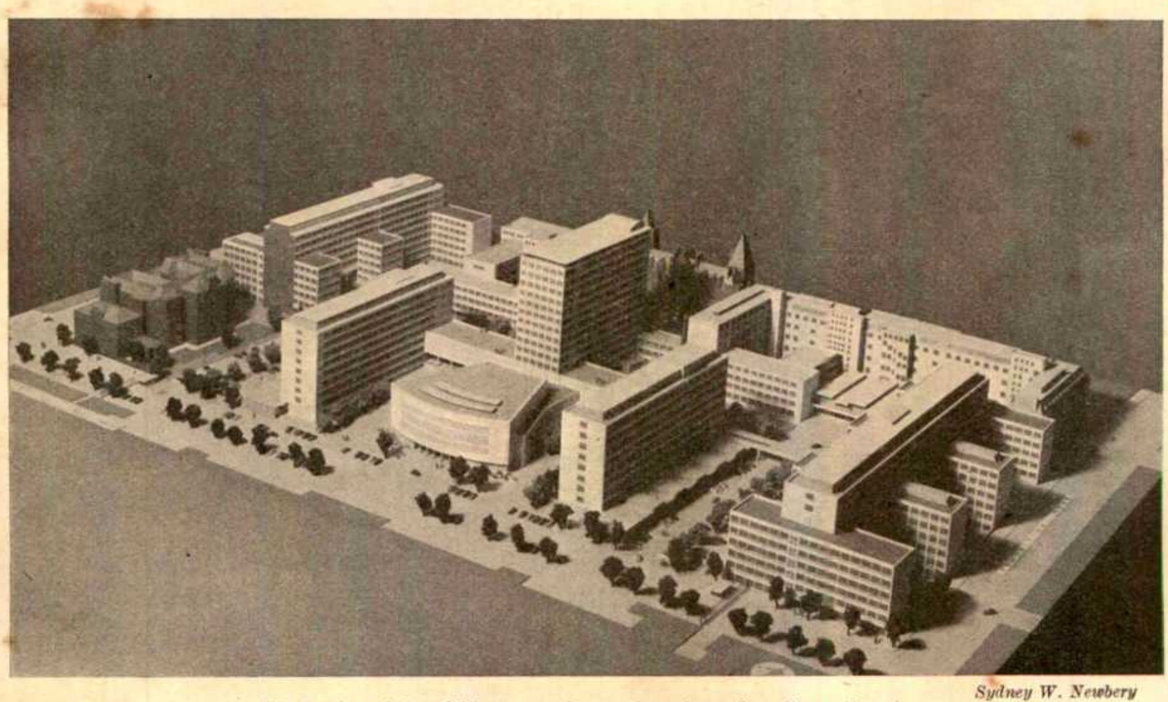
The rise of the flanking roads assists the segregation of vehicles from pedestrians. All vehicles approaching the College enter Imperial Institute Road, which it is hoped will be absorbed as a precinct as shown on the layout drawing and model. They then circulate through the courts and can make use of four traffic lanes. Parking is at the same level; partly in the open and partly under terraces and decks.

Pedestrians enter from Exhibition Road and from Queens Gate by terraces some 85 ft. wide (Fig. 3). They either enter these blocks or pass under them to emerge on to decks above covered parking, facing the central block. From these decks, bridges seventeen feet above the traffic flow lead to the inner blocks and thence on to covered decks which join a central concourse and also open on to the terraces on either side of the Great Hall.

The site has been opened-up to provide a variety of views and vistas. People travelling north along Exhibition Road, after passing two gardens, look through the pedestrian entrance under the spine of the east block to the central block more than 500 ft. away.

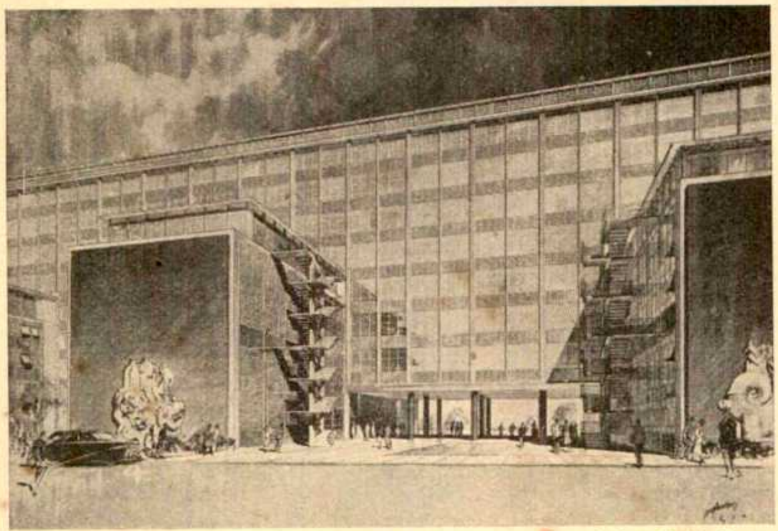
From Prince Consort Road, broad steps just west of the Roderic Hill Building look south past the west bridge to the precinct; one day a corresponding vista may be possible through the Royal School of Mines. If the Royal College of Music is ever pulled down and the site turned into a garden there will be views into the east and west courts on either side of the bastion formed by the north end of the central block—a suitable place for sculptural adornment.

The main blocks (excluding the central one) will all be devoted to teaching and research. The nucleus,



Sydney W. Newbery

Fig. 2. Amended model for proposed expansion scheme, from the south-east. The Royal College of Music (with two towers) is on the north side



Sydney W. Newbery

Fig. 3. Pedestrian entrance for exhibition rooms

composed of the central block with its wings and Great Hall, contains those elements which distinguish university life from technical training. The greatest stress is laid on the fact that these are readily accessible and that libraries, reading rooms, administration, committee rooms, debating halls and facilities for physical recreation adjoin common rooms, cafeterias and refectories. The intimate link between the departments and nucleus might later be extended to the Royal College of Science by means of bridges over the precinct and by covered ways down the edges of the low workshops which are part of the inner east and west blocks.

The nucleus may well serve three or four thousand people at one time. The covered decks under the wings (each some 55 ft. by 120 ft.) contain shops and connect directly with a large common room and with a central concourse within which lifts, escalators and staircases lead to all the components mentioned above. Cloak rooms and sanitary accommodation are necessarily included on a considerable scale ; a number of changing rooms and facilities for physical recreation are placed on the lower levels.

The Great Hall is connected with the central block at each of its several levels, but it also has entrances off the precinct and off the terraces to east and west. These terraces are open to the south and are paved for pedestrian use with groups of flowers and shrubs. They rise, by a slight gradient culminating in broad steps, from the vehicle-level of the precinct to the pedestrian-level of the covered decks. The Hall can be used either independently or as part of the College.

The model represents a basic conception. This conception still holds ; but is subject to constant analysis, development and refinement. The illustrations which accompany this note express different periods of the evolution and some or all will be amended.

The most advanced work has been done on the outer east and west blocks, which have now been designed in some detail. The remaining buildings have been planned diagrammatically to small scale but have not yet been brought to a stage at which various approvals can be obtained and working drawings started.

The Great Hall, originally planned to hold three thousand, is to be altered ; one or more smaller halls will now be provided together with other accommodation. In the southern courts, studies are in progress for providing gardens opening off the pedestrian bridges above parking areas.

MODIFICATION OF RADIATION-INDUCED GENETIC DAMAGE

By Dr. ALEXANDER HOLLAENDER and Dr. R. F. KIMBALL

Biology Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee

THERE have been many discussions of the genetic effects of ionizing radiation ; and it has often been assumed that the amount of genetic damage is determined inevitably by the amount of radiation. However, in certain circumstances, it is now possible to modify experimentally the amount of genetic damage caused by a given dose of ionizing radiation. Practical applications of this work to human hazards cannot be expected for some time, and the difficulties in predicting the eventual extent of the application are great. Nevertheless, the progress has been sufficient to warrant some optimism. For this reason, it seems worth while to review the major progress that has been made and to suggest directions in which future progress might be anticipated.

At the start, it must be emphasized that the damage done to the genetic material of the cell, the chromosomes, is a hazard not only to future generations but also to the irradiated individual himself. In fact, there are workers who think that chromosomal damage is the cellular basis of all, or nearly all, the symptoms characteristic of over-exposure to radiation. The matter is still the subject of controversy[1], but it seems almost certain that procedures that reduce chromosome damage will also reduce certain types of damage to the body as a whole.

Protective Procedures

A number of protective procedures have been developed against radiation death in micro-organisms and mammals[1-3]. This work is more extensive than that on known genetic effects, and at least some of the procedures probably act by protecting against genetic damage to the cells. Therefore, it was thought desirable to review some of the important findings as background for the genetic work.

One of the most widely used experimental means of modifying radiation sensitivity is hypoxia. If oxygen tension is decreased to below normal, the sensitivity of the organism to X- or gamma-radiation often decreases proportionally to the decrease in oxygen concentration. There is little change in sensitivity with increase of oxygen tension above normal. Thus the lethal dose (*LD*50) for mice can be changed from about 600 r. to more than 1,000 r. by putting them in an atmosphere of 5–7 per cent oxygen during irradiation[4]. This technique is not readily applicable to man because of the serious consequences of hypoxia. However, the oxygen effect is of great theoretical importance, because it indicates that there are chemical steps between the absorption of the X- and gamma-radiation and the biological damage, and these steps are subject to modification. There appears to be, at most, only a slight oxygen effect with heavy-particle irradiation.

Certain chemicals can be used to reduce the oxygen concentration. One of the most effective is sodium dithionite ($Na_2S_2O_4$), which has a strong affinity for oxygen. This compound protects micro-organisms but is toxic for mammals. One of the first compounds found to protect against death in mammals was cysteine[5], with which it is possible almost to double the *LD*50 for mice. Its protective action can be prevented by keeping animals under a slight positive pressure in high oxygen concentration[6]. This suggests that the chemical may act by decreasing the oxygen concentration in the tissues, though other suggestions have also been made[1].

A number of other compounds (glycols, glucose, succinate, alcohols) cause cells to use up oxygen by stimulating metabolic consumption. These give some protection to micro-organisms and somewhat less to mammals. Their value for protection of mammals does not seem great since they have to be present in fairly high concentration, which may be toxic. Although dangerous to use, compounds that slow down respiration, reduce blood flow, or produce methæmoglobinæmia also have some protective action for mammals, by reducing oxygen concentration in the tissues.

Of a large number of compounds reported to be more or less protective, three seem to have some promise of practical use: namely, cysteine[5], β-mercaptoethylamine (cysteamine)[7], and S,β-aminoethyl*iso*thiuronium·Br·HBr[8]. All three compounds possess both an —NH_2 group and an —SH group. The presence of both groups, separated by no more than three carbons, has been shown to be very effective[8]. The toxicity of cysteine and cysteamine at the maximally protective concentrations in mammals reduces their usefulness as protective agents. Furthermore, solutions of either are unstable to oxidation. In these respects, S,β-aminoethyl*iso*thiuronium·Br·HBr now appears, at least from studies in this Laboratory, to be the most promising. It is a stable crystalline material, and is effective when given intraperitoneally, intramuscularly, or orally. However, the compound is still sufficiently toxic to warrant considerable caution in its use, especially since most of the results have been obtained with mice. The search for compounds of the same protective power as S,β-aminoethyl*iso*thiuronium·Br·HBr and still lower toxicity is in progress. At least several years work will be required to settle questions pertinent to human application.

Recovery Phenomena

A modest amount of progress has been made during the past few years in finding means of helping the living organism to recover from radiation damage. Such recovery is a normal process, as was learned years ago by noting that mice could tolerate higher amounts of radiation if fractionated instead of single exposures were used. This applies to both lethal and non-lethal physiological effects. It is not certain whether there is actual recovery of damaged cells or simply recovery of the body from the effects of the cell death.

Survival from radiation damage in *Escherichia coli* can be increased if the bacteria are kept, after exposure, at suboptimal temperatures, especially in the presence of certain complete media[9]. These reduced temperatures slow down cell division but still allow some enzyme activity. One interpretation is that cell division utilizes so much of the enzymes and nutritional resources of the cell that the cell cannot synthesize enough of the essential compounds to sustain life. If the cell is permitted to replenish its enzyme supply and redevelop the mechanism of enzyme production before cell division is initiated, then the cell can recover from radiation damage. Evidence for this view is that the cells have a recovery requirement for certain types of extracts, such as yeast or spleen. However, other interpretations are still possible.

Post-irradiation procedures that have proved successful in mice are the transplantation or injection of spleen[10] and injection of bone marrow[11]. The treatment apparently acts by causing the damaged blood-forming tissue to recover; but it is not clear how much of the recovery is brought about by some material given off from the injected tissue and how much by direct replenishment of cells from the transplant. Evidence for functional inter- and intra-species transplantation of bone marrow from unirradiated into massively irradiated animals has been obtained by D. L. Lindsley, T. T. Odell, jun., and F. G. Tausche (*Proc. Soc. Exp. Biol. and Med.*, **90**, 512; 1955); C. E. Ford, J. L. Hamerton, D. W. H. Barnes and J. F. Loutit (*Nature*, 177, 452; 1956); and T. Makinodan (*Proc. Soc. Exp. Biol. and Med.*, in the press). However, this evidence, though suggestive, does not exclude a non-cellular recovery factor from consideration.

Many attempts have been made to isolate specific recovery substances from non-irradiated tissues; but, in mammals, no effect on recovery has been found. However, in bacteria, cell-free extracts of spleen or yeast were as effective as breis made of these tissues. The extract has been simulated by a combination of three compounds, glutamic acid, uracil, and guanine[12]. As a matter of fact, with certain strains of *E. coli*, the protection by cysteamine is dependent to about 90 per cent on the presence of these so-called recovery factors in the medium in which the bacteria are incubated after X-irradiation[13]. This interdependence of chemical protection and recovery might well be much more general than is now suspected.

It has been possible, by combining several treatments (S,β-aminoethyl*iso*thiuronium·Br·HBr before irradiation, bone marrow immediately after, and daily injections of streptomycin for ten days), approximately to triple the *LD*50 for irradiated mice[14]. However, not all effects of the radiation are equally reduced; for example, mice that recover from high doses of X-rays as a result of these treatments show early greying and loss of hair. For this reason, it is very important to find out what parts of the spectrum of radiation damage are reduced by a given treatment, and—in the present connexion—especially important to find out how much protection there is against genetic effects.

Chromosome Aberrations

One of the major effects of radiation is breakage of chromosomes. This type of damage has been discussed extensively[15]. Breakage of chromosomes can lead to death of somatic cells and also to transmissible changes in the germ cells. Two main processes are involved—breakage and reunion. According to the classic view, breakage occurs immediately and so can be modified only by treatment before or during irradiation. Reunion often requires considerable time and so may be modified by post-treatment. Actually, the idea that breakage is immediate may be partially incorrect. In any event, it has proved easier to investigate the modification of reunion than the modification of breakage, and the former will be considered first.

The most extensive analysis of reunion has been made by Wolff and his collaborators[16], using the broad bean, *Vicia faba*. They have shown that radiation not only breaks chromosomes but also inhibits reunion. Furthermore, they have demonstrated that the energy mechanisms of the cell are involved in reunion. Reunion can be delayed by enzyme inhibitors that decrease the amount of adenosine triphosphate formed, and accelerated by adding adenosine triphosphate. The importance of this substance and the long time over which the breaks can remain capable of fusing suggest that covalent bonds are involved. The same investigators have evidence for a class of breaks that reunite very rapidly. These breaks may involve the ionic bonds that Steffensen and Mazia[17] suggest exist in chromosomes. The studies of Wolff and his collaborators show that the number of two-break aberrations can be decreased by accelerating reunion through control of the metabolic processes of the cell provided that the radiation is given at a low enough rate.

The success of these or other methods for modifying reunion by post-treatments depends on the time over which breaks remain open and available for reunion. This period seems to be very different for different cells and organisms. For example, breaks have been estimated to remain open for only a few minutes in *Tradescantia* microspores irradiated late in interphase, but considerably longer in the same spores irradiated earlier in interphase[18]. Breaks induced in *Drosophila* sperm are usually stated to remain open until fertilization, although later evidence has been obtained by Baker and Von Halle[19] for some reunion in the sperm. Thus the time available for post-treatment may vary from a few minutes to several hours, or longer, and is probably different even for different tissues of the same individual.

Despite the frequently held view that breakage is immediate, several investigators[21] have suggested that a part of the breakage is not realized until after irradiation. This must be true of any breaks caused by the chromosome 'stickiness' induced by irradiation during mitosis. It would also be true if, as a few investigators have postulated, there are breaks resulting from disturbances in metabolism induced by radiation. However, the most extensive experimental support for delayed breakage is the work of Swanson and his collaborators[21], with infra-red radiation. They have interpreted their results to mean that both X-rays and infra-red radiation induce damage in the chromosomes, which can either be brought to expression by subsequent treatment with the other agent or caused to revert to normal by a heat shock. The occurrence of delayed breaks is still a matter of controversy[22]; but it is of great importance, since numerous possibilities for modifying chromosomal damage by post-treatment may be available if the breakage process really requires considerable time for completion.

In studies of delayed breakage, and other aspects of radiation cytogenetics also, it is often difficult to distinguish effects on breakage from those on reunion; this is very well illustrated by the controversies that have developed over the oxygen effect. Thoday and Read[23] first reported that the number of chromosome aberrations is markedly decreased by irradiating in the absence of molecular oxygen. As pointed out earlier, the effect of oxygen has now been found for many kinds of radiation damage, although it is not universal[24]. The early work by Thoday and Read and by Giles and his collaborators[25] led to the interpretation that part of the chromosome breaks are produced by those products of the radiolysis of water which require molecular oxygen for their formation. This interpretation still has much to recommend it as at least a partial explanation, although evidence has been obtained[26] that seems to rule out one product, hydrogen peroxide, of the radiolysis of water from consideration. Other interpretations of the chemical mechanism of the oxygen effect must also be considered in the light of the demonstration of an oxygen effect in dried materials[27].

Later work has raised a number of difficulties for the hypothesis that oxygen influences the frequency of primary breaks. These difficulties arise from observations that not all classes of aberrations are reduced to the extent expected if only the breakage process were affected. These observations have led Schwartz and Baker[19] to the view that oxygen affects reunion instead of breakage. Swanson[21] has attempted to explain the discrepancies in terms of potential breaks. Wolff and Atwood[16] have shown that the oxygen concentration during irradiation affects both the initial breakage and the subsequent reunion in *Vicia faba*. The matter is still the subject of considerable controversy, as discussions in a recent symposium[28] show.

From a practical point of view, the most important conclusion that can be drawn with certainty is that different classes of chromosomal aberrations in different cells are not affected to the same extent by oxygen. This is emphasized by the observation[29] that hypoxia does not influence the frequency of dominant lethals induced in mouse sperm. It is possible that the sperm of the mouse is normally anoxic and so is uninfluenced by hypoxia of the whole animal. However, it is not certain that this is the explanation, because there is only a small effect of hypoxia on the induction of dominant lethals in *Drosophila* sperm[19], although there is a considerable effect on the induction of other classes of aberrations in sperm and of dominant lethals in oocytes[30]. E. F. Oakberg (personal communication) has found that hypoxia and S,β-aminoethyl*iso*thiuronium·Br·HBr reduce the amount of cell death in mouse spermatogonia.

It has been reported[31] that a number of chemicals (ammonia, S,β-aminoethyl*iso*thiuronium·Br·HBr, British anti-lewisite (*BAL*), cysteine, sodium cyanide, sodium dithionite and thiourea) are able to reduce the frequency of detectable chromosome aberrations. Several of these chemicals probably act by removing molecular oxygen, but some may act in other ways. The presence of carbon monoxide or carbon dioxide during irradiation increases the frequency of aberrations[20]. The method of action is not thoroughly understood, although the respiratory enzymes of the cell appear to be implicated.

If indirect absorption of energy in the water of the cell is important, then it could be predicted that decreasing the water content of the cell would reduce the effect of the radiation. This seems to be the case in some materials[32]. In seeds of higher plants, water content has a distinct effect[33]; but the frequency of aberrations is greater at very low than at a water content somewhat higher than normal. Within the range of normal water content, the frequency of aberrations increases with increased hydration.

There is a distinct effect of temperature on the production of aberrations[22,25], but the results are complicated by the greater solubility of oxygen at low temperatures. In any event, it seems unlikely that changing the temperature will prove to be a useful procedure for reducing human hazards, although temperature studies may well add to the basic understanding of the production of aberrations.

Mutations

The major genetic changes of concern to later generations, except in relatively limited circumstances, are not gross chromosomal aberrations, but so-called point mutations. Actually, many of the changes in this category are probably small chromosomal losses or rearrangements. Thus the previous discussion of chromosome aberrations applies in large part to mutations as well.

The oxygen effect has been found for a variety of mutational changes, including recessive lethals in *Drosophila*[34] and a nutritional reversion in bacteria[35]. Protection by chemical agents has also been obtained for mutations in bacteria[18] and in *Paramecium* (unpublished work); but several workers have failed to obtain protection with cysteamine and cysteine in mice and *Drosophila*[36]. The facts that the oxygen effect is found for recessive lethals in *Drosophila* and chemical protection has been obtained for chromosome aberrations in plants suggest that there may be difficulties in getting these agents into the germ cells of animals, in unchanged form and in adequate concentration. In any event, it is obvious that there are discrepancies here which must be resolved before general conclusions on chemical protection against the mutational effects of X-rays can be drawn.

The most important question, from the present point of view, is whether mutations occur irrevocably during irradiation or are produced through intermediate steps that require considerable time for completion. There is good evidence that mutation by agents other than ionizing radiation can involve processes which require some time after the original mutagenic treatment has ceased. Thus Auerbach[37], working with the effect of mustards on *Drosophila*, has shown that some mutations do not come to stable expression for a generation or more after treatment. Also, it is known that the mutations induced by ultra-violet radiation are subject to photoreactivation[38] and heat reactivation[39] after irradiation. None of these phenomena has been found to take an important role for mutations induced by ionizing radiation.

However, there is some evidence, admittedly of a controversial or preliminary kind, which suggests that mutation by ionizing radiation, in micro-organisms at least, requires time for completion. Several workers[40] have reported delayed mutations which are expressed only after several generations of vegetative multiplication. At least a part of the phenomena may be the results of phenotypic lag, artefacts of the method of detection, and the peculiar circumstance that newly produced mutants are considerably delayed in division compared to non-mutants and old mutants. However, it is impossible to account for all the observations in this way. Recent work in this Laboratory[3,13] with certain strains of *E. coli* has suggested that the mutation process requires time for its completion. It is observed that various treatments, including post-treatments, which increase survival also decrease mutation to about the same extent. Even when allowance is made for the effects of population density, an influence of oxygen tension on mutation can be demonstrated and, though the analysis is incomplete, it seems probable that there is also a real influence of the post-treatments. Thus these observations suggest that the mutation process requires, for its completion, considerable time after irradiation. During this time it can be modified. The frequency of detectable mutations in *Paramecium* can be decreased by treatment with hydrogen peroxide after irradiation[24] and similar, though not very striking, results have now been obtained for several other post-treatments. Therefore, several pieces of evidence suggest that, at least in some cells, the induction of mutations by X-rays can be modified by treatment after irradiation.

Conclusions

Modification of the physiological damage of ionizing radiation is possible in mammals, and work is under way to apply this finding to man. However, the increased exposures which this protection might allow would have harmful genetic consequences if protection against genetic damage were not also afforded. It therefore becomes desirable to develop methods that protect against both, either by combining methods that, individually, do one and not the other, or by developing methods that will do both. The latter seems particularly feasible if, as seems probable, the cell death responsible for the physiological effects is primarily the result of nuclear damage.

The work on modification of genetic damage is, in some respects, less advanced than the work on physiological damage, and so it would be premature to make definite predictions. However, the prospects are better than many investigators would have dared hope a decade ago. The outlook is best for reducing the effects of foreseeable exposures to X- and gamma-rays since, in this case, pre-treatments could be used. Several successful pre-treatment procedures that give some promise of general applicability are already known. It is less certain that genetic damage can be modified by post-treatment following unforeseen exposures, although promising leads are available and are being investigated. Damage produced by neutrons and other densely ionizing radiations has proved less amenable to many of the procedures that are successful with less densely ionizing radiations, though the possibilities of post-treatment have not yet been adequately explored. From a practical point of view, keeping the exposure low by physical protection or avoiding the radiation are the only useful procedures at present. However, if the progress of the past decade were to continue, practical methods for reducing genetic damage in other ways might well become available. Meanwhile, this work is developing a better picture of the events involved in the induction of mutations and chromosomal aberrations by ionizing radiations, and so is providing the basic foundation upon which further developments in this field must rest.

This work is being performed under Contract No. W-7405-eng-26 for the Atomic Energy Commission.

OBITUARIES

Sir Edmund Whittaker, F.R.S.

SIR EDMUND WHITTAKER, emeritus professor of mathematics in the University of Edinburgh, died in Edinburgh on March 24. He had been for some time in failing health; but he retained to the end his mental faculties clear and unimpaired.

Edmund Taylor Whittaker, of a family which he was able to trace back through several generations (the Whittakers of Grindleton, near Clitheroe on the Ribble), was born at Southport on October 24, 1873. He was educated at Manchester Grammar School, and in 1891 went up with an entrance scholarship to Trinity College, Cambridge. In 1895, in a Tripos of great distinction, he was Second Wrangler, bracketed with J. H. Grace and followed by Alfred Young; the Senior Wrangler was T. J. I'A. Bromwich. All four of these men were destined to make a variety of contributions to mathematics. In 1896 Whittaker was elected a Fellow of Trinity College, and in 1897 he was First Smith's Prizeman. His first long paper embodied the results of his thesis, which was on automorphic functions; here, as elsewhere, his inspiration was derived in the first place from Poincaré, whom he placed very high in his pantheon of modern mathematicians.

In 1902 he published his first book, "Modern Analysis", destined in its later editions, from the second in 1915, when he had the collaboration of G. N. Watson, to have a wide influence on the teaching of functions of a complex variable and their various expansions, and almost more on the study of special functions and the differential equations associated with them. To the end of his life he preserved the keenest interest in the functions and partial differential equations of mathematical physics. In 1902 he also discovered his well-known general solution of Laplace's equation, and in 1903 he introduced the now very familiar confluent hypergeometric function, about which quite a literature has gathered. During all this time, with characteristic versatility, he had also been writing on problems of dynamics involving periodic orbits. His second book, "Analytical Dynamics", may be called epoch-making in a very precise sense, in that on the very eve of the era of relativity he summed up in rounded chapters the classical dynamics from Lagrange through Hamilton to Poincaré and Levi-Civitá. He had the gratification, and once at least the surprise, of seeing this work translated into other languages.

In 1906 Whittaker was appointed professor of astronomy in the University of Dublin, under the title of Royal Astronomer of Ireland. Though his duties pertained in a general way to astronomy, it was understood that his chief function was the strengthening of the school of mathematical physics. He therefore gave courses of advanced lectures, one of his pupils, whose future career was not to be in mathematics, being Mr. de Valéra. His principal work of these years, a work of piety and one that entailed an immense amount of reading and historical research, was his "History of the Theories of Aether and Electricity, from the Age of Descartes to the Close of the Nineteenth Century", published in 1910. This, together with its revision and amplification of 1951, and a second volume appearing in 1953 (his eightieth year) and bringing the history up to 1926 (thus just entering the Born–Heisenberg–Jordan–Schrödinger–Dirac period), must be regarded as his *magnum opus*. The last sentence of this second volume reserved for a third volume an account of later developments up to 1950; but this, though the mental power remained, the physical strength was not sufficient to carry through.

On the death in 1911 of George Chrystal, professor of mathematics in the University of Edinburgh, Whittaker was elected his successor, entering on his duties in January 1912. He held this post for thirty-five years, retiring in 1946. In Edinburgh he founded a school of research and, guided in part by the example of Runge in Germany on numerical analysis, a mathematical laboratory, at a time when this was an innovation in universities in Britain. With G. Robinson he published in 1924 a book, "The Calculus of Observations", based on the experience of the laboratory and his own knowledge of this field. Some of the incentive, and a certain part of the material, came from his contact with actuaries in Edinburgh, in particular from his close friendship with the very distinguished actuary, the late Dr. G. J. Lidstone. He will, however, be chiefly remembered in Edinburgh for his teaching, full of inspiration and flawless in delivery; he regarded it as incumbent on him to give lectures to classes at every level. At the same time, he took more than a full share in university administration and in membership of outside bodies.

On the Continent of Europe and in the United States Whittaker was very well known, and indeed kept up an extensive correspondence with mathematicians all over the globe. The mere enumeration of his honorary doctorates, fellowships, visiting lectureships or professorships, presidentships, foreign memberships and other distinctions would exceed the limits of space, and is available in any event in works of reference; much as he valued his well-deserved medals, the Sylvester, the De Morgan, the Copley and others, he appeared to be specially touched and warmed by the honorary fellowship of Trinity College, bestowed on him in his later years and reminding him of his earlier. He was knighted in 1945.

After 1930, when he was received into the Roman Catholic Church, Whittaker's interests turned to natural theology; several of his essays and books of this period, such as "Space and Spirit", have as their explicit aim the reconciliation of modern natural and cosmological science with religion. These preoccupations are a mark of the underlying seriousness of his character. In mind he was clear and rapid to a quite exceptional degree; his capacity for industry was equally beyond the normal; not least he possessed a Roman *pietas*, exercised not only in seeing justice done to the most obscure of his remote precursors in natural philosophy, but also to those close at hand, as when—to choose but one instance—he took up and edited the posthumous manuscripts of Eddington, thus producing the book, "Fundamental Theory". In manner he was unfailingly courteous, yet not formal; entirely accessible and sympathetic.

He is survived by Lady Whittaker, daughter of the Rev. Thomas Boyd and granddaughter of Sir Thomas Jamieson Boyd, of Edinburgh, and by three sons and two daughters. His second son, Dr. J. M. Whittaker, formerly professor of mathematics in the University of Liverpool, is now vice-chancellor of the University of Sheffield. A. C. Aitken

Prof. A. M. Blackman, F.B.A.

Prof. A. M. Blackman, who died at Abergele on March 9 at the age of seventy-three, was almost the last surviving member of the older generation of British Egyptologists whose researches and publications during the past sixty years have so widely extended our knowledge of Ancient Egypt and early man.

Aylward Manley Blackman was born on January 30, 1883, the eldest son of the Rev. J. H. Blackman, and until he was sixteen was educated privately. He then entered St. Paul's School, whence he obtained a scholarship to Queen's College, Oxford. Under the influence of his father, a keen amateur archæologist, Blackman had at a very early age acquired an abiding interest in Egypt and in archæology, and hence on going to Oxford it was not surprising that he should have read Egyptian, Coptic and Arabic. In 1906, he obtained a first class in Oriental studies.

Blackman's first few years after graduation were busily spent in Nubia and Egypt. During 1907–8 he was one of the assistants of the late Prof. G. A. Reisner on the first of the great expeditions of the Archæological Survey of Nubia and thus obtained practical field-experience in a very hard school. During 1909–10 he helped in the excavations by the University of Pennsylvania at Buhen, slightly to the south of Wadi Halfa, and was solely responsible for the inscriptional work of the expedition. 1910, in fact, was an intensely busy year for him. In that year he was elected Oxford University Nubian Research Scholar and participated in the Oxford Excavations at Faras, a few miles north of Wadi Halfa on the Egypto-Sudan frontier. Almost simultaneously he became one of the international team of scholars engaged in recording those of the Nubian temples that the building of the Assuan Dam threatened to submerge. Between January and May, 1910, by dint of prodigious physical effort and at the cost of sickness the effects of which never left him for the rest of his life, he recorded all the scenes and inscriptions in the temples of Bigeh, Dendur and Derr (all published between 1911 and 1915), and began but never completed the record of the temple of Gerf Hussein.

In 1912, he was elected Laycock Student of Egyptology at Worcester College, Oxford, and in the same year he began, on behalf of the Egypt Exploration Society, the copying of the inscriptions of the important group of rock tombs at Meir in Middle Egypt. His work at Meir occupied the seasons 1912–14, 1921 and 1949–50, and the results were published in a series of six volumes between 1914 and 1953.

In 1934, he was elected Brunner professor of Egyptology in the University of Liverpool, and held this post until his retirement in 1948. Academic and other responsibilities limited his opportunities of visiting Egypt; but 1936–37 saw him once again in the Sudan as director of the Egypt Exploration Society's excavations at Sesebi.

Blackman's main scientific interest was in the religion of Ancient Egypt, particularly its liturgy and ritual. Unfortunately, he never wrote a book on the subject that was nearest to his heart; but his most important contributions to Egyptology certainly lie in the numerous papers which he contributed to the leading Egyptological journals. Typical of these are his massive contributions on such subjects as "Priesthood", "Purification" and "Worship" to Hastings's "Encyclopædia of Religion and Ethics" which still retain all their freshness and value.

He was a magnificent teacher. He liked young people, and his deep knowledge of his subject, coupled with a lively and warm sympathy with and understanding of his students, made him an inspiring teacher. Above all, he was interested in showing that Ancient Egypt was alive: to him there were no dead bones in archæology, and this was reflected not only in his scientific papers, but also in his popular writings, such as his delightful "Luxor and its Temples" (1923), which was also translated into German, his "Literature of the Ancient Egyptians" (1927), a translation of Erman's original work and still the only book of its kind in English, and in his inaugural lecture, "The Value of Egyptology in the Modern World" (1936). Of all British Egyptologists, he was possessed of a real sense of style and language: his translations, even if they had perhaps rather too strong a Biblical flavour, were vivid, accurate and attractive, and his commentaries displayed that same gift of expression allied to deep learning.

Blackman's last years were clouded with tragedy and misfortune. When returning from Meir in 1950 he broke his hip on board ship, and returned home on a stretcher, only to discover that his home had been broken up by the tragic fate of his sisters. Throughout his life he had been peculiarly devoted to his family: this double blow was one from which he never really recovered, and his years of retirement were marked by increasing physical weakness and pain. His election in 1952 as a Fellow of the British Academy was a recognition of his contributions to Egyptology that brought him great cheer in his last difficult years. A great scholar, an inspiring teacher, a very human and kindly man, deeply religious, and in private life the most unselfish and sincere of friends, his death removes one of very great gifts whose place, in his own special field, it will be hard to fill.

H. W. FAIRMAN

Prof. Samson Wright

THE sudden death on March 11 of Prof. Samson Wright came as a great shock to his many friends; he was fifty-six years of age.

Samson Wright ('Sammy' to his colleagues) entered the Middlesex Hospital Medical School as a student in 1916 and, apart from one year when he was lecturer in physiology at King's College in 1929, he remained at the Middlesex until his death. After gaining the Gold Medal in the M.B., B.S. examination in 1922, he became senior demonstrator in the Department of Physiology under the late Prof. Swale Vincent, and, after his brief sojourn at King's College, he was appointed as the first John Astor professor of physiology at the Middlesex Hospital Medical School when Prof. Swale Vincent retired in 1930. In 1931 he gave the Oliver-Sharpey Lecture at the Royal College of Physicians on "Certain Aspects of the Reflex Control of the Circulation" and in 1933 he was elected a Fellow of the College.

Wright's services to physiology were many; but there is no doubt that his greatest contribution was as a teacher. Both as a lecturer and as the author of the well-known "Applied Physiology" (first published in 1926 and now in its ninth edition) he was supreme. His vast knowledge, his critical insight and his fluent exposition could make the most difficult topic seem simple, and he had a wonderful gift for stimulating others to think for themselves. He believed that physiology was the corner-stone of medicine, and his classic text-book is a vivid commentary on this theme.

During 1938–49 Wright served the Physiological Society as editor of *Physiological Abstracts*, and during this difficult time he developed it into an indispensable scientific publication.

Samson Wright made notable original contributions to the physiology of the circulation, respiration and the central nervous system. In his early work on the circulation, he was the first to show that ergotamine abolishes the response of the vasomotor centre to sino-aortic afferent impulses. His most important work on respiration was the demonstration with Selladurai that anoxic hyperpnœa is entirely dependent on chemoreceptors, whereas carbon dioxide hyperpnœa is unaffected by sino-aortic nerve section. He also studied the action of acetylcholine and related compounds on chemoreceptors and put forward the hypothesis that acetylcholine might be the transmitter substance in the glomus.

Wright worked with various colleagues for many years on the complex problem of chemical transmission within the central nervous system, and studied the actions of anticholinesterases such as eserine, neostigmine and di*iso*propylfluorophosphonate. They suggested that the differences between the central actions of the first two drugs were due to the fact that eserine is a tertiary compound which penetrates cell membranes easily, whereas neostigmine is a quaternary compound which does not.

Recently he had been investigating the effects of injection of *d*-tubocurarine into various parts of the brain as revealed by electrical wave patterns recorded from different areas.

Apart from his own work, Wright was a most inspiring and enthusiastic director of research, though he was very critical of anything which fell below his own high standards.

Wright had many interests outside physiology. He was an enthusiastic Zionist and he did all that was humanly possible to help those Jewish refugees who came to Britain from Hitler's Germany. After the establishment of the State of Israel, he took a great interest in the Hebrew University of Jerusalem, of which he was a governor. He was also vice-chairman in Britain of the Friends of the Hebrew University. He helped to build up the University's Faculty of Medicine along traditional British lines, and it is most fitting that a laboratory in its Department of Physiology was recently named after him.

In Samson Wright great intellectual brilliance was linked with a most lovable character. He was a formidable but always constructive critic, and he took a constant, unselfish interest in the welfare of his colleagues and staff. His great gift of exposition, combined with humility and sincerity of purpose, made him a most stimulating and delightful companion. His challenging personality will be greatly missed. His wife died in 1950 and he leaves three daughters.

C. A. Keele

NEWS and VIEWS

Mellon Institute of Industrial Research, Pittsburgh : Dr. E. R. Weidlein

Dr. Edward R. Weidlein retired on March 31 from the presidency of the Mellon Institute of Industrial Research, Pittsburgh, after more than forty years of active work at the Institute. Happily, his retirement will not sever his connexion with the Institute as he will remain on the Board of Trustees and will be available in an advisory capacity in the administration of the various research programmes. His successor as head of the research executive staff of the Institute has not yet been announced. Dr. Weidlein joined the Mellon Institute in 1912, becoming acting director during the First World War and then director in 1921. In 1951 he was appointed president of the Institute and, in addition, he was for four years chairman of the Board of Trustees, a post which he relinquished last year. The Mellon Institute, which is associated with the University of Pittsburgh, is an endowed, non-profit organization, conducting long-term investigations in chemical and physical technology, mainly by a system of industrial fellowships, and it is with this industrial fellowship scheme that Dr. Weidlein has been particularly concerned. However, he has also had many activities outside the Institute, and mention must be made of his work during the Second World War, as head technical consultant in the War Production Board, when he was largely instrumental in establishing the synthetic rubber industry in the United States. In Pittsburgh he is deeply interested in the health, well-being and community development of his home city and its surroundings and, in particular, in the control of industrial pollution. In 1938 the American Section of the Society of Chemical Industry awarded Dr. Weidlein the Chemical Industry Medal, and in 1948 he received the Priestley Medal of the American Chemical Society. He was president of the American Institute of Chemical Engineers during 1927–29.

Imperial College of Science and Technology : Honorary Fellowships

Honorary fellowship of the Imperial College of Science and Technology has been conferred on the following, all of whom have been connected with the College in various ways : Prof. William Brown, formerly professor of plant pathology ; Prof. Sydney Chapman, formerly professor of mathematics ; Mr. David Garnett, author, and a former student ; Dr. Willis Jackson, formerly professor of electrical engineering ; Prof. J. W. Munro, formerly professor of zoology and applied entomology ; Sir William Penney, director of the Atomic Weapons Research Establishment, a member of the Governing Body and a former student ; and Dr. W. F. G. Swann, director of the Bartol Research Foundation of the Franklin Institute, U.S.A., and a former student.

Industrial Fund for the Advancement of Scientific Education in Schools

It was announced last November that seventeen firms had agreed to form an Industrial Fund to assist in the teaching of science in independent and direct-grant schools in Great Britain by the provision of capital grants towards the building, expansion, modernizing and equipping of science laboratories (see *Nature*, November 5, p. 860). It was originally intended to raise £1,500,000 ; but seventy-three more companies have since agreed to support the Fund, and the total now subscribed from all sources is £2,900,000. The committee for administering the Fund has appointed the following four assessors to act as technical advisers both to the committee and to the schools concerned : Sir Graham Savage, formerly senior chief inspector of the Ministry of Education and thereafter chief education officer of the London County Council ; Mr. D. B. Briggs, formerly one of H.M. inspectors of schools ; Mr. W. F. Bushell, formerly headmaster of Birkenhead School ; and Mr. A. G. McKimmie, formerly headmaster of Allan Glen's School, Glasgow, whose special province is schools in Scotland and Northern Ireland.

An architectural brochure of current good practice for the building and equipping of school science laboratories has been prepared, which includes a table of standards of space and cost judged appropriate for the various types of buildings and equipment. It has been decided that, in the main, grants will be restricted to the teaching of the fundamental sciences of physics, chemistry and mathematics, that grants will not exceed two-thirds of the cost of that part of the project which is admissible for consideration, and that priority will be given to schools having 250 or more pupils over the age of thirteen and having at least 10 per cent of them in the mathematics and science sixth forms (the forms after the Ordinary Level of the General Certificate of Education). 439 schools have applied for grants from the Fund, and some interesting statistics have been compiled from their applications. In boys' schools the proportion in the mathematics and science sixth forms is now 50 per cent of the total in sixth forms, and while the total number of pupils over the age of thirteen has increased by more than a third since before the Second World War, there are now two and a quarter times as many boys specializing in mathematics and science. As a result, the facilities for teaching science are overcrowded and inadequate. Unlike maintained schools in Britain, the chief problem for independent and direct-grant schools is not a lack of science teaching staff but one of money for capital projects, and it is for this that the Fund has been created. On the basis of the applications, it has been decided to try to raise a further £600,000 to bring the Fund to a total of £3,500,000, and an appeal will be made shortly for this extra money.

United States National Committee for the Development of Scientists and Engineers

WHEN he announced, on April 3, the establishment in the United States of a National Committee for the Development of Scientists and Engineers, President Eisenhower said: "The National Science Foundation will provide staff services for the Committee and provide leadership to other departments and agencies in carrying forward activities which will contribute to a solution of the problem". The director of the Foundation, Dr. Alan T. Waterman, has recently welcomed this statement and reiterated the important part played by science and technology in the economy of the United States. Dr. Waterman emphasized that the problem of increasing the number of scientists and engineers in the United States is essentially one of educating American youth—a limited amount of education in the sciences for all young people and first-rate advanced training for the small proportion who show the necessary aptitude. Efforts must be made on a local scale all over the country, and the National Committee must stimulate non-Federal groups to encourage State and local approaches to the problem. On the national scale the various agencies of the Federal Government—notably the Department of Defense, Atomic Energy Commission, and the Department of Health, Education and Welfare—are keenly interested in the furthering of science and technology, and the National Science Foundation will co-operate with these agencies in supporting the programme of the Committee.

Scientists for Colonial Research

A QUESTION was asked in the House of Commons regarding the steps being taken to implement the proposals of the Advisory Council on Scientific Policy for home-based pools of scientists for use on Colonial problems. The Parliamentary Secretary to the Ministry of Works, representing the Lord President of the Council, in a written reply, said that such pools have been established at the instance of the Secretary of State for the Colonies at a number of agricultural research institutions and also at certain stations of the Department of Scientific and Industrial Research. Some research on Colonial medical problems is also based on the United Kingdom. A new post is being set up for research on stored products, and two pools of scientists have recently been enlarged.

Re-development of the British Museum Library

THE Advisory Council on Scientific Policy in its seventh report supported proposals for a central reference library in London or for a national science lending library, and for a science centre, of which they would form part. These proposals were not mentioned in the debate on the new British Museum Library, usually referred to as the National Library, which Mrs. L. Seger raised on the adjournment in the House of Commons on April 10, though they are related to that scheme in so far as the discarding of literature more than fifty years old is concerned. Mr. J. R. Bevins, replying for the Government, stated that under the present plans the first relatively small stage of re-development of the British Museum Library would not take place before about ten years, and that the second stage was not expected to start before 1975, and would probably be later. It would seem from these comments that the Government has no present intention of implementing the proposals for a science centre and its related library facilities.

Advisory Council of the Commonwealth Scientific and Industrial Research Organization

THE following have been appointed new members of the Advisory Council of the Commonwealth Scientific and Industrial Research Organization, Australia: Prof. N. S. Bayliss, Chemistry Department, University of Western Australia; Dr. A. R. Callaghan, director of agriculture, South Australia; Prof. H. R. Carne, professor of veterinary pathology and bacteriology, University of Sydney; Mr. T. A. Frankcomb, Tasmanian fruit- and hop-grower; Mr. A. McCulloch, chief engineer, Southern Electric Authority of Queensland; Prof. W. W. Macfarlane, Department of Physiology, University of Queensland; Mr. M. A. Mawby, vice-chairman of Consolidated Zinc Pty., Ltd., and commissioner of the Australian Aluminium Production Commission; Mr. W. W. Pettingell, general manager, Australian Gas Light Co.; Mr. W. J. Russell, Western Australian grazier; Mr. E. M. Schroder, managing director, Adelaide Cement Co., Ltd.; Mr. H. B. Somerset, managing director, Associated Pulp and Paper Mills, Ltd.; Prof. A. D. Trendall, master of University House, Australian National University; Prof. J. S. Turner, Botany Department, University of Melbourne; and Dr. J. Vernon, senior executive officer, Colonial Sugar Refining Co., Ltd.

The Scientist and Society

AN address, "The Dilemma of the Scientist", given on August 25 by Dr. J. Bronowski at the annual conference of the International Liaison Committee of Organizations for Peace, held in The Netherlands at Oosterbeck, has been published by the National Peace Council as No. 59 in the series of Peace Aims Pamphlets (pp. 10. London, 1955; 9*d*.). Dr. Bronowski points out that the main responsibility for the dangers which confront the world to-day rests on the peoples and governments and not on the scientist as such, who is not the keeper of the nation's policy. He is, however, the keeper of his own personal conscience, and Dr. Bronowski urges that governments have a duty to make it possible for the scientist to exercise his conscience and decline to participate in particular projects which are distasteful to him. Dr. Bronowski points out that, once a scientist touches the fringe of a secret subject, it is practically impossible for him to withdraw. The scientist's great responsibility, he argues, is to see that the public is sufficiently well informed on the scientific issues to vote wisely and thus secure sound decisions of policy; and a government has a further responsibility to see that scientists have the opportunity to speak freely on such issues. Dr. Bronowski concluded his address by indicating briefly the way in which the continuance of science itself as well as of a free society depends on the preservation of this right of discussion and dissent.

World List of Biological Periodicals during 1950–54

UNDER the title "Biological Sciences Serial Publications: A World List, 1950–1954", *Biological Abstracts* has published for the United States Library of Congress a list of biological periodicals that appeared during 1950–54 (pp. 270. Philadelphia: University of Pennsylvania, 1955; 2 dollars). Publications devoted entirely to medical and applied aspects of biology have been largely omitted, as "it has been estimated that if all the serials containing material on biological topics, both pure and applied, were to be included, the total number might exceed by five times the three thousand five hundred titles in the present list. The serials are grouped under five broad headings and, where possible, are subdivided according to country of origin. These headings include: general biology, botany, zoology, science of man, and general science publications containing contributions on biology or a significant number of biological papers in each issue or volume. Bibliographical details include title, issuing agency and publisher, date of first issue, frequency of publication and contents. The material comprising the regular features of a publication is classified and described as original research, analyses (including review literature and summaries of original research), proceedings of societies, conferences and congresses, abstracts, bibliographies, popular notes and book reviews. The value of this useful list would doubtless have been greatly enhanced had it included the World List abbreviations of each of the periodicals cited.

Old Akkadian Tablets from the Middle East

A CONSIDERABLE number of clay tablets have come into the possession of the Chicago Natural History Museum, and they have been deciphered by Prof. Ignace J. Gelb in *Fieldiana* (Anthropology, 44, No. 2; 1955). The writing is Old Akkadian, and internal evidence would suggest that they date to some period during 2261–2199 B.C. The tablets resemble closely some published and unpublished examples which bear the dates of Narâm-Sin and Šar-Kali-Šarrī. Unfortunately, the new tablets were obtained from an Arab, and their exact provenance will never be known. But once again internal evidence would point to the Diyala river region, and this agrees with the meagre information obtained from the Arab. The tablets (except the last two, which are letters) are texts of legal and business interest. Usually at the top are a number of proper names, and these are presumably the witnesses of the transaction given below. While they cannot be said to be exciting reading, as naturally we know nothing of the people or of the transactions, the general picture of the ordinary life and business of those times is very interesting. One of the letters at the end of the book is concerned with the slackness of a person named Ginunū who, it seems, has stopped sending bread for the soldiers. No reasons are given; but one can perhaps suppose he was a contractor of the type which has existed at all ages, and doubtless he duly sent in his bills to the head commissariat for the total amount of the bread. The volume as a whole is beautifully published, all the tablets being reproduced in half-tones.

Curtis's Botanical Magazine: Index

THE Royal Horticultural Society, London, has rendered a service that plant lovers will appreciate by the publication, under the authorship of F. J. Chittenden, of an index to Vols. 1–164 of *Curtis's Botanical Magazine*. There is also an appendix of the titles and numbers of plants from Vols. 165–170. To quote a comment in the preface: "There is little doubt that a complete set of the Botanical Magazine provides the most comprehensive and probably the most accurate collection of plant-portraits in existence though for convenience and speed of reference there has long been a need for a consolidated index to the illustrations". This very considerable task has now been completed. A major aim of providing accepted contemporary nomenclature throughout has added much to the value of the volumes that have appeared since the inception of the *Magazine* in 1787. The index and history, amounting to 282 pages, can be obtained from the Royal Horticultural Society, Vincent Square, London, S.W.1; price £2 2*s*.

Chromosome Numbers in *Oxalis*

THE genus *Oxalis*, comprising some eight hundred species, occurs principally in South America and South Africa, though some, such as *O. acetosella*, are cosmopolitan. Chromosome numbers in species of the genus have already been reported on by various investigators. The basic numbers cover a fairly wide range, namely, 5, 6, 7, 9, 11—7 being apparently the commonest. In a contemporary paper on this subject by G. E. Marks (*New Phytol.*, 55, 1, 120; 1956), the chromosome numbers of an additional twenty-six species have been ascertained, sixteen of these being of South African origin. The new data admit of cytological comparisons being made between species from the two major regions. From the total information now available the author concludes that it is possible to separate cytologically the South African from the South American group of species, the former having no variation in chromosome size, little variation in basic chromosome number but a high degree of polyploidy, while the latter group has variability in chromosome size and basic chromosome numbers with relatively little polyploidy. Using this evidence, together with morphological and ecological data, it is postulated that the South African group of *Oxalis* species is a specialized group within the genus.

The Manchester Museum

THE report of the Manchester Museum for 1954–55 is a record of quiet but steady progress made in the face of financial stringency. The rising costs of salaries and wages necessitated a restriction of all other expenditure to the lowest possible figures. Notwithstanding such an atmosphere, all departments report progress and much valuable research was carried out and published by the staff. As usual, an impressive series of twenty museum lectures was arranged for Saturday afternoons, with an average attendance throughout the year of sixty-five. At the annual reception the Museum welcomed about three hundred guests, and the idea of showing them special displays of recent acquisitions and illustrating the scientific and technical work done in the Museum is to be commended.

Commonwealth Fund Fellowships

THE Committee of Award of the Commonwealth Fund Fellowships has made the following elections, among others, for 1956–57: *General Fellowships*: H. G. Alexander, Aberdeen, Christ Church, Oxford, and Manchester (philosophy); J. A. Beardmore, Sheffield (genetics); J. S. Cumpsty, Durham (mining); Miss Marion Fairman, Durham and Glasgow (bacteriology); W. Galbraith, Birkbeck College, London (physics); Miss Janet Graham, St. Andrews (botany); N. Macleod, Imperial College, London, and Leicester (chemistry); J. McDaniel, Imperial College, London (engineering); J. N. Murrell, King's College, London, and Corpus Christi College, Cambridge (physics); H. M. A. Onitiri, London School of Economics (economics); D. F. Shaw, Manchester (chemistry); J. G. Taylor, Christ's College, Cambridge (mathematics). *Home Civil Service Fellowships:* E. Y. Bannard, Ministry of Transport and Civil Aviation; A. A. Bellamy, Ministry of Housing and Local Government; R. W. Howe, Department of Scientific and Industrial Research; E. H. Simpson, Ministry of Education. *Oversea Civil Service Fellowship:* W. J. A. Payne, Fiji (animal climatology).

University of London: Appointments

The following appointments have been made in the University of London: M. W. Humphrey Davies, reader in electrical engineering in the Imperial College of Science and Technology, London, to the University chair of electrical engineering tenable at Queen Mary College; Dr. E. Shotton, senior lecturer in pharmaceutics in the School of Pharmacy, London, to the University chair of pharmaceutics tenable at that School; Dr. O. S. Heavens, lecturer in the University of Reading, to the University readership in experimental physics tenable at the Royal Holloway College; Dr. H. B. Henbest, lecturer in organic chemistry in the University of Manchester, to the University readership in organic chemistry tenable at King's College; Dr. J. C. Pugh, senior lecturer in the Department of Geography, University College, Ibadan, to the University readership in geography tenable at King's College; and Dr. A. J. B. Robertson, lecturer in physical chemistry, King's College, to the University readership in physical chemistry tenable at that College.

Oversea Service Division, Colonial Office

The following appointments have recently been made in the Oversea Service Division, Colonial Office: J. D. Broatch (deputy director of agriculture, Gold Coast), director of agriculture, Gold Coast; E. J. Butler (senior agricultural officer, Northern Region, Nigeria), principal research officer, Northern Region, Nigeria; I. W. Hughes (plant pathologist, Bermuda), assistant director of agriculture, Bermuda; R. A. Kitching (agricultural officer, Gambia), senior agricultural officer, Sierra Leone; L. N. H. Larter (senior botanist, Federation of Malaya), chief research officer, Federation of Malaya; H. K. Ashby, E. J. H. Berwick, J. Cook, W. N. Scott and H. J. Simpson (senior agricultural officers, Federation of Malaya), senior agricultural officers, grade A, Federation of Malaya; J. B. G. S. Staub (sugar technologist, Mauritius), registrar, Central Board, Mauritius; D. G. Cumming (senior assistant conservator of forests, Northern Rhodesia), conservator of forests, Northern Rhodesia; D. H. L. Rollinson (veterinary research officer, Uganda), chief veterinary research officer, Uganda; O. S. Barr, agricultural officer, Uganda; J. V. Huhta, mining geologist, Sierra Leone; W. J. Bell, special grade medical research officer, West African Council for Medical Research; A. J. MacLeod, veterinary research officer, Federation of Nigeria; A. C. Brooks, biologist, Game Department, Uganda.

Announcements

The Earl of Iveagh, chancellor of the University of Dublin and Trinity College, will open the reconstructed Iveagh Geological Laboratory in the College on May 10.

The Right Hon. Sir David Eccles, Minister of Education, will open the extensions to the Northampton Polytechnic, London, on May 7.

Mr. G. H. C. Amos, a principal in the Ministry of Agriculture, Fisheries and Food, has been appointed agricultural and food adviser to the High Commissioner for the United Kingdom in Ottawa.

The Development Commission is offering two or three training grants to British honours graduates for training in research problems in marine or freshwater science, which is designed to fit them for employment either in the Fishery Research Service of the Ministry of Agriculture, Fisheries and Food and the Scottish Home Department or in a marine or freshwater biological research institute. The grants are worth £250–£350 a year, with allowances for university fees, etc., and are tenable for one year initially, renewable up to a maximum of three years. Application forms, to be returned by May 20, and further information can be obtained from the Secretary, Development Commission, 3 Dean's Yard, London, S.W.1.

The annual conference of the Electron Microscopy Group of the Institute of Physics will be held in the University of Reading during July 24–26. Papers on all aspects of electron microscopy, both theoretical and practical, together with applications of the instrument are invited. Further information can be obtained from the Assistant Secretary, Institute of Physics, 47 Belgrave Square, London, S.W.1.

A conference on the science and technique of photography, organized by the Scientific and Technical Group of the Royal Photographic Society, will be held on May 12 in the Institute of Physiology of the University College of South Wales and Monmouthshire, Cardiff. The conference will be open to all, without admission ticket. Further information can be obtained from the honorary secretary of the Group, R. J. Cox, Ilford, Ltd., 134 St. Albans Road, Watford, Herts.

The Electronics Section of the Scientific Instrument Manufacturers' Association is holding an exhibition on "Atoms, Electrons and Industry" in the Royal West of England Academy, Bristol, during June 6–8. Twenty-nine firms will be participating and also the Atomic Energy Authority, Harwell, and the University of Bristol. The aim of the exhibition is to acquaint industrialists with the progress being made by British instrument firms and, by showing applications already in use by some industries, to stimulate other industries to find further uses for these new tools. Admission will be free, by ticket only, applications for which should be made to the Association, 20 Queen Anne Street, London, W.1.

An international light metals convention will be held at the Montanistische Hochschule, Leoben, Austria, during June 7–9, when, as in the case of the previous two conventions there in 1934 and 1948, a survey will be given of the present state of the development of light metals. Lectures will be given by leading experts from Europe, Canada and the United States, and will cover the following fields: light metals in the national and world economy; metallurgy of light metals (aluminium and magnesium); the development of titanium; technology of light metals; metallography and physics of light metals; and the application of light metals. A programme has been published, and this and further information can be obtained from the Geschaftsstelle der 3 Internationalen Leichtmetalltagung, Leoben/Stmk., Austria, Montanistische Hochschule, Institut für Metallkunde.

ATOMIC SPECTROSCOPY

SYMPOSIUM AT THE ARGONNE NATIONAL LABORATORY

DURING February 15–17 a symposium on spectroscopy was arranged by the Argonne National Laboratory, Lemont, Illinois, which is one of the research centres (administered by the University of Chicago) of the United States Atomic Energy Commission. Many contributors to the meeting were either members of the Commission or were doing work under contract for it; but the symposium was concerned with non-classified subjects of optical research and gave an opportunity for seeing current developments in the United States.

Emphasis at the meeting was put on general research rather than on spectrochemical techniques. However, a few papers dealt with such problems. D. W. Steinhaus (Los Alamos) discussed the problems of a high-resolution spectroscopy laboratory when radioactive materials are involved. The view that the poor reproducibility of the porous-cup source is caused by inhomogeneous porosity of the graphite was expressed by M. Slavin (Brookhaven); quicker and more reliable results have been obtained by use of water cooling and a lacquer coating. A paper on the spectrographic determination of oxygen in metals (in particular, iron) was presented by R. W. Tabeling and V. A. Fassel (Iowa State College), who showed that with d.c. carbon-arc excitation and argon as an internal standard, reliable results (to about 20 p.p.m.) can be obtained.

L. Wilets (Los Alamos) discussed isotope shifts and nuclear structure, and pointed out there are three main observations which theory should explain. The observed shifts are on the average too small, show regular variations with neutron number and exhibit even–odd staggering. A possible explanation for these experimental facts may be connected with compressibility and deformation of the nucleus. W. M. Cloud, J. E. Mack and J. A. Vreeland (Wisconsin) discussed experimental isotope shift data for palladium-46, cadmium-48, tin-50 and tellurium-52. L. E. Owen and D. C. Manning (Goodyear Atomic Corporation) described the narrow wave-length interval direct-reading spectrometer being built on the principle of conversion of photoelectric currents into pulse counts. Techniques used by F. S. Tomkins and M. Fred (Argonne) for spectroscopic examination of small radioactive samples were outlined; such methods include high-frequency discharge sources and porous electrodes, and the spectra are obtained on a 30-ft. Paschen–Runge grating mounting.

The nuclear dipole moment (μ) and the electric quadrupole moment (Q) have been determined by T. E. Manning, M. Fred and F. S. Tomkins (Argonne) from consideration of the hyperfine structure of certain lines and a partial term analysis of americium-I and -II. The values are given as $\mu = +1{\cdot}4$ nm. and $Q = +4{\cdot}9 \times 10^{-24}$ cm.^{2} for the isotope 241. The corresponding quantities from isotope 243 agree within 1 per cent. J. G. Hirschberg (Wisconsin) described a photoelectric method for examining, with the use of a Fabry–Perot interferometer, the Lamb shift in ionized helium (excited from a liquid-helium cooled source). A similar investigation on lead isotopes has been carried out by J. Brody (Argonne), who also discussed the relative effectiveness of metal and dielectric coatings in interferometers. Isotopic analysis of polonium-208 and -209 mixtures by measurements of intensities of band heads from the molecules $(^{208}\mathrm{Po})_2$ and $(^{208}\mathrm{Po}\ ^{209}\mathrm{Po})$ was discussed by D. J. Hunt and G. Pish (Monsanto). V. W. Cohen (Brookhaven) pointed out that optical methods for studying nuclear properties should still be considered together with the more modern techniques such as those involving microwaves and atomic beams; he gave a list of radioactive elements which could profitably be studied. G. W. Stroke (Massachusetts Institute of Technology) and F. H. Sullivan and D. K. Rice (Jarrell-Ash) gave theoretical and experimental criteria for measurement of the performance of a diffraction grating and maintained that wave-front interferograms give most information on this matter.

Studies of hyperfine structure are sometimes rendered difficult because the lines are broadened by the Doppler effect. F. Bitter (Massachusetts Institute of Technology) discussed general methods of overcoming this problem by such means as atomic beams in electrodeless discharges at low pressures. A method involving coincidence counter techniques was proposed by P. L. Sagalyn (Massachusetts Institute) for considerably reducing the effect; the photons of two lines are simultaneously detected by coincidence techniques, and the difference in wave-lengths is independent of the Doppler effect. If a mercury arc is placed in a magnetic field, the wave-lengths of the hyperfine structure components of the lines emitted are a function of the field. One of the components can be used as a variable wave-length source for the study of hyperfine structure in absorption. H. H. Plotkin and J. E. R. Young (Massachusetts Institute) gave papers in which this technique was used for the study of the mercury $^3S_1$ state and the resonance lines of mercury radioisotopes, respectively; a similar principle was used by P. L. Sagalyn for some radio-frequency experiments in the mercury $^3P_1$ level.

A session on term analysis was opened by G. H. Dieke (Johns Hopkins University), who discussed a semi-automatic method for spectroscopic wave-length and intensity measurement; the spectral lines are displayed on an oscilloscope screen and the comparator readings recorded electronically, much of the tediousness and strain of measurement being thus eliminated. L. F. H. Bovey (Harwell) described a furnace which can be used for obtaining the absorption and emission spectra of neutral atoms of radioactive elements such as plutonium. The analysis of praseodymium-I was discussed by S. P. Davis (Massachusetts Institute), who emphasized the use made of Zeeman patterns (taken at fields of 79,000 oersteds) of neutral atoms excited by an electrodeless microwave discharge source. The lines were recorded on an echelle spectrograph. Similar experiments on erbium have been carried out by J. W. Lindner and S. P. Davis (Massachusetts Institute). C. C. Kiess and R. Zalubas (National Bureau of Standards) gave details of a comprehensive programme being carried out on thorium-I. The term analysis of this atom may show when the $5f$ electron enters the configuration of valence electrons in the heavy elements. Some twelve thousand lines have been measured in this work, and while not all are thorium-I, it is estimated that it will take at least three years to finish the analysis. In describing the application of new techniques to Zeeman spectroscopy, P. M. Griffin and K. L. Vander Sluis (Oak Ridge) showed how a combination of electrodeless discharge sources, very uniform magnetic fields of about 33,000 oersteds and an echelle spectrograph can produce very well-resolved Zeeman patterns; results off the plates were obtained with the aid of a high-speed electronic computer (Oracle).

H. H. Nielsen and K. N. Rao (Ohio State University) discussed measurements connected with the theory of centrifugal stretching constants in linear polyatomic molecules. The results from an analysis of the absorption spectrum of thallous chloride taken with a Fabry–Perot interferometer crossed with a 21-ft. grating instrument were given by R. R. Kadesch, J. C. Moldenhauer and J. G. Winans (Wisconsin); and G. W. Charles (Oak Ridge) discussed the vibrational analysis of the spectrum of Po_2. The use of absorption and fluorescence spectra to derive the symmetry of the micro fields about europium ions in methanol (C_{2v}) and in water (D_{3h}) was described by S. Freed, E. V. Sayre and D. G. Miller (Brookhaven). Further results from the polarization, absorption and fluorescent spectra of single crystals at temperatures between 4° and 300° K. of some praseodymium and europium salts obtained by Freed and Sayre give much information on the micro-crystalline fields surrounding the ions.

After a discussion of the derivation of selection rules for rare-earth ion spectra in crystals, R. A. Satten (University of California) showed how these are violated in the spectra of neodymium bromate and ethyl sulphate. The breakdown in the selection rules is partially attributed to interaction of electronic and vibrational motion. The possible electronic configuration of the Am^{+3} ion was briefly discussed by J. G. Conway, R. D. McLaughlin, B. B. Cunningham (Berkeley) and D. M. Gruen (Argonne) following a description of the experimental absorption (over the range 3000–12,000 A.) and fluorescent (range 3000–8800 A.) spectra of single crystals of lanthanum chloride containing 0·04 and 0·2 mole per cent americium chloride. The Raman spectrum of uranium hexafluoride and the infra-red spectra of neptunium hexafluoride and plutonium hexafluoride have been observed by J. K. Brody, H. H. Claassen and B. Weinstock (Argonne), and all six fundamental frequencies arising from the O_h symmetry determined. The absorption spectra of the last two fluorides have also been studied between 5000 and 25,000 A., and an interpretation of the fine structure seen in some of the bands was discussed.

K. W. Meissner and E. C. Finckh (Purdue University) discussed the possible use of a calcium atomic-beam lamp for high-precision measurements of wave-length. A half-width of 9×10^{-3} cm.$^{-1}$ was observed in preliminary experiments. A complete and consistent set of oscillator strengths for dipole transitions from the ground-level of the helium atom were given by W. F. Miller and R. L. Platzman (Purdue). From a study of the unusual Doppler effects in calutron ion sources, J. R. McNally, jun., and M. R. Skidmore (Oak Ridge) showed that these should be attributed to an ordered ionic drift about the arc column with ion velocities often exceeding 10^6 cm./sec.

The use of nuclear magnetic resonance to determine isotope ratios ($^1H/^2H$ and $^6Li/^7Li$) was summarized by B. E. Holder and M. P. Klein (California). The techniques described included both a relative and an absolute method. The natural $^7Li/^6Li$ ratio was found to be 11·8. The same authors also discussed measurement of nuclear magnetogyric ratios by nuclear magnetic resonance. Where direct observation is not possible because of such causes as residual atomic paramagnetism, nuclear quadrupole interaction, low abundances or small magnetogyric ratios, a double resonance technique can be tried. In this method the atom under investigation is bonded to an atom with more favourable properties. Under suitable conditions, by an indirect spin–spin interaction, the constants of the unknown atom can often be determined. L. S. Goodman (Argonne), in a paper on atomic beam measurements of radioactive isotopes, discussed problems connected with the source, magnetic field, calibration and detection.

Much of the work discussed was in the course of publication or had been published, and therefore no arrangements were made for issuing any detailed account of the symposium.

L. F. H. Bovey

PHYSIOLOGY OF FUNGAL PARASITISM

STUDIES of the physiology of fungal parasitism, begun by Prof. W. Brown many years ago at the Imperial College of Science and Technology, are being maintained and extended, special attention being given to the part played by the enzymes which bring about the dissolution of the cellular structure and the death of tissues. In the *Annals of Botany* (20, 77; 1956) three investigations are reported. J. S. Cole gives an account of the pathogenicity of *Botrytis cinerea*, *Sclerotinia fructigena* and *S. laxa*, with special reference to the action of their pectolytic enzymes. He has found that although these three fungi cause rotting of apple tissue and the death of the protoplasts, very little pectolytic activity can be detected in the rotting tissue.

Pectolytic activity was measured by methods involving (*a*) maceration of plant tissues, (*b*) viscosity and reducing group determinations in pectic substrates, (*c*) increase in acidity of pectin. By these methods it was shown that pectolytic enzymes were produced by all three fungi in synthetic media. With *S. fructigena*, which was the only fungus studied in detail, replacement of glucose by pectin increased the formation of pectolytic enzymes. When various apple extracts were used as culture media, little or no pectolytic activity was detectable. With all three fungi the presence of apple juice in a culture medium, which by itself was suitable for enzyme formation, resulted in the suppression of pectolytic activity. Oxidized apple juice had a pronounced effect in deactivating certain pectolytic enzymes, an effect which was especially marked with *B. cinerea*. This points to an interaction between the pectolytic and oxidizing systems and introduces a new line of approach to the study of the biochemical interaction between host and parasite.

R. K. Singh and R. K. S. Wood, in an investigation of the production and properties of the pectic enzymes secreted by *Fusarium moniliforme*, have observed that this fungus secreted macerating enzymes in liquid media only when these contained certain natural extracts, pectic substances, or galacturonic acid. Apple extract was unsuitable for enzyme secretion and also inhibited enzyme secretion in synthetic media otherwise suitable. Protopectinase activity of solutions was highest in the *p*H range 8·0–9·0, was rapidly lost at temperatures above 50–60° C., and was reduced by concentrations of phosphate higher than 0·02 *M*. The enzyme was partially purified by precipitation in 60 per cent acetone at *p*H 6·0. Protopectinase solutions also contained an enzyme which reduced the viscosity of solutions of various pectic substances. The properties of this enzyme were, in general, similar to those of protopectinase. When activity of enzyme solutions was measured by the liberation of reducing groups, pectate solutions were more rapidly degraded than were solutions of a high methoxyl pectin, particularly in the early stages of the reaction. Partition chromatography of the products formed showed that pectate and pectin were degraded in different ways. Although the pathogen readily secreted protopectinase in potato extract, potato tubers were not readily parasitized. In contrast, *Fusarium avenaceum*, which readily attacked tubers, secreted little protopectinase in potato extract.

S. C. Gupta has examined the production of pectolytic enzymes by *Pythium de baryanum*. Among other things, he observed that the incorporation of sodium chloride in a synthetic medium stimulated the pectolytic activity of cultures of *Pythium de baryanum*. The chloride ion appeared to be mainly responsible for this effect; on the other hand, presence of the calcium ion depressed enzymic activity. Glucose, fructose and mannose were about equally suitable for growth and enzyme production. Sucrose, if used as sole carbohydrate source, gave good mycelial growth but poor enzyme production; but if a small proportion was replaced by glucose, enzyme production was as good as on glucose itself. Galactose gave very poor growth and negligible enzyme production. For optimum production of pectolytic enzyme, glucose (or fructose or mannose) requires to be autoclaved in a somewhat alkaline medium—very conveniently with the dipotassium hydrogen phosphate or potassium phosphate of the nutrient medium. A yellow to brown coloration (due to caramelization) is produced in the process; but the stimulating factor is not bound up with the colouring substance. The same stimulating effect on enzyme production was obtained by adding to the nutrient medium a small quantity of glucose which had been dry-heated at 150° C. for 20 min. Partition chromatographic analysis suggested that the stimulating substance was probably glyceraldehyde, though it is not excluded that other breakdown products of sugars may also play a part.

CARNEGIE TRUST FOR THE UNIVERSITIES OF SCOTLAND

REPORT FOR 1954–55

THE fifty-fourth annual report of the Executive Committee of the Carnegie Trust for the Universities of Scotland, covering the academic year 1954–55*, records an increase in the numbers of students from 1,408 to 1,502, chiefly in science and medicine, to whom assistance was given with their class fees, the amount expended increasing from £22,007 to £24,232. Problems created for the Trust by the bursary awards made by local education authorities in terms of the Education (Scotland) Act are by no means solved, and the Executive Committee directs attention to the, apparently, growing assumption of many students that the Carnegie Trust grant is to be applied for as an addition to the education authority bursary, whatever be the value of that bursary. Strongly emphasizing its declared intention to limit its assistance in this direction to holders of local education authority bursaries whose circumstances, taken as a whole, appear genuinely to warrant additional help, the Executive Committee expresses its desire for a proper appreciation of this policy and the reasons for it on the part of directors of education, university advisers of studies and similar officials.

Expenditure on the Trust's research scheme totalled £33,155, and its various features were maintained. Three senior scholarships and fifty-three scholarships were awarded or renewed, some being supplements to scholarships and bursaries gained from other sources, and twenty-three of these were used for postgraduate study outside the parent university. The high value of this part of the programme is stressed in the report, as is that of the scheme, inaugurated in 1950, which affords annually ten members of university staffs, more than thirty years of age, the opportunity of study abroad. Eleven such awards were made in 1954–55, three being in scientific subjects, two in medicine and one in African studies. Besides the annual grant made to the Royal Society of Edinburgh and to the *Scottish Historical Review*, eleven learned societies in Scotland were assisted in the publication of their transactions and journals; in addition to an immediate grant of £2,000 to the Scottish National Dictionary, the Scottish Dictionaries Joint Council was invited to submit plans by which £20,000 could be used for ensuring substantial developments within a reasonably short period, and this sum has been placed at the Council's disposal. Repayments by former beneficiaries declined slightly from £1,921 from thirty-six former beneficiaries to £1,868 from thirty-three beneficiaries.

Besides particulars of grants made under the ninth quinquennial distribution, October 1, 1952–September 30, 1957, there are appended the terms of the scheme for the endowment of postgraduate study and research and a summary of reports received from the advisers to the Trust on the work of investigators under the research scheme during 1954–55. In the mathematical, physical and engineering section, the fellowships of R. Giles on quantum field theory at the Institute of Theoretical Physics, Copenhagen, and of D. Chisholm on the flow of two-phase mixtures at the University of California are stressed as outstanding. K. M. Swanson's work on nuclear magnetic resonance was again successful, and in connexion with J. V. Thomson's work in fluid dynamics it is suggested that the Scottish universities should co-operate to provide an electronic computer with the strong support of the Carnegie Trust.

In the chemistry section, J. S. S. Reay, working on organic ammonium derivatives of montmorillonite, has noted interesting relations between the molecular volume of the ammonium ions and the adsorptive capacity for hydrocarbons. J. M. Beaton's work at the Royal Technical College, Glasgow, has been instrumental in establishing the constitution of taraxerol; also, by establishing the orientation of the carboxyl group in glycyrrhetic acid, he has completed the determination of its stereochemical configuration and has effected the first direct conversion of a member of the ursane triterpenoid group into an isomer of the oleanane group. Miss H. Kerr's successful work on the algae of the highest life zone of the shore at the Marine Station, Millport, and G. K. Wallace's work, in the Anti-Locust Research Centre Laboratory of the Entomology Department, Oxford, on the influence of light and of observable objects on the movements of locusts, are also noted, as well as that of Dr. S. M. Marshall and A. P. Orr on the distribution, anatomy, reproduction, development and life-cycle of the small crustacean *Calanus finmarchicus* (Gunnerus). Continuing his gravity survey in Scotland, Dr. J. Phemister covered the whole of Fife and Scotland south of the Forth–Clyde, and W. G. Jardine continued his researches at Cambridge on the relation between shore-lines and river-valley development, with particular reference to the Southern Uplands. D. H. Mackenzie commenced a structural and petrological study of the granite and associated rocks of Mid-Strathspey, and D. I. Smith a similar study of the third ring dyke complex of Ardnamurchan.

The usual lists of publications by fellows, scholars and recipients of grants and of awards under the research scheme during the year are also appended, together with the financial accounts.

FLOW OF VISCOUS LIQUIDS IN BRANCHED TUBES

WITH REFERENCE TO THE HEPATIC PORTAL VEIN

By Dr. C. H. BARNETT and Dr. W. COCHRANE

Department of Anatomy and Department of Physics, St. Thomas's Hospital Medical School, London

THE existence of independent stream-lines within the hepatic portal vein[1] may account for the localization of disease processes within certain parts of the liver[2]. Before conclusions drawn from animal experiments can be applied to man, however, anatomical and physiological differences need to be considered. In different species, the tributaries and branches of the vein vary with respect to diameter and angle of junction; moreover, the relative rates of flow and viscosity of the circulating blood probably show species variations. To investigate the significance of these differences, experiments have been carried out on non-turbulent flow for the following typical junctions: a minor branch leaving a straight main tube; a minor tributary joining a straight main tube; and major and minor tributaries uniting to form a main tube. The aim has been to determine the region of the main stream which feeds the branch in the first case, and the region of main stream receiving from the tributary in the second and third cases. Some answer can then be given to the question: What are the chances that particles (bacteria, malignant cells, etc.) suspended in the blood leaving an organ and entering the portal vein will be eventually directed into a particular region of the liver ?

The liquids used were (1) water and (2) 40 per cent glycerine in water (specific gravity 1·100), referred to below as 'glycerine'. The viscosities of these liquids at room temperature (19°–21° C.) were (1) 1·0 and (2) 3·5 centipoises, approximately that of human blood[3]. The tubes were of 'Perspex', cut and drilled as necessary, and cemented together so as to give sharp internal edges at the junctions. Unless otherwise stated, the internal diameters of the main tube and the wide and the narrow branches or tributaries were 10, 8 and 6 mm., respectively. The lengths of all the tubes from the junction were sufficient to ensure that the steady parabolic velocity profile was usually at least 99 per cent developed. By means of a large opal lamp and a lens, the system under investigation was projected on to a white screen and measured at a magnification of × 8. Corrections for optical distortion were applied. No elaborate investigation of the scaling of tube dimensions has been attempted, but it appears that the results are valid for other dimensions of tubes if the ratio of diameters remains unchanged. When flowing in tubes of diameter exceeding 0·4 mm., blood can be regarded as a continuous medium[4].

For flow into a branch from a straight main tube, the apparatus is shown in Fig. 1*a*. Flow-rates were adjusted by constricting the two exits. The position of a stream-line in the main tube was shown by a fine line of coloured liquid (Evans blue) from a quill tube, the position of which was controlled by a micrometer screw. When the rates of volume flow, Q_s in the branch and Q_m in the lower part of the main tube, were steady, the position of the coloured stream-line was adjusted until it just failed to enter the branch. The distance x of this critical stream-line from the wall of the main tube was measured (Fig. 1*a*). Graphs of Q_s/Q_m against x were drawn, x being expressed as a percentage of the diameter of the main tube. Some results are shown in Fig. 2. Each curve is the result of thirty or more observations and is probably accurate to ± 5 per cent. The results were independent of the total flow-rate. It was concluded that, for a given value of Q_s/Q_m, the chances that particles in the main tube remote

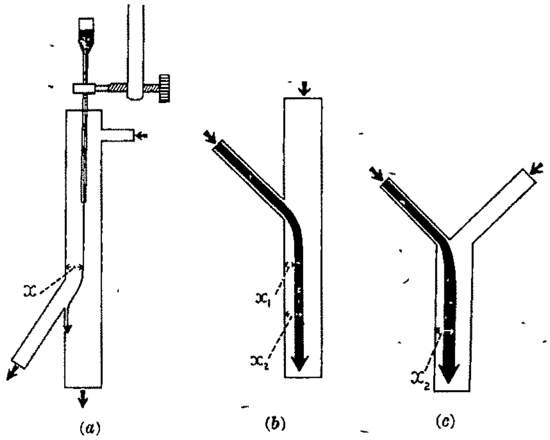

Fig 1

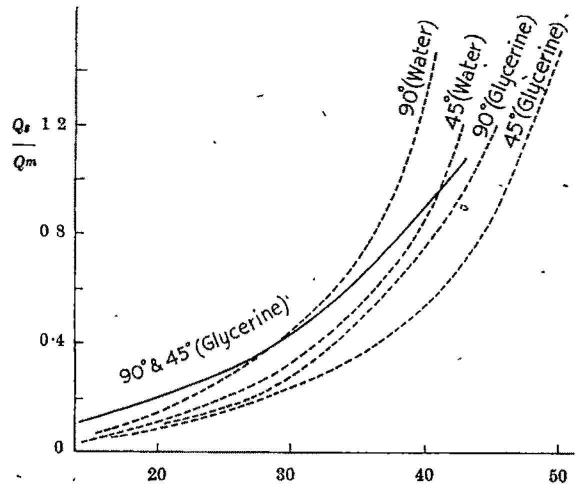

Fig. 2. Critical distance x for wide (——) and narrow (- - - -) branches, different angles and viscosities

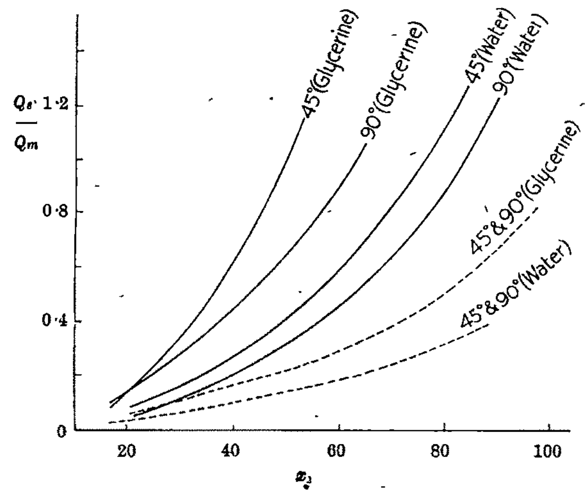

Fig. 3. Limiting distance x_2 for wide (——) and narrow (- - - -) tributaries at angles of 45° and 90° and different viscosities

from the branch will pass into it are greater with increasing viscosity and decreasing width of the branch. The angle of outflow is of little significance when the values of Q_s/Q_m are those likely to occur in the portal venous circulation.

For inflow from a tributary to a straight main tube, the apparatus is shown in Fig. 1*b*. The flow-rates, Q_s of the coloured liquid in the tributary and Q_m in the upper part of the main tube, as well as the distances x_1 and x_2, were measured. With glycerine, x_1 was usually zero unless the ratio Q_s/Q_m was very high: this measure is therefore not discussed here. The value of x_2 was measured about 6 cm. below the junction; here the coloured tributary stream was nearly always flowing parallel to the axis of the main tube. Graphs of Q_s/Q_m against x_2 were drawn, x_2 being expressed as a percentage of the main tube diameter (Fig. 3). In contrast to the findings for outflow, the values of x_2 depended on the total flow-rate Q_t (= $Q_s + Q_m$). However, when Q_t exceeded 100 ml./min., the results were effectively independent of Q_t. This flow corresponds to an average velocity of 2·1 cm./sec. and, since lower velocities would not be physiologically important[3], only the experimental results for the higher values of Q_t are given in the graphs. It was concluded that, for a given value of Q_s/Q_m, the chances of particles from the tributary passing far across the main tube are greatest when the tributary is narrow, the liquid is of low viscosity and (in the case of wide tributaries) when the angle of junction is large.

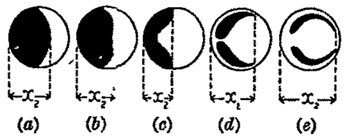

Fig. 4

Finally, we considered major and minor tributaries uniting to form a symmetrically-placed main tube. The apparatus is shown in Fig. 1*c*. The major tributary and the main tube were 10 mm. in diameter; the minor tributary was 8 mm. ('wide') or 4 mm. ('narrow'). The rates of flow in the major and minor tributaries ($Q_{\text{maj.}}$ and $Q_{\text{min.}}$) and the distance x_2 was measured (Fig. 1*c*). The significance of x_2 requires further explanation, since—except at high values of $Q_{\text{min.}}/Q_{\text{maj}}$—the liquid from the minor tributary spread out on entering the main tube. This is shown in the cross-sectional diagrams of Fig. 4 *a* . . . *e*, which correspond in that order to a decreasing series of values of $Q_{\text{min.}}/Q_{\text{maj.}}$. The distance x_2 is thus the limit of penetration across the main tube *as seen in profile*. The lower portions of the curves in Fig. 5, where the slope is negative, correspond to this circumferential spreading, which occurs for most physiologically important values of $Q_{\text{min.}}/Q_{\text{maj.}}$. The total flow-rate Q_t (= $Q_{\text{min.}} + Q_{\text{maj.}}$) is of considerable importance; the effect of altering the total flow, using wide tributaries at 90°, is shown in Fig. 5. A similar effect was observed using narrow tubes or 45° junctions. With water, the circumferential spreading was found to occur at lower values of $Q_{\text{min.}}/Q_{\text{maj}}$ than with glycerine. For a given value of $Q_{\text{min.}}/Q_{\text{maj.}}$, the chances of particles

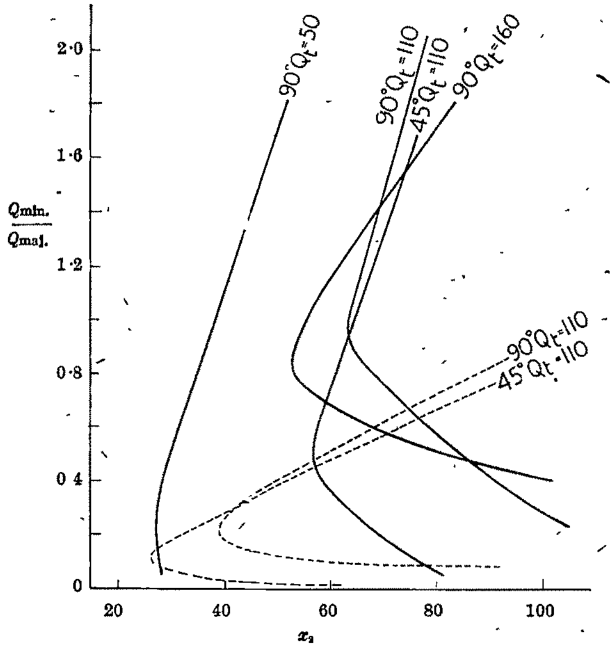

Fig. 5. Penetrating distance x_2 for symmetrically joined major and minor tributaries, using wide (——) and narrow (·······) minor tributaries, differing angles and three rates of total flow (Q_t); glycerine throughout. The curve - - - - is qualitative only

from the minor tributary passing far across the main tube are greater when the angle of junction is large (Fig. 5). In flow conditions simulating those within the portal venous system, the circumferential spreading is especially marked when the diameter of the minor tributary is large, the ratio $Q_{\min}/Q_{\text{maj.}}$ low and the viscosity of the liquid high.

Physical explanations of the experimental curves will be discussed later.

To summarize, it may be said that when the blood-flow within the hepatic portal vein is compared in different species, the following principles should be borne in mind: (1) At the liver hilum the angle of branching of the portal vein is immaterial. For a given ratio of the rates of flow in the main vessel and a branch, a narrow diameter branch is more likely to withdraw particles from far across the main vessel than is a wide one. (2) The manner of formation of the portal vein is important. Where it is formed by a tributary joining a straight main vein, as in Fig. 1b, particles are more likely to pass across the portal vein when the rate of flow in the tributary is large and its diameter small. The converse is true where the portal vein is formed by the symmetrical union of a major and minor tributary, as in Fig. 1c, unless the rate of flow in the minor tributary is very high. In both types of junction more crossing-over of the streams occurs when the angle of union is large than when it is acute.

FINE STRUCTURE OF THE INSECT RETINULA AS REVEALED BY ELECTRON MICROSCOPY

By DR. HUMBERTO FERNÁNDEZ-MORAN

Nerve Ultrastructure Department, Venezuelan Institute for Neurology and Brain Research, Caracas, Venezuela

IN the course of electron microscope studies of the compound eye of insects, interesting structural details of the visual cells forming the retinula have been observed, which bear relation to the complex functional properties of these light receptors.

The percipient portion known as the retinula at the base of each ommatidium consists of a group of generally seven or eight elongated visual cells, arranged so that their differentiated medial borders (rhabdomeres) form together the central rhabdom or optic rod occupying the longitudinal axis of the ommatidium[1] (Fig. 1,*a*). An analysis of the submicroscopic organization of these receptor elements was carried out by electron microscope examination of ultrathin (200 A.) serial sections of whole insect eyes fixed with osmium tetraoxide and embedded in methacrylate. In view of the tough chitin components of the insect eye, a diamond knife[2] had to be used for routine serial sectioning.

In transverse sections through an ommatidium of the eye of the house-fly (*Musca domestica*), the seven rhabdomeres of the corresponding retinula cells appear as dense round or oval bodies, 1–2 microns in diameter, which are grouped in a regular pattern around the light granular central region (Fig. 1,*b*).

Each rhabdomere is surrounded by a double membrane (approximately 200 A. thick), and most of these elements show a characteristic internal laminated structure represented by twenty to thirty transverse dark lines alternating with light spaces, with a regular period of approximately 500 A.

Serial sections indicate that this transverse lamination corresponds to corrugated and perforated membranes running generally parallel to the long axis of the rod-shaped rhabdomere (Fig. 1,*c*). In addition to this predominant type of longitudinally oriented lamination, the other rhabdomeres in each ommatidium exhibit a distinct fenestrated structure (Fig. 1,*d*) formed by a network of intersecting oblique transverse dark lines. This characteristic appearance in cross-sections may correspond to fenestrated disks arranged with their planes perpendicular to the rhabdomere axis (Fig. 2,*c*).

In longitudinal sections through a rhabdom, the two main types of internal structure can be readily recognized in adjacent rhabdomeres (Fig. 2,*a*) separated by the clear central space containing fine filaments and a granular material. The most common texture encountered is represented by a fenestrated membrane with a roughly hexagonal framework of dark lines in which an axial periodicity of approximately 600 A. can be detected (Fig. 2,*b*). This characteristic structure probably corresponds to the longitudinally oriented membranes described in the transverse sections (Fig. 1,*b*).

The second type of structure appears as a system of regular transverse light bands alternating with dark bands (approximately 600–700 A. in thickness), each of which is delimited by two dark, segmented lines (Fig. 2,*c*). These dark bands can be interpreted as representing perforated disks arranged perpendicularly or obliquely to the long axis of the rhabdomere.

Each of the rhabdomeres constituting a rhabdom exhibits a slightly different, characteristic fine structure; but as a group they are nevertheless organized in certain basic patterns. Thus, in transverse sections (Fig. 1,*b*) the six external rhabdomeres symmetrically distributed around the central rhabdomere (*D*) can be grouped into three pairs of elements which are similar in shape, size and internal structure. These paired rhabdomeres are usually located diagonally opposite to each other (Fig. 1,*b*: *A*1, *A*2; *B*1, *B*2; *C*1, *C*2).

The differentiated submicroscopic organization of the rhabdom depicted on the basis of these preliminary findings suggests a correlation with the functional differentiation of the retinula cells which has been postulated in order to account for the remarkable capacity of insects to discern the plane of polarized light and to orientate themselves by it[3]. According to the investigations of Autrum[4], the visual cells of each ommatidium may perform the functions of radially placed analysers for polarized light. The highly regular submicroscopic laminated structure of the single rhabdomeres described here might well furnish the structural basis for the optical properties (such as textural birefringence of the composite laminated and fenestrated bodies, combined with the intrinsic birefringence of its components) which are required of such an analyser for polarized light.

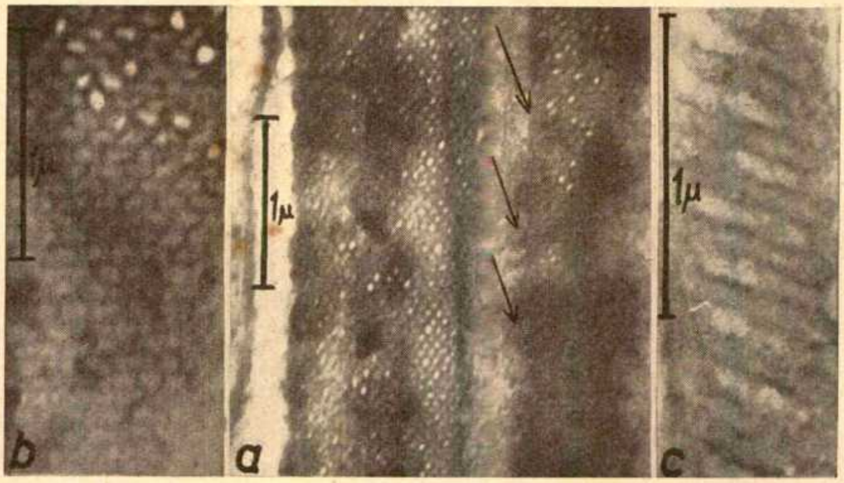

Fig. 2. Electron micrographs of longitudinal sections of rhabdomeres. (*a*) Longitudinal ultrathin section of two rhabdomeres of the house-fly eye with fenestrated structure and transverse lamination (arrows). × 22,000. (*b*) Longitudinal section of a rhabdomere showing the regular fenestrated framework of the membrane. × 29,000. (*c*) Longitudinal section of a rhabdomere with transverse laminated structure. × 39,000

Moreover, the characteristic distribution pattern of the rhabdomere pairs would provide a spatial arrangement adequate for the proposed functions of a compound analyser ascribed to an ommatidium.

The same general type of fine structure has been observed in the rhabdomeres of all other insects examined so far (the honey bee, *Apis mellifiora*, *Erebus* and other tropical Lepidoptera and Odonata). The transverse laminated structure of the receptors in the visual cells of insects described here is similar in some respects to the submicroscopic disks found in the external segments of the rods and cones of the vertebrate retina[5]. Further details of the rhabdomere texture and of their association with specialized submicroscopic tubules, as well as their characteristic structural relationship with the components of the optic ganglion, will be published elsewhere. Atomic and Astronomical Time

A cæsium atomic resonator[1] has been in operation as the standard of frequency at the National Physical Laboratory for eight months and its performance under a variety of conditions has been investigated. It has been found that the electrical and mechanical conditions required for an accuracy of repetition of ± 5 parts in 10^{10} are easily attained, and it is expected that the model now being designed for routine operation will give an accuracy approaching ± 1 part in 10^{10}.

During this investigation many changes were made to the cæsium beam chamber; but it was nevertheless found possible to calibrate the quartz standard under specified conditions at regular intervals of about one week. The results of the calibration, given in Fig. 1*a*, are based on the value of the cæsium frequency determined in June 1955[1]. The actual values are not therefore of particular interest, and it is only the variations with which we are here concerned. The National Physical Laboratory quartz clock *Q*13 was chosen for these measurements, because it had been in operation for three years with a uniform rate of change of frequency of 3·5 parts in 10^9 per month and appeared, therefore, to be one of the most stable of existing timekeepers. It is seen that for a further period of six months the rate of change was almost constant at the same value, but that it then changed to 1·5 parts in 10^9 per month. No reason for this change could be found.

The determination of the rate of the clock in terms of astronomical time is somewhat complicated[2]. For its time determinations, the Royal Greenwich Observatory is able to use all the most reliable clocks in Britain by means of a continuous interchange of information between the different laboratories, and *Q*13 is one of the clocks used in this way. Details of its calibration in astronomical time could therefore be supplied by the Observatory, and it was not necessary to wait for the publication of time signal corrections, as would normally be necessary for precise measurements. The results obtained with the different clocks are combined to give a mean clock, the rate of which is determined by observing the times of star transits. This mean clock can then be used to give the performance of the individual clocks. The values for *Q*13 supplied by the Observatory one month in arrears are given in Fig. 1*b*. The curve of Fig. 1*c* is obtained by subtracting the ordinates of Fig. 1*b* from those of Fig. 1*a*, and it thus represents the variations of the unit of astronomical time in terms of the cæsium standard. The maximum variations of ± 4 parts in 10^9 agree well with the estimate of the accuracy of the Observatory time service made by Smith[3].

It is customary for the Observatory to make a new assessment of the unit of time after a period of six months, when the clock performances and the stellar observations can be viewed in retrospect. This has not yet been done for the period in question; but a special reassessment was made at the end of January, using the results obtained over a long period with a group of nine quartz clocks. The results given in Fig. 1*d* show a considerable improvement in uniformity. This uniformity is mainly a function of the clock performance, only the general slope of the line being determined by the astronomical measurements. Finally, in Fig. 1*e* are plotted the monthly means of the star observations in terms of the cæsium standard (Smith, H. M., and Tucker, R. H., private communication). The results give an indication of the variation in the rate of rotation of the earth, although the scatter of the points about a mean curve is probably due to the instrumental errors associated with the astronomical observations.

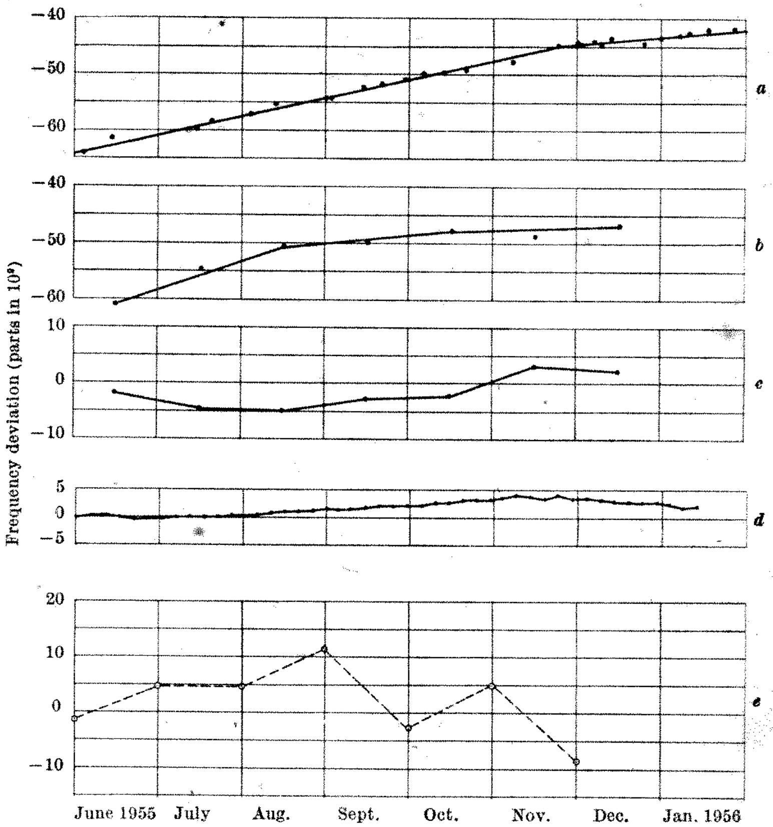

Fig. 1*a*. Frequency deviation of *Q*13 in terms of the cæsium 3·0–4·0 resonance, based on the frequency of the cæsium resonance measured in terms of the Royal Greenwich Observatory monthly current value of *Q*13 in June 1955.

Fig. 1*b*. Frequency deviation of *Q*13 in terms of the Royal Greenwich Observatory monthly revised values.

Fig. 1*c*. Royal Greenwich Observatory monthly revised values in terms of cæsium.

Fig. 1*d*. Royal Greenwich Observatory reassessed values, based on astronomical observations and the mean of nine quartz clocks, in terms of cæsium.

Fig. 1*e*. Astronomical observations in terms of cæsium.

A mean curve would agree fairly well with the periodic variation predicted from the observations of previous years.

Another important result of the investigation was the gradual realization that when the most suitable conditions of operation had been found, and the novel techniques mastered, the cæsium resonator became a remarkably simple instrument to use. There can be no doubt that this or some other atomic standard will revolutionize the technique of determining the unit of time, and will in practice be used to make the unit available, however it may be defined.

We are glad to acknowledge the co-operation of Mr. H. M. Smith and Mr. R. H. Tucker of the Royal Greenwich Observatory in supplying the astronomical data.

Gelatin Light-scattering, by a New Enzymic Digestion Technique

In applying light-scattering techniques to molecular-weight and dissymmetry measurements for gelatin fractions in solution, serious doubts arose concerning the efficiency of the usual clarification methods (ultrafiltration, high-speed centrifugation). A convincing check of clarifying processes existed only for fractions of low molecular weight, where the experimental value of the dissymmetry, Z, should approximate to the theoretical value, unity, if all suspended impurities have been removed. For higher molecular weights, a solution free from impurities would be expected to give Z greater than 1, and the procedure adopted by other workers has been to repeat the clarification until Z became constant. It was suspected that this limit did not correspond with complete clarification, and that the use of this criterion caused significant errors in the 90° scatter (and M_w) and large errors in the values of Z.

The alternative, and novel, procedure was therefore adopted of measuring the light scattered from a solution which had been given only a moderately effective clarification, and then destroying the gelatin macromolecules by adding a solution of Armour crystalline trypsin. The residual scatter was mainly that of the solvent and the impurities, since the digestion products of the gelatin, and the added trypsin, have negligible scatter. Subtraction of the residual scatter from the original figures then gives the scatter due to gelatin alone, so that the molecular weight and true dissymmetry of the dissolved gelatin may be obtained. The effects of the addition of trypsin may be seen in Table 1.

In this experiment the gelatin solution was forced by air pressure (2 lb./sq. in.) through a '5 on 3' sintered glass disk into the metal semi-octagonal cell (capacity 50 ml.), held at 40·0° C. At the time '0·50 hr.', 2 ml. of the trypsin solution (concentration 10 mgm. per 100 ml. water) was pipetted into the cell. The trypsin solution had also been filtered through a '5 on 3' sintered glass disk. After 24 hr. a further 2 ml. of the trypsin solution was added, and the scatter increased by 2 per cent at each angle.

Table 1

Time (hr.)	Scatter (arbitrary units) at 135°	90°	45°	Apparent dissymmetry ($\lambda = 546$ mμ)
0	26·0	12·0	32·0	1·23
0·50	26·0	12·0	32·0	1·23
0·75	9·5	4·65	14·7	1·55
1·0	8·55	4·4	13·6	1·59
2·0	8·0	4·1	13·8	1·73
4·0	8·0	4·1	13·9	1·74
24·0	8·0	4·1	13·9	1·74

Gelatin concentration: 3·35 gm. per litre, in 0·5 molar saline, pH 6·8

These results show that the gelatin fraction contributed only two-thirds of the original 90° scatter, and gave unit dissymmetry of scatter, within experimental error. From the 90°-scatter due to gelatin a value of 22,000 was deduced for M_w.

In low-angle studies the extra accuracy available through the trypsin digestion technique is incompletely realized unless the solutions are clarified as effectively as possible. On the other hand, in the determination of molecular weight by the 90°-scatter method, where the suspended impurities contribute a smaller proportion of the total scatter, poor clarification may be adequate. For example, a 0·5 M saline neutral solution of another gelatin fraction was divided into two parts, and one part was filtered as in the above experiment whereas the other was filtered, under gravity, through a coarser sintered glass disk only. The following results were obtained:

	Type of filter 2	'5 on 3'
Molecular weight gelatin	119,000	115,000
Percentage original 90°-scatter due to gelatin	64	98

In principle, the method is applicable to many macromolecular systems, and may be found to be particularly useful for aqueous solutions, many of which are more difficult to clarify than non-aqueous solutions. The successful application of the technique rests principally upon selective breakdown of the macromolecules under investigation, and it is in this connexion that enzymic attack can be so valuable. It is also necessary that the mode of degradation should interfere as little as possible with the scattering from the solution, and that the impurities should not settle out of solution during the experiment. As the above experiments confirm, the gelatin/trypsin system meets these requirements.

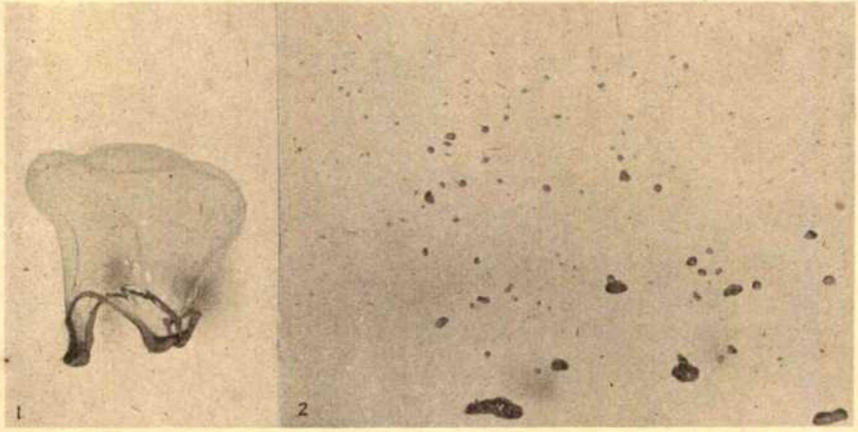
Shattering of Large Drops

The purpose of this communication is to present some experimental results obtained during a laboratory investigation of the mechanism of the break-up of drops. Results of previous workers indicate that drop deformation and turbulent air flow are major factors in the break-up of drops suspended in the air stream of vertical wind tunnels. Shattering break-ups have been observed for drops 5–9 mm. in diameter as a result of sudden changes in the velocity of the wind stream, or as a result of collisions between drops[1]. The fragments from the disintegrations of one hundred parent drops between 9 and 12 mm. in diameter have been collected and a size distribution determined[2]. No account of the actual mechanism of break has come to our notice, although factors responsible for the deformation of drops between 5 and 7 mm. in diameter have been evaluated[3].

We now report a phenomenon associated with the shattering of large drops that apparently has escaped the attention of previous workers in the field. Reasonably well-formed drops, 10–25 mm. in diameter, were allowed to fall through stagnant air and the resulting break-ups observed. Most drops larger than 10 mm. in diameter and all drops larger than 12 mm. in diameter were shattered with considerable violence after a limiting velocity had been reached. High-speed photographic techniques were employed in the study of the actual break-ups, and hundreds of photographs were obtained showing their different phases.



(1) Inflated drop in which the canopy has been torn by aerodynamic forces. (2) Fragments from the break-up of a drop 15 mm. in diameter

Photographic evidence indicates that deviation from sphericity increases with increasing velocity of the drop as it falls through the air. Smaller drops assume a reasonably stable shape at terminal velocity; but larger drops are deformed to such a degree before the terminal velocity is reached that a critical value for the ratio of the minor to the major axis is attained. When this ratio is reached, the centre of the flattened drop suddenly bulges upward and the drop opens in somewhat the same manner of a parachute. Aerodynamic forces immediately rupture the canopy of the inflated drop, which disintegrates into a shower of smaller droplets. From the time the first bulge appears on the upper surface of the parent drop until the break-up is complete, less than one-fifteenth of a second elapses. Fig. 1 shows a typical drop in the stage of disintegration in which the canopy has just been torn by aerodynamic forces. The size distribution of fragments to be expected from the break-up of a 15-mm. drop is indicated in Fig. 2.

We wish to thank the Nova Scotia Research Foundation for the support given this project. Further details of the work and techniques of large-drop formation will be published elsewhere.

Solvent Extraction of Polonium from Nitric Acid Solutions

THE usual valency of polonium is 4, as was established by tracer-scale investigations[1] and by recent studies[2] with milligram amounts of the element. It has also been suggested[3], from electrochemical deposition experiments and co-precipitation studies, that hydrazine, hydroxylamine, sulphur dioxide, oxalic acid and hydrogen peroxide can, in certain conditions, reduce tracer-amounts of polonium to a lower valency state, the reduction occurring readily.

Recent investigations[2] with weighable quantities of material have shown that quadrivalent polonium is reduced, in halogen acid solution, by sulphur dioxide and hydrazine to a bivalent state, with some evidence for an intermediate trivalent state in the case of the chlorides. It was found that hydroxylamine and oxalic acid have no effect on solutions of polonium chlorides, and that hydrogen peroxide oxidizes macro-amounts of bivalent polonium to the quadrivalent state.

Investigating the extraction of trace amounts of polonium from nitric acid solutions by diethyl ether and other organic solvents we found an interesting property, probably related to a lower-valency state of this element.

Some microcuries of pure polonium, prepared by anodic electrodeposition[1], were dissolved in nitric acid with a molarity ranging from 1·75 to 8. Negligible extraction was found by shaking these solutions with the same volume of peroxide-free diethyl ether, in the absence of daylight. However, when ether containing peroxide was used, a part of the polonium passes into the organic phase. The polonium was found to be extracted by peroxide-free diethyl ether when some drops of hydrogen peroxide or some milligrams of hydrazine or hydroxylamine were previously added to the nitric acid solution; with oxalic acid no extraction was observed.

When sulphur dioxide was bubbled through concentrated nitric acid solutions of polonium visible decomposition was observed, and the polonium was not extracted from these solutions by peroxide-free ether. Extraction occurs when the nitric acid molarity is adjusted after previous reduction of polonium by sulphur dioxide in dilute nitric or hydrochloric acid. Fig. 1 illustrates the effect of increasing nitric acid molarity on the percentage of polonium extracted, for the various reducing agents used.

It can be seen from the graph that approximately the same percentage of polonium is extracted, at a given nitric acid molarity, by peroxide-containing ether and also by peroxide-free ether when to the aqueous phase hydrogen peroxide or sulphur dioxide is added. However, the results with sulphur dioxide are less reproducible at high nitric acid molarities, which is probably due to the oxidation of this reagent by nitric acid. The percentages of polonium extracted are approximately the same as those obtained in the extraction of uranyl nitrate from nitric acid solutions

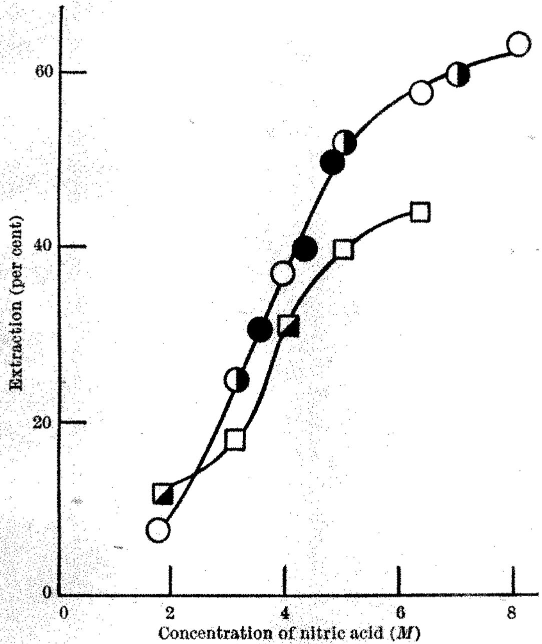

Fig. 1. ●, Sulphur dioxide ; ◐, hydrogen peroxide ; □, hydrazine ; ◪, hydroxylamine ; ○, organic peroxide

by diethyl ether ; nearly 65 per cent of polonium is extracted from a solution in 8 M nitric acid by ether containing peroxide.

The same amount of polonium is extracted by peroxide-free ether when the nitric acid solution contains hydrazine or hydroxylamine ; the percentages of extraction are lower than those obtained with ether containing peroxide or with the other reagents. Visible decomposition of the solution was observed at nitric acid concentrations greater than 7 M, and no extraction was possible from these solutions.

No extraction occurs if instead of these reducing agents a strong oxidant such as chromic acid is added to the nitric acid solution containing the radioelement. Complexing agents of polonium such as hydrochloric acid lower the distribution coefficient, and no salting-out effect was found by adding ammonium nitrate to the nitric acid solutions. Back-extraction was readily verified when the organic phase with the extracted polonium is shaken with water.

In the presence of the same reducing agents other organic solvents such as di*iso*propyl ether and *iso*amyl alcohol also extract polonium from concentrated nitric acid solutions, although to a smaller extent than diethyl ether. However, it was found that with n-amyl alcohol and methyl*iso*butyl ketone the extraction occurs even when no reagent is added to the nitric acid solution ; but the presence of reducing agents in these solvents was verified. On the contrary, oxygen-free solvents such as carbon tetrachloride or chloroform fail to extract the radioelement in any conditions.

In agreement with the previous work on the tracer-scale, the solvent extraction behaviour of tracer-amounts of polonium suggests that hydrogen peroxide and hydroxylamine act as reducing agents in the conditions described. The reduction of trace-amounts of polonium by hydroxylamine has been reported before[3b] in acetic and sulphuric acid media, on warming the solutions. It is interesting to observe that for plutonium also the oxidation-reduction behaviour of trace amounts with hydrogen peroxide, in nitric acid solution and other media, differs from that with macro-concentrations of the element[4]. In the trace-experiments quadrivalent plutonium appears to be oxidized to quinquivalent plutonium or to sexavalent plutonium, whereas in the macro-experiments reduction to trivalent plutonium was observed.

It has been shown[5] that only a limited number of elements that have a marked tendency to form nitrate complexes are extracted in relatively high proportion from nitric acid solutions by diethyl ether. Investigating the anion-exchange behaviour of polonium in the presence of reducing agents, we have found evidence for negatively charged complexes in nitric acid media (unpublished results).

We are indebted to Prof. Fritz Feigl and to Dr. K. W. Bagnall for helpful discussions.

Chromatographic and Spectroscopic Properties of Ellagic Acid, and its Occurrence in Dicotyledonous Plants

CHROMATOGRAPHIC and spectrophotometric properties of ellagic acid have now been investigated in order to facilitate the identification of this acid in plant extracts and hydrolysates. In early studies, ellagic acid has not always been adequately characterized; but the present work has confirmed the occurrence of this substance in a wide range of dicotyledonous plants[1]. Ellagic acid has also been identified in *Terminalia arjuna, bellirica, citrina, pallida* and *travencorensis* for the first time.

Table 1. R_F VALUES

Compounds	Ellagic acid	Flavellagic acid
Aqueous 40 per cent (v/v) formamide, pH 3·5	0·33	0·12
60 per cent formamide, pH 3·5	0·61	0·27

In order that paper chromatography may be used for the unequivocal identification of ellagic acid, solvent systems must be selected in which this substance has a reasonably high mobility. It has now been found that formamide – water mixture, buffered at pH 3·5 with formic acid, separates ellagic and flavellagic acids (Table 1). Ellagic acid has a high R_F value (0·70)[2] in benzyl alcohol–*tert.*-butanol–*iso*-propanol–water (3 : 1 : 1 : 1) mixture containing 1·8 per cent formic acid, and this solvent system has also been found useful for chromatographic identification purposes.

A study of the absorption spectra of ellagic and flavellagic acids (Table 2) has now shown them to

Table 2. ABSORPTION SPECTRA (MAXIMA, IN mμ, FOLLOWED BY LOG ε) IN β-METHOXYETHANOL

Ellagic acid	256 (4·53) ;	279 (4·63) ;	357 (4·15)
Flavellagic acid	266 (4·58) ;	279 (4·51) ;	358 (4·14)

Table 3. INFRA-RED MEASUREMENTS (BANDS. IN CM.$^{-1}$, FOLLOWED BY THE GROUP CONCERNED) IN 'NUJOL' MULLS AND POTASSIUM BROMIDE DISKS

Ellagic acid	Flavellagic acid	
1,712	1,712	; carboxyl stretching vibration
1,600, 1,580, 1,518	1,600, 1,580, 1,518	; aromatic bands
3,200	3,200	; H-bonded hydroxyl
3,570, 3,485	3,445	; free hydroxyl

belong to the type characteristic for compounds in which the phenolic hydroxyls are conjugated through the aromatic nucleus with carbonyl functions. Infra-red measurements (Table 3) have now shown a fundamental carbon–oxygen stretching vibration at 1,712 cm.$^{-1}$, which is assigned to the lactonic carboxyls. The comparatively low frequency of the lactonic carboxyl band is due to the lack of strain in six-membered lactone rings[3], and also to the fact that the lactonic carboxyls are attached to aromatic rings. It is well known[4] that the frequency of carboxyl functions is less when measured in the solid state than in solution. Both substances have bands assignable to H-bonded and to free hydroxyl, the band at 3,445 and 3,485 cm.$^{-1}$ respectively in the two substances being too strong to be assigned to the overtone of a ketonic carbon–oxygen stretching vibration. All attempts to prepare ketonic derivatives of ellagic acid have failed. In the solid state and in neutral and acidic solution, ellagic acid behaves in agreement with the conventional configuration, and it lacks unusual ketonic properties.

Our electrometric titration of ellagic acid shows that dissolution in cold alkali is not accompanied by ring-fission, and this is of interest in connexion with the recent isolation[5] from alkaline medium of a quinonoid benzylation product, $C_{42}H_{30}O_8$, by a reaction clearly involving enolic-benzylation of the lactone carbonyls. In alkaline solution, ellagic acid reacts in this case in the tautomeric quinonoid form, previously suggested in an entirely different context by Perkin[6].

Resonance energy is associated with the condensed ring-structure for ellagic acid, and it is accordingly suggested that the correspondingly low redox potential explains the poor response which the substance gives with the ferric chloride – ferricyanide reagent for polyphenols.

Some aspects of ellagic acid chemistry are now being studied in these laboratories, and detailed results will in due course be communicated elsewhere.

I thank Dr. H. Phillips, director of the British Leather Manufacturers' Research Association, for his interest and encouragement, and the Council of the Association for permission to publish this communication. Discoloration of Muscle Preparations from Codling (*Gadus callarius*) by Degradation Products of I-Methylhistidine

BROWN discolorations of foodstuffs, resulting from Maillard-type reactions between amino-compounds and sugars, have been known for many years. Recently, it has been established that in the whole muscle of fish and the separated muscle extractives, reactions between amino-compounds and ribose may take place very readily: the free glucose in the muscle is less reactive[1,2]. However, evidence has been accumulating in this laboratory that such reactions may not contribute all the discoloration found in the muscle of codling under certain processing conditions.

Freeze-dried preparations of muscle extractives showed relative humidity/'browning' relations atypical of Maillard reactions[3], and considerable quantities of free sugars have been detected in badly 'browned' samples of stored vacuum contact-plate-dried muscle kindly given by Mr. E. J. Rolfe. High sugar values have also been found in 'browned' samples of freeze-dried muscle prepared by Dr. A. C. Jason, Dr. R. M. Love and me at this Station and afterwards stored over phosphorus pentoxide at room temperatures (~ 15° C.) in daylight (conditions which would largely eliminate Maillard reactions). In darkness, little or no 'browning' was observed under these zero-humidity conditions. Maillard-reactive free amino-nitrogen was in very large excess over sugar in all these preparations[2,4].

In investigations into the enzymic hydrolysis of anserine (β-alanyl-1-methylhistidine) in the muscle of codling, it was reported that synthetic *dl*-1-methylhistidine was unstable and developed discoloration in light[5]. As the natural amino-acid is liberated rapidly in the muscle after death (to some 60–80 mgm. after 8–10 days storage in ice at an ambient temperature of 2° C.[4]), it was thought that 1-methylhistidine degradation could contribute appreciably to any discoloration taking place during processing and storage of dehydrated fillets. For the present study, *dl*-1-methylhistidine has been prepared by the hydrolysis of anserine-containing fractions from pike (*Esox lucius*)[5] and fractionating the hydrolysate by displacement from 'Dowex 2 (OH)' resin columns with $N/50$ hydrochloric acid. The anhydrous amino-acid was repeatedly crystallized from 80 per cent ethanol.

The extractable free amino-acids and sugars of the muscle of 18–24 in. codling were removed from structural material by exhaustively dialysing homogenates against distilled water. Aliquots of extractive-free suspension, together with *dl*-1-methylhistidine at a concentration equivalent to 50 mgm. per 100 gm. wet weight original muscle, were freeze-dried over phosphorus pentoxide. They contained 0·3–0·4 per cent 'water' as estimated by 4-hr. heating to constant weight in a forced-draught oven at 105° C. Stored in desiccators over phosphorus pentoxide in daylight at 15° C., the preparations changed rapidly from white to yellow-brown at the surface. Controls with no 1-methylhistidine remained white, as did preparations containing the amino-acid if they were stored in darkness.

When freeze-dried suspensions containing 1-methylhistidine were equilibrated and stored at different relative humidities, it was found that, in preparations at high humidities (60–100 per cent relative humidity), a yellow-brown coloration appeared throughout:

this coloration did not occur in the absence of the amino-acid and was noticeable at relative humidities as low as 30 per cent. 'Browning' increased rapidly with temperature. During these experiments, controls with no added amino-acid have been checked chromatographically for the appearance of sugar from non-dialysable bound forms, and this has not been found. Under these conditions, it is possible that metallic ions bound to protein in a non-dialysable manner could be available to catalyse the degradation.

In relation to this work, it is of interest that 4 (5)-methylimidazole has been isolated from mixtures from Maillard-type browning reactions between glucose and ammonia[6] and glucose and glycine[7], so that there is evidence that simple imidazole compounds may lie on one of the pathways of such reactions. In physico-chemical studies on histidine, Lewin[8] has demonstrated degradations leading to the formation of yellow coloration in solution, and that glucose may inhibit this action under certain conditions.

The present communication indicates that simple compounds of imidazole type may initiate a non-enzymic discoloration of foodstuffs in the effective absence of sugar. It is not suggested that, in the presence of sugar and free amino-compounds under Maillard-reactive conditions, it is likely to be a major factor in 'browning'. Admixture of *dl*-1-methylhistidine and *d*-ribose under such conditions gave a dark-brown coloration considerably in excess of the yellow-brown obtainable with the amino-acid alone.

The chromatographic separations of anserine and *dl*-1-methylhistidine were carried out in part by Mr. J. Murray. The work described in this communication is part of the programme of the Food Investigation Organization of the Department of Scientific and Industrial Research.

Experimental Allergic Encephalomyelitis produced by Tubercle Bacillus Residues

It has been known for some time[1] that mixtures of acid-fast bacilli and homologous brain in water-in-oil emulsions produce allergic encephalomyelitis when injected parenterally into animals. A knowledge of the chemical composition of the substances responsible for producing this reaction is important, because of the light it might throw on processes occurring in some human and animal demyelinating diseases. Much attention has been devoted to the chemistry of the brain factor[2]; but relatively little is known concerning the bacillary factor. The latter was considered by Allegranza and Rovescalli[3] to be a high molecular-weight complex consisting largely of protein with the lipopolysaccharide acting synergistically. Working independently and along similar lines, we reported[4] that residues left after fat extraction of human tubercle bacilli retained encephalitogenic activity, whereas the material extracted was inactive; the activity was relatively resistant to acid, alkali or proteolytic enzymes, and was present only in the insoluble residues. It has now been found that, when tubercle bacilli are treated serially with these reagents, the insoluble residue is still active.

The starting material, obtained from Glaxo Laboratories, Ltd., was heat-killed human tubercle bacilli, which had been extracted with acetone and *iso*propyl ether[4]. A sample (10 gm.) was treated successively with $N/2$ potassium hydroxide for 48 hr. at 0–4°, N hydrochloric acid for 24 hr. at room temperature, pepsin (B.D.H., 200 mgm.) in $N/10$ hydrochloric acid for 24 hr. at 37° (two digestions), trypsin (B.D.H., 200 mgm.) in $M/10$ sodium bicarbonate for 24 hr. at 37° (two digestions). The dried residue, which after these treatments weighed 2·8 gm., was then extracted (Soxhlet) for four days with each of the following solvents to remove any free lipid: *n*-butanol, benzene and finally chloroform–methanol (2 : 1, v/v). Most of the lipid was extracted by the first solvent, and by the end of each four-day period no further material was being extracted. The resulting residue, on drying, weighed 1·9 gm. and was a pale yellow powder, no longer acid-fast by the Ziehl–Neelsen staining technique.

The residue was tested, as described by Colover[4]; it was incorporated (0·5 mgm./ml.) in an emulsion containing 'Bayol F' (Esso Standard Oil Co., N.J.), 'Falba' (Pfaltz and Bauer, Inc., N.Y.) and homologous brain suspension and the mixture injected intramuscularly into a group of six guinea pigs. Four injections of 1 ml. each were given at weekly intervals to each animal. On the thirty-first day the three survivors were killed. One animal was killed on the twenty-eighth day because it had become moribund; two others died a few days before the thirty-first day and had become paraplegic. On histological examination, the three animals which had shown clinical signs and one which had not were found to have the typical lesions of experimental allergic encephalomyelitis, as illustrated in Fig. 1. Histologically, two showed some evidence of perivascular demyelination in addition to the characteristic cellular reactions, but the amount of demyelination was somewhat less than that produced by the original starting material.

The analysis of the residue is given in Table 1. The percentage figures are based on dry weight. Carbohydrate was determined in the supernatant

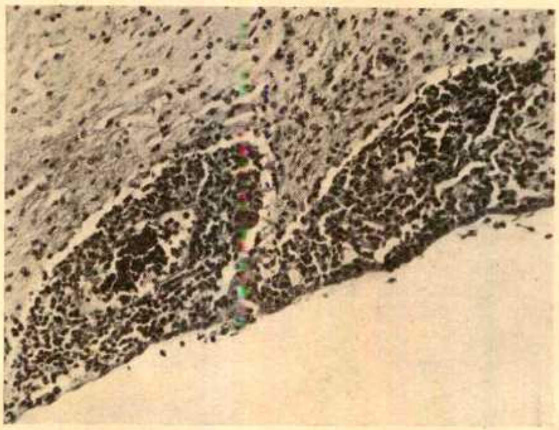

Fig. 1. Cross-section of guinea pig brain showing intense inflammatory-cell infiltration in the neighbourhood of two sub-ependymal venules (hæmatoxylin and eosin. × 210)

Table 1. ANALYSIS OF ACTIVE RESIDUE

Nitrogen	11·9 per cent
Hexosamine (ref. 5)	1·0 ,, ,,
Carbohydrate (as galactose-mannose) (ref. 6)	12·7 ,, ,,
Mycolic acid	9·8 ,, ,,
Amino-acids (liberated by 6 *N* hydrochloric acid)	Alanine (strong), glutamic acid (strong), diaminopimelic acid (moderate). Others, relatively weak or moderate
Sugars (liberated by *N* sulphuric acid) (ref. 7)	Glucose, galactose (both weak)

after hydrolysis with *N* sulphuric acid. Mycolic acid was determined by isolation following hydrolysis of a weighed sample with 6 *N* hydrochloric acid at 105–110°. The black residue was extracted with hot *n*-butanol. On cooling, the precipitate was collected and weighed. (A further small quantity was obtained from the mother liquor.) The crude substance was acid-fast; its melting point was 53–57°, undepressed by admixture with an authentic sample of mycolic acid supplied by Dr. N. Polgar. The equivalent was about 1,100 (alkali titration) and it contained C, 79·6; H, 12·5 per cent (α-mycolic acid, $C_{88}H_{176}O_4$ requires C, 81·4; H, 13·7 per cent and equivalent, 1,296). The total lipid, which was extracted by chloroform from another hydrolysed sample, was close in amount to the mycolic acid content, and did not appear to contain any other fatty acids in appreciable quantity.

Hydrolysed samples of the residue were examined for amino-acids and sugars by paper chromatography and paper electrophoresis[6]. The amounts of sugars observed were much smaller than expected from the apparent carbohydrate figure in Table 1. Because of this and also because much of the original carbohydrate of the starting material would have been removed by the various treatments, this figure is probably too high.

Since the tubercle lipopolysaccharide, 'wax D'[8], contains similar components to those in the active residue, it was decided to test this substance and also a sample of methyl mycolate, strain Marmorek (melting point 39°) (both supplied by Dr. E. Lederer), for activity as described above and at a dosage of 0·5 mgm./ml. Both substances were found to be inactive. On the other hand, Waksman and Adams[9] found that lipopolysaccharide and wax from tubercle bacilli were active in the production of experimental allergic encephalomyelitis in rabbits. However, these substances were much less active than the intact bacilli, and may not have been entirely free from tuberculoprotein. Several attempts by ourselves and others[3] with wax preparations have failed to produce positive results in guinea pigs. So far as our observations are concerned, the active principle in the tubercle bacillus is a relatively stable and insoluble substance. Although no attempt has yet been made to assess quantitatively the amount of activity of the residue as compared with that of the starting material[4], it is significant that even after a loss of more than 80 per cent as a result of the various treatments, the residue was still active at the same level (0·5 mgm./ml.). This residue is largely protein in character, with glutamic acid and alanine as predominant amino-acids. It would also appear that the mycolic acid present is chemically bound to protein, which would accord with its insolubility and resistance to chemical attack. It is conceivable that this type of substance, which may also contain some polysaccharide, is responsible for the encephalitogenic activity.

We thank Sir Robert Robinson and Drs. N. Polgar, E. Lederer and J. Ungar for helpful advice and material. One of us (J. C.) is in receipt of a grant from the Medical Research Council.

Effect of Vitamin B_{12} Deficiency on Liver Dehydrogenase Activity in Rats

WEANLING rats born of mothers maintained on a diet deficient in vitamin B_{12} during pregnancy were fed on a vitamin B_{12}-free ration for twelve weeks and their liver dehydrogenase levels were compared with those of similar animals receiving 2-μgm. supplements of vitamin B_{12} daily. The basal diet had the composition: whole soya bean flour, 25; groundnut cake flour, 14; sesame cake flour, 14; wheat flour, 14; rice flour, 14; Bengal gram flour, 14; vitaminized starch, 2 (containing adequate quantities of all B-complex vitamins except vitamin B_{12}); shark liver oil, 2; Osborne and Mendel salt mixture, 1. At the end of the experiment, the animals were killed and the excised livers freed of blood clots and immediately chilled and used for measurement of dehydrogenase activities. Liver homogenates prepared in ice-cold *M*/15 phosphate buffer of *p*H 7·2 were used for the measurement of lactic, glutamic, succinic, butyric and choline dehydrogenase activities, according to the method described by Sreenivasa Murthy and Swaminathan[1], using tetrazolium bromide as the hydrogen acceptor. Portions of the liver tissue were used for nitrogen estimation by the Kjeldahl method. The vitamin B_{12} content of the liver was measured microbiologically using *L. leichmannii*-4797 as the test organism.

In a second series of experiments, the effect of vitamin B_{12} injection to deficient rats on the regeneration of liver dehydrogenases was studied. The levels of dehydrogenases in these animals were compared with those found in positive control groups that had been receiving the vitamin supplements since the beginning of the experiment.

The results for dehydrogenase-levels of animals on the diet deficient in vitamin B_{12} and control animals are presented in Table 1. They show a significant difference in weight between the vitamin B_{12}-deficient and control animals, although there was no difference between the two groups with respect to the weight of the liver or the nitrogen content of the liver. The general level of various dehydrogenases in the liver is, however, reduced. The differences in enzyme activity between deficient and control groups are statistically significant. The fact that the pattern

* Standard error of the mean. Figures in parenthesis represent the number of animals.

of change in the deficient animals is always a lowering in all the enzymes studied would indicate that the action of vitamin B_{12} is probably a general one of promoting the synthesis of enzymic protein rather than as a coenzyme factor for the enzymes studied. This is substantiated by *in vitro* studies, where the addition of vitamin B_{12} to the liver homogenates failed to raise the enzyme activities to the same level as those of the vitamin B_{12}-fed controls.

The results of studies on the rate of enzyme regeneration when vitamin B_{12} was injected into deficient animals as obtained in the second series of experiments have been somewhat inconclusive and have not been reported here. A statistical interpretation of the data was not possible owing to the large individual variations and the small number of animals used (four for each group). These experiments are therefore being repeated on a larger number of vitamin B_{12}-deficient animals.

We are indebted to Dr. V. Subrahmanyan, director of this Institute, for his interest in this investigation.

Fæcal Micro-organisms of Parabiotic Rats

SURGICAL techniques for the production of artificial Siamese twins ('parabiotics') are well established for small laboratory animals, and, in skilled hands, provide an elegant method for study of hormone circulation and other problems involving humoral transmission. There is some doubt as to whether capillary anastomosis or the lymphatic system is the primary mode of transfer from one twin to the other; but, in either case, it would seem that parabiotic animals are excellent material for nutritional research. In this connexion, it may be of interest to record that a pair of rats joined in this way since shortly after weaning were among a number of animals studied during a preliminary investigation of the influence of age and diet on intestinal micro-organisms.

The animals, both females, were just under eighteen months old (510 days). Shortly after weaning, they had been joined by the method of Bunster and Meyer[1] and formed part of an extensive programme of work with parabiotics of different ages being carried out at Cornell University by Prof. C. M. McCay and Dr. F. Pope[2]. The rats were receiving the same diet ('stock' + 10 per cent cooked egg) and their management was, of course, identical. It might be expected, therefore, that the various micro-organisms of their alimentary tract would be present in approximately equivalent numbers—assuming diet and intestinal environment to have some influence.

Errors in this type of work are known to be enormous; but the results of 'presumptive' counts from fæcal suspensions made on several days with each of the two rats were fairly consistent, and there was a relatively constant ratio between the numbers of the various organisms from one twin and those from the other, that is, the fæcal flora of the two halves was different. The individuality of each rat was therefore evident.

A pair of rats of comparable age (13 and 14 months), and on a comparable diet, were examined by the same method some time later (in Britain) and roughly the same degree of individuality as reflected in fæcal flora was found. These figures and those from the Cornell parabiotics are shown in Table 1.

Table 1. NUMBER OF ORGANISMS PER GM. OF FRESH FÆCES

m, million; *L*, left; *R*, right.

General numbers. Determined by the most probable number method in the reinforced *Clostridium* medium of Hirsch and Grinsted (ref. 3) incubated at 37° C. for 1 week. *Lactobacilli.* Plate count (double plates) on the medium of Rogosa *et al.* (ref. 4) incubated at 37° C. for one week. *Enterococci.* Determined by M.P.N. method in Hajna and Perry's (ref. 5) S.F. medium incubated at 45° C. for 48 hr. *Coliform organisms.* Determined by M.P.N. method in ordinary MacConkey broth incubated at 37° C. for 48 hr.

This work was largely exploratory. Extension of the types counted and refinement of method might have yielded more information, yet it is probably fair to conclude that parabiotic rats may be closely linked but show as much 'between animal' variation in their fæcal organisms as comparable separate animals.

This work was done in the Department of Animal Nutrition at Cornell University, Ithaca, New York,

Growth of Bovine Amniotic Ectoderm as a Cell Monolayer on Glass and its use as a System for Virus Multiplication

It has been found in this laboratory that monolayer cultures of cells on glass can be prepared successfully from bovine amniotic membranes. Such cultures have proved to be suitable for differential growth-curve experiments with the virus of foot-and-mouth disease in which frequent changing of the medium is necessary. The yields of virus obtained were essentially similar to those obtained with cell suspensions or monolayer cultures derived from adult bovine tongue tissue. This success, and that of Zitser *et al.*[1] with similar monolayer cell cultures from human amnion in growing the virus of poliomyelitis, suggest the more extended use of fœtal membranes for the study of mammalian viruses, and particularly those with a very restricted host or tissue susceptibility.

Pregnant bovine uteri are obtained from the abattoir, if possible on the day of slaughter. The uterus is first washed with a 1 : 100 dilution of a quaternary ammonium compound, 'Deciquat' (The British Hydrological Corporation), and then with sterile physiological saline; the uterus and fœtal membranes are then incised with aseptic precautions. When the amniotic fluid has been collected for use as a culture medium[2], the fœtus is removed and the amnion stripped from the chorio-allantois. On removal of the amnion, it is placed intact in a flask containing either a solution of trypsin, if to be used at once, or amniotic fluid if to be stored for future use. Storage at 4° C. in amniotic fluid, with subsequent satisfactory growth of cells, has been carried out for periods up to nine days.

For the preparation of cell suspensions, a 0·25 per cent solution of trypsin ('Difco' 1 : 250) in a calcium- and magnesium-free modified Tyrode's solution[3] is employed, with incubation for 1–3 hr. at 37° C. During incubation the flask is agitated to assist the separation of cells and, on completion, an excess of the modified Tyrode's solution is added to the flask. The amnion is removed to another flask containing sterile modified Tyrode's solution for washing to ensure removal of all separated cells. The cell suspension from the first flask plus the washing fluid from the second flask are pooled and allowed partially to sediment, or it is filtered through stainless steel mesh to remove the amniotic pustules and other large fragments of tissue. The decanted or filtered cell suspension is then centrifuged at 1,000 rev./min. for 2 min. and the cell deposit resuspended in amniotic fluid plus 10 per cent ox serum to give a concentration of approximately 10^6 cells per ml. It is unnecessary to wash the cells to remove trypsin if ox serum is incorporated in the growth medium.

An amnion from a fœtus of 10–30 cm. head-rump length yields approximately 100 ml. of a suspension containing 10^6 cells per ml., that is, sufficient to inoculate ten 80-mm. Carrel flasks. These cell suspensions, even after prolonged exposure to trypsin, contain a large number of cell clusters which do not readily break down further. For purposes of cell counting, clumps of ten or more cells are counted as ten, and a suspension containing nominally 10^6 cells per ml. usually includes approximately 3×10^4 such clumps per ml. On inoculation into a flask, these cell clumps become attached to the glass and within 48 hr. an intact sheet of cells develops between them. After a further two or three days incubation at 37° C., the cell clusters become detached from the glass, leaving behind a very regular, intact monolayer sheet of cells. The paucity of mitotic cells in stained preparations, coupled with the rapidity with which the monolayer is formed, suggest that the bulk of the cell sheet is produced by migration of cells from the cell clusters rather than by cell division. If a more dilute seed inoculum is used, an extensive cell sheet develops within 48 hr. around the cell clusters, but it usually takes many more days for these discrete growth areas to become confluent and the resulting cell sheet is invariably very irregular and fenestrated, with a wide variation in cell morphology and size.

A monolayer produced from a heavy seed inoculum consists of an intact sheet of polygonal ectodermal cells, with an optically clear, very transparent cytoplasm. In living cultures nuclei can be seen, but the cell borders can be distinguished only faintly. In methanol-fixed preparations stained by May–Grünwald–Giemsa, only the nuclei could be identified against a homogeneous, palely stained background of cytoplasm.

By a direct count of nuclei per microscopic field of known area, total values of about $2 \cdot 5 \times 10^6$ cells are obtained for mature cell sheets in 80-mm. Carrel flasks.

Satisfactory growth of cells occurs when amniotic fluid is used alone, but the cell sheets have remained intact for a longer period if bovine serum is added to a concentration of 10 per cent. No advantage was apparent following the addition of bovine embryo extract. Antibiotics are added to the amniotic fluid at the time of collection (200 units of penicillin and 200 μgm. of streptomycin per ml.).

Amniotic membranes from fœtuses of 10-cm. head-rump length to nearly full term have been used with no apparent difference in rate of growth or susceptibility to infection by foot-and-mouth disease virus. In general, because the amniotic fluid from older fœtuses is not suitable as a culture medium, only fœtuses of 10–30-cm. head-rump length are used. On several occasions, fœtuses have been successfully employed following storage *in utero* overnight at 4° C.

Following inoculation of excess virus to cells, amnion cultures have usually shown cytopathogenic changes by 24 hr., progressing to complete degeneration by 48 hr. Occasionally, however, similar cultures have continued to release virus at a fairly constant rate for at least 60 hr. before showing evidence of cytopathogenic change. The irregularity of the time of appearance of cytopathogenic changes, together with the fact that mature cultures, even when stained with neutral red, are almost invisible to the naked eye, suggest that bovine amnion monolayers would not be particularly suitable for the titration of the virus of foot-and-mouth disease using Dulbecco's plaque counting method[4], recently shown in this Institute by Sellers[5] to be possible with the virus of foot-and-mouth disease using monolayers of pig kidney cells.

Although infections with recognized pathogenic agents such as *Rickettsia burneti*, *Brucella abortus*, *Vibrio foetus*, etc., could occur following the use of amniotic membrane or amniotic fluid from a naturally infected fœtus, no evidence of such infection has been observed in this series of cultures prepared from more than twenty-five bovine fœtuses.

Isolation of β-Dihydroequilin and α-Dihydroequilenin from the Urine of Pregnant Mares

In 1937, Hirschmann and Wintersteiner[1] reported the isolation of 17-dihydroequilenin from the urine of pregnant mares and expressed surprise that no evidence of the presence of dihydroequilin was obtained. (The nomenclature used here is that employed by Carol and his co-workers[3,4,6].) Afterwards, the presence of β-dihydroequilin was detected in material derived from pregnant mares' urine by the dioxane hydrolysis procedure of Grant and Beall[2], but isolation was not effected[3].

We now wish to report the isolation of large quantities of pure β-dihydroequilin from two different concentrates of conjugated œstrogens prepared from pregnant mares' urine collected respectively at mid-pregnancy (approximately the sixth month of pregnancy) and at late pregnancy (approximately the ninth month of pregnancy). It was found that in both instances the proportion of β-dihydroequilin present exceeded the proportion of β-œstradiol. No α-dihydroequilin was found in either concentrate.

The findings of Hirschmann and Wintersteiner[1] were confirmed by the isolation of large amounts of β-dihydroequilenin from both concentrates, but in addition to this α-dihydroequilenin was also obtained. The latter appears to be present in such small proportion that it cannot be considered a major constituent of the naturally occurring œstrogens in pregnant mares' urine.

The concentrates of conjugated œstrogens were prepared by solvent extraction of pregnant mares' urine. Predominantly non-ketonic material was isolated by counter-current distribution methods. This non-ketonic, conjugated material was hydrolysed by heating for 1 hr. at *p*H 1 on the water-bath, freed from ketonic material by a Girard separation, and a phenolic, non-ketonic fraction isolated by extraction into sodium hydroxide. This phenolic, non-ketonic fraction, which was a mixture of œstrogenic diols, was finally separated into its components by the chromatographic methods described by Carol, Haenni and Banes[4] employing sodium hydroxide on 'Celite' (manufactured by the Johns Manville Co.) as the immobile phase and benzene as the mobile phase. A concentrate of mixed conjugated œstrogens, giving a response by the Kober procedure equivalent to 100 gm. of sodium œstrone sulphate, fractionated by the methods described above, gave a phenolic, non-ketonic fraction which yielded 3 gm. of crystalline β-dihydroequilin (melting point 205–206°), identical with the β-dihydroequilin prepared by Carol, Haenni and Banes[4] by reduction of equilin with aluminium *iso*propoxide, and 1 gm. of β-dihydroequilenin (melting point 216–217°), identical with the material originally isolated by Hirschmann and Wintersteiner[1]; further quantities of β-dihydroequilin could also be isolated from various other side-fractions. Products were characterized by infra-red examination, preparation of derivatives and by analysis.

Throughout laboratory operations care was taken to avoid prolonged exposure of material to strongly acidic conditions. When this precaution was not taken, compound 3 of Hirschmann and Wintersteiner[1] was isolated in addition to β-dihydroequilenin and β-dihydroequilin and was presumably formed by isomerization of the latter in accordance with the findings of Banes, Carol and Haenni[5].

We shall publish this work in greater detail elsewhere.

Mating Reaction in Yeast

A preliminary study has been made of the mating mechanism of haploid cells of *Saccharomyces cerevisiae*. Three haploid pairs were used: one pair from Dr. C. C. Lindegren and the others derived from two strains of baker's yeast (Lindegren's α = plus; *a* = minus mating type in Fowell's nomenclature).

Lindegren's discovery[1] that stable haploid clones of two mating types could be derived from the spores of certain strains of baker's yeast made it possible to investigate Winge's suggestion[2] that conjugation is hormone-controlled. When haploid cultures of opposite (plus and minus) mating types are mixed, or cells are paired on an agar film, the cells may put out hyphal ('copulatory') processes; and when these meet, fusion may occur and a dumb-bell-shaped zygote be formed, from which diploid cells may be budded. This sequence of events constitutes the mating reaction, and a cell which puts out a copulatory process may be said to show a mating response.

Experiments in which a plus cell was placed close to a minus cell and allowed to grow on a malt agar film in a moist chamber[3] showed that the mating reaction is probably hormone-controlled, since a

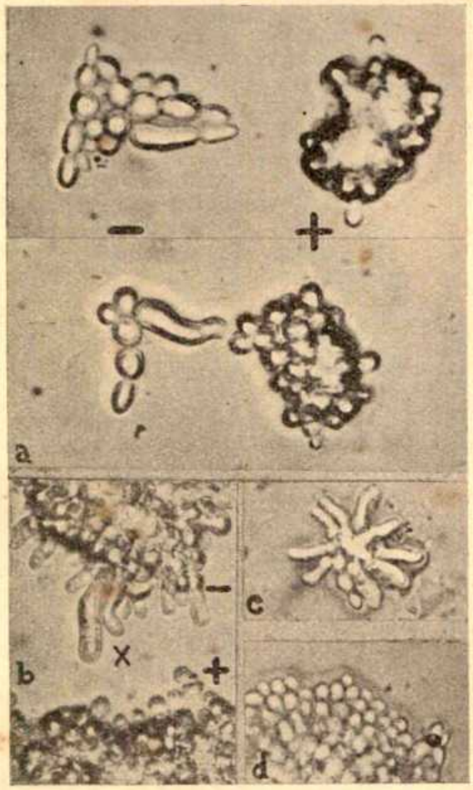

Fig. 1. (*a*) Two pairs of haploid cells, after incubation on a malt agar film; the cells of minus mating type show a mating response. × 480. (*b*) Parts of larger colonies, as (*a*). Both colonies were afterwards removed, and fresh minus cells were placed at point *X*. × 400. (*c*) Minus cells, after incubation on the agar at point *X*, show a mating response. × 400. (*d*) Fresh minus cells, showing normal morphology. × 400

mating response developed without contact between cells of opposite mating type; but it was found that only the minus cells put out copulatory processes (Fig. 1,*a*). In several experiments involving more than a hundred pairings of three pairs of haploids from different strains of yeast, plus cells never responded on a solid medium. The mating reaction occurred only after mutual interaction between a plus and a minus cell; but an agar surface from which sexually reacting cells had been removed could induce copulatory processes in minus cells added later (Fig. 1, *b*, *c*), but not in plus cells. However, on only one occasion was a mating reaction observed in a minus culture separated from a plus culture by a collodion membrane. In liquid medium, it should be noted, both plus and minus cells may develop copulatory processes.

The investigation is continuing, with particular attention to the isolation of chemical substances involved in the mating reaction. So far, an active culture filtrate has not been obtained from a mating mixture.

Viability and Developmental Capacity of Eggs from Immature Mice treated with Gonadotrophins

SEXUALLY immature mammals induced to superovulate and mate following gonadotrophin treatment provide a convenient supply of fertilized mammalian eggs for experimental purposes. The time of their ovulation is known and is independent of diurnal regulation. The large number of eggs recoverable from a single superovulated female can be expected to contain less genetical and physiological variability than an equal number from several mature donors. Also, when egg recovery necessitates killing females, the economy of using immature animals is realized in greater egg productivity and in a shortened generation interval. It is important, therefore, to establish whether eggs from ovulations induced in immature females are of normal viability and developmental capacity. Previous evidence[1-3] on this problem is not decisive in that it lacks direct comparisons with spontaneously ovulated eggs, from adult females, developing in similar uterine environments. The present work was intended to meet these requirements.

Genetically tagged eggs from superovulated and mated immature mice[3] were transferred as 3½-day morulæ or blastocysts to the uteri of seventy-four adult recipients (each having borne one litter) in which ovulations and matings with fertile males were synchronous with those of the donors. A control series, run concurrently with the first, consisted of eighty-three similar transfers of eggs spontaneously ovulated by mature donors. Fifty-eight hosts from the first series and sixty-three from the control group became pregnant and were autopsied at 18½ days gestation. Fœtuses from transferred and native eggs were counted in each uterine horn, and body-weights to the nearest 0·01 gm. were taken after severing the umbilicus and removing embryonic membranes and surface fluid.

Donor and recipient matings were so arranged that fœtuses from transferred and native eggs, though distinguishable by presence or absence of eye pigmentation, were otherwise similar in genetic background. Donor and recipient females were from the same highly fertile albino stock. Males were from the inbred albino strain *A* and from a homozygous non-albino stock derived by repeated back-crosses to strain *A* with forced segregation at the albino locus. The genetic tags for transferred and native eggs were reversed for half the experimental and control transplants.

Viability of eggs from immature mice. A comparison of viability of eggs from immature and mature donors is made in Table 1 as percentage survival of transplanted blastocysts to living fœtuses at 18½ days gestation. Most transfer operations were bilateral, and percentage survival has therefore been computed within uterine horns rather than within hosts. (Transuterine migration of eggs[4,5] appears to be rare in the stocks used; only one case was observed among those 124 genetically tagged eggs which survived in forty-one uterine horns from unilateral transfers of 194 eggs.) Among hosts becoming pregnant, the incidence of horns with no transferred eggs surviving was greater than could be accounted for by chance occurrence; an estimation that whole inoculum loss of eggs occurs in 20–25 per cent of transplants is consistent with the data. Consequently, in Table 1 a separate column is given for percentage survival

Table 1. Comparative Viability of Eggs from Immature and Mature Mice
Percentage survival to $18\frac{1}{2}$-days gestation of blastocysts transplanted to mated adult recipients

		Survival in recipients becoming pregnant			Survival in horns with one or more fœtuses from transplanted eggs		
Source of transplanted eggs	No. of eggs transplanted per horn	No. horns receiving eggs	Total eggs transplanted	% survival to $18\frac{1}{2}$ days	No. horns receiving eggs	Total eggs transplanted	% survival to $18\frac{1}{2}$ days
Immature donors	4	53	212	35·85	35	140	54·29
Mature donors	4	40	160	38·75	30	120	51·67
Immature donors	2–6	88	377	40·58	63	272	56·25
Mature donors	2–6	86	322	48·76	63	255	61·57

in horns with one or more transferred eggs surviving. In all transplants (two to six blastocysts per horn), the comparative survival-rates of eggs from immature and mature donors show a divergence which may be a consequence of the difference in mean numbers of eggs per inoculum. Transplants of four eggs per horn were the most common, and the corresponding percentage survivals of eggs from immature and adult donors, of 35·85 and 38·75 per cent, respectively, are strong evidence for the normal viability of eggs from ovulations induced in immature mice.

Developmental capacity of eggs from immature mice. The developmental capacity of eggs transplanted from immature donors has been compared with that of spontaneously ovulated, untransplanted eggs developing in the same uterine environment, that is, eggs native to the adult recipients. Hosts to $3\frac{1}{2}$-day eggs transplanted from adult donors provide a control for effect of transplantation on subsequent development. Comparisons were made within litters, and for each sex, of differences between mean weights of $18\frac{1}{2}$-day fœtuses from transferred and native eggs. From these within-litter differences, weighted according to relative numbers of fœtuses, calculations were made of the best estimates of mean differences in weight and their standard errors (Table 2). Neither the mean difference in weight between fœtuses derived from eggs of immature and mature females, nor that between fœtuses from transplanted and untransplanted eggs of mature females, varied significantly from zero. On the basis of the overall estimate of mean weight difference, $-0{\cdot}017 \pm 0{\cdot}011$ gm., if a retarding effect of transplantation on embryonic growth exists, it is most unlikely to exceed 0·04 gm. ($P = 0{\cdot}05$) or 3 per cent of the mean weight of native embryos, 1·23 gm. It was concluded, first, that transplantation of $3\frac{1}{2}$-day mouse eggs does not appreciably affect their subsequent embryonic growth in a host uterus of corresponding gestational stage and, secondly, that the developmental (growth) capacity of eggs from immature mice treated with gonadotrophins closely approximates that of eggs from spontaneous ovulations in adult mice.

Table 2. Developmental Capacity of $3\frac{1}{2}$-day Eggs transplanted from Immature and Mature Mice
Comparisons within litters of weights of $18\frac{1}{2}$-day fœtuses from transplanted eggs (immature and mature donors) and eggs native to the adult recipients

Source of transplanted eggs	Sex of fœtuses	No. litters for weight comparisons	No. fœtuses from trans. eggs (T)	No. native fœtuses (N)	Best estimate of mean difference in wt. (T–N) and stand. error (gm.)
Immature donors	♀ ♂	37 39	79 74	107 139	$-0{\cdot}005 \pm 0{\cdot}020$ $-0{\cdot}037 \pm 0{\cdot}020$
Mature donors	♀ ♂	35 36	69 70	119 128	$-0{\cdot}013 \pm 0{\cdot}029$ $-0{\cdot}011 \pm 0{\cdot}016$

I am grateful to Dr. R. A. Beatty for encouragement and supervision, to Prof. C. H. Waddington for facilities provided, and to Dr. M. N. Runner for instruction in transplantation techniques. This work, which will be published in detail elsewhere, is supported by a grant from the Jackson Memorial Laboratory, Bar Harbor, Maine, U.S.A.

Reduction in Growth of Clover due to Applied Molybdenum

In the course of co-operative investigations into problems of pasture establishment on coarse Taupo pumice, an observational minor-element trial was superimposed upon clover inoculation trials laid down by the Grasslands and Plant Disease Divisions, Department of Scientific and Industrial Research, N.Z. The soil was Kaingaroa sandy and gravelly sand of pH 5·7 and low in available nutrients, derived from rhyolitic pumice deposited less than two thousand years ago.

Seed and serpentine superphosphate (3 cwt./acre) or, in one treatment in replicate A, a serpentine superphosphate/lime mixture containing 12 per cent lime, were 'roller drilled' in on March 19, 1954. 'Roller drilling' followed by brush harrowing covered the seed and fertilizer to a depth of about 1–$1\frac{1}{2}$ in. Minor elements (boron, sulphur, zinc, copper, vanadium, manganese, cobalt, singly and all combined and all crossed with sodium molybdate at $2\frac{1}{2}$ oz./acre) were then watered, or in the case of sulphur, dusted on. Afterwards, 1 cwt. muriate of potash and 3 cwt. (spring 1954) and $1\frac{1}{2}$ cwt. (autumn 1955) per acre of double superphosphate were applied.

Table 1. Herbage Wet Weight (lb. per 100 ft. × 20 in.; Cut March 3, 1955

Treatments	Replicate A No Mo	Replicate A + Mo	Replicate B No Mo	Replicate B + Mo
Uninoculated + serp. super	18·1	7·0	16·2	8·0
Inoculated + „ „	20·3	13·7	27·5	9·7
„ + lime/serp. super	18·7	20·3	—	—
Available soil Mo (Grigg) p.p.m.	0·07	0·18	0·07	0·34
Total soil Mo (p.p.m.)	—	— 0·51 —		—

Table 2. Plant Analyses

	P (%)	N (%)	S (%)	K (%)	Na (%)	Mg (%)	Ca (%)	Mn (p.p.m.)	Cu (p.p.m.)	Mo (p.p.m.)
White clover, no molybdenum	0·22	3·4	0·21	2·5	0·08	0·30	1·4	146	6·0	0·3
White clover, + molybdenum	0·23	3·5	0·22	2·7	0·07	0·30	1·3	148	6·9	1·0
Red clover, no molybdenum	0·13	2·2	0·14	1·5	0·03	0·35	1·5	155	6·2	0·36
Red clover, + molybdenum	0·14	2·6	0·15	1·9	0·03	0·34	1·4	189	8·7	0·5

No effects due to minor elements were seen on November 17, 1954. But on December 17, 1954, it was obvious that molybdenum was severely depressing growth on replicate *B* and by February 11, 1955, the same was true of replicate *A*, excepting where the lime/serpentine superphosphate mixture had been used. The clovers showed no abnormal visual symptoms. The effect continues at the time of writing. There have been no consistent effects due to other minor elements and no obvious interactions with molybdenum. Relevant measurements are given in Tables 1 and 2.

Both total and available soil molybdenum were relatively low, and plant molybdenum was normal to low. There appears to be no possibility of a direct toxic effect. Both inoculated and uninoculated clovers were depressed, more especially in replicate *B*, where the soil-available molybdenum, for some unknown reason, was higher. The results of analyses for plant constituents given in Table 2 show no gross abnormalities. When cut, the clovers, especially the red clover, had flowered and were stalky. This stage of growth at cutting may explain the rather low phosphorus, nitrogen and sulphur contents. The effect of a small amount of lime completely offset the depression due to molybdenum without greatly altering any plant constituent measured.

An attempt to reproduce this depression under glasshouse conditions has failed.

It is difficult to conceive of any mechanism which would account for this unusual happening. The cause probably lies within the general field of minor element interactions.

A Small-scale Quality Test in Wheat Breeding

Dr. L. Zeleny, United States Department of Agriculture, Washington, D.C., has developed[1] and improved a lactic-acid wheat-flour sedimentation test for the grading of bulk wheat for quality. This test is in use at this Division as an aid to selection for high baking-quality wheats. In the preparation of the flour for the sedimentation test, wheat grain is passed through a 'C. and N. Junior' laboratory mill. By suitable pulleys the speed of the beaters is built up to approximately 14,000 rev./min. A metal screen fitted to the bottom of the mill has holes $\frac{1}{16}$ in. in diameter: eight holes to one inch. The ground wheat is sieved for $1\frac{1}{2}$ min. through cloth mesh 9×× using a 'Gallenkamp' laboratory shaker fitted with a time switch. The general procedure of the test follows that recommended by Dr. Zeleny (private communication).

The first application of the test was in the selection of good-quality single-plant progenies from a hybrid line. This line (derived from a single plant in F_2) had proved by F_{12} to be superior in yield and other agronomic characters to the standard New Zealand variety in large replicated trials in many districts; but was inferior in baking quality. One thousand single-plant progenies from this line were grown in short rows of twenty-five plants, and the sedimentation test was applied to the bulked grain from each row. Only ten progenies with high sedimentation scores were found. In the following year the residue of seed from these ten progenies was sown at wide spacing, to provide sufficient grain for a baking test. The baking score of the test loaves, based on loaf volume and crumb texture, was better than that of the standard variety.

It has been considered necessary to establish the validity of the sedimentation test over a range of varieties and localities in New Zealand. In 1954, sedimentation test figures were correlated with the baking scores of sixteen samples of one variety drawn from replicated field trials in different districts ($r = 0\cdot 89^{**}$). In 1955, samples were drawn from eight similar trials, each with seven varieties, in different localities. After the elimination, in the analysis, of differences due to varieties, high correlations were obtained over all localities between sedimentation test and two other tests of baking quality (Table 1).

Table 1

	Correlation coefficient
Sedimentation vs. baking score	0·88**
Sedimentation vs. total nitrogen (Kjeldahl)	0·85**
Total nitrogen vs. baking score	0·86**

It was found in the analysis of the set of trials, after the elimination of differences due to locality and error, that for varieties as a group, the correlation coefficient between the sedimentation test and baking score was only 0·08. Therefore it would appear that a calibration for individual varieties would be necessary before the general application of the sedimentation test. In a more extended series of trials covering further localities, the correlation coefficients for individual varieties ranged from 0·80 to 0·93. A graphical representation of the relationship between baking score and sedimentation test shows a set of variety regression lines which appear on preliminary evidence to be parallel.

The method has proved useful in the selection of single plants, grown at wide spacing, from hybrid bulks in the F_8 and F_9 generation. About 2 per cent. of the material sown is selected on agronomic characters; the individual plants are threshed, seventy-five grains are reserved for sowing, and the remainder are milled for the sedimentation test. 13 gm. of wheat, yielding 7·5 gm. of flour, are required for each test, but a less accurate test can be made on 8 gm. Grain from plants with sedimentation scores above the average for the particular bulk is sown for further observation. It is not desirable to set high limits for the selection of plants from each bulk: the test is accurate, but the relation between test score and baking score differs between varieties, and therefore between plants within a hybrid bulk. The value of small-scale quality tests is to allow the rejection, in the early stages of selection, of those plants or progenies which would have proved to be of poor baking quality. It has been found that, whereas the sedimentation test accentuates differences in quality at the higher end of the scale, other small-scale tests in use are not sufficiently critical at this level.

The application of the sedimentation test to hybrids in advanced generations has been successful and the use of the test in the early generations of wheat crosses is under investigation. It may be possible to select for flour quality at the same time as for other agronomic characters.

Abnormal Hæmoglobins in the Kasai Province of the Belgian Congo

Hæmoglobin C was first detected among American Negroes, and figures for its incidence range between 1·4[1] and 3 per cent[2]. As the anomaly seemed virtually absent in the white race, it was reasonable to suppose that the gene responsible for it had been imported from Africa in the times of slave trade. This was soon confirmed by a survey of Edington and Lehmann[3], who found hæmoglobin C to be present in 12 per cent of 200 hospital out-patients in Accra (Gold Coast). Recently, individuals with this hæmoglobin have been reported from French North Africa[4]. It is also known to exist in Liberia and in French West Africa (Neel, J. V., personal communication).

In East Africa, surveys for abnormal hæmoglobins among natives from Uganda[5], Southern Sudan and Tanganyika[6] did not provide any specimens of hæmoglobin C. In South Africa, hæmoglobin C was found in 2 out of 219 blood specimens of Cape 'coloured' individuals[7]. However, as Lehmann points out, these sporadic cases may be the result of the introduction of slaves from West Africa.

As no results for hæmoglobin C are available for Central Africa, we undertook an investigation at Luluabourg, a town of 40,000 inhabitants, situated in the Kasai Province to the south of the Congo Basin. Blood specimens for paper electrophoresis of hæmoglobin were obtained from 500 unrelated and unselected natives. Most of them were young adults belonging to the important Baluba tribe. The apparatus and the technique used were those already described by one of us[8]. In addition to electrophoresis, all specimens were examined for sickling in 2 per cent sodium metabisulphite.

Of the 500 samples tested, 148 (29·6 per cent) showed sickling. In all these instances the electrophoretic pattern was that of the heterozygous sickling trait. All other hæmoglobin samples showed a single component corresponding to normal adult hæmoglobin. The pattern of homozygous sickle-cell anæmia was not encountered in our sample. Although sickle-cell anæmia is a very common disease at Luluabourg (75 new cases were seen during the past ten months) we were never able to diagnose the disease in adults beyond the second decade.

Apart from this investigation, 35 further specimens were selected from patients suffering from different symptoms suggestive of sickle-cell disease. The hæmoglobin of one of these patients showed the electrophoretic properties of a hæmoglobin S–C mixture, and was thus diagnostic for sickle-cell hæmoglobin C disease. This patient was a male adult with slight anæmia, numerous target cells and a high percentage of red cells sickling *in vivo*. His chief complaint arose from a mutilating necrosis of the femoral head. A complete case report of this patient has been published elsewhere[9].

The anthropological significance of this sporadic case has probably no more value than those found in the Cape 'coloured' population. The patient was originally from the enclave of Cabinda situated a few miles to the north of the Congo estuary. As there has been for generations a busy trade between the natives of Cabinda and those of the Guinea coast, the occasional presence of hæmoglobin C is not surprising. This study in association with other surveys provides further evidence that the diffusion area for the gene of hæmoglobin C does not extend south of the equator.

This investigation was supported in part by State of Washington Initiative 171 funds for research in biology and medicine.

Orotic Acid as a Survival Factor in Rats Deficient in the Animal Protein Factors of Casein

Viviani *et al.*[1] have recently shown that orotic acid may be one of the growth factors for rats deficient in the animal protein factors of casein, but not for normal rats. These and previous[2,3] observations suggest a possible relationship between orotic acid and animal protein factors of casein. Therefore, in the present work, our investigations have been extended to the significance of prophylactic feeding of orotic acid upon the most dramatic aspect of the deficiency of animal protein factors of casein, namely, the high mortality of the newly born of the first generation and the total mortality of the second generation.

To this end, we have divided from weaning (21 days of age) thirty female rats of the Sprague–Dawley strain into three groups and placed them on the three experimental rations described in Table 1.

In these three groups of female rats and in the female rats of the subsequent filial generations, the survival of young from birth to weaning has been recorded. The results are reported in Table 2.

From the above results it appears evident that orotic acid may be a new factor for the survival of newly born rats deficient in the animal protein factors of casein.

Since orotic acid does not appear to be essential to survival, we think that orotic acid may be:

Table 1

Diets*	Basal	Devoid of casein animal prot. factors	Devoid of casein animal prot. factors + orotic acid
Ground cereals (wheat, maize, barley, oats, rye)	88	88	88
Crude rennet casein	5	—	—
Purified casein devoid of casein animal prot. factors (ref. 3)	—	5	5
Wheat germ	5	5	5
Calcium lactate	1·5	1·5	1 5
Sodium chloride	0·5	0·5	0·5
Orotic acid†	—	—	0·001

* The three diets are supplemented with carrots and fresh vegetables *ad libitum* twice a week.

† Orotic acid manufactured by Biochemical Inc., Co., Cleveland, Ohio

Table 2

Diets	Basal		Devoid of casein animal prot. factors		Devoid of casein animal prot. factors + orotic acid	
Generations	I	II	I	II	I	II
No. of animals	10	10	10	10	10	10
No. of young per litter	11	11	10·1	8·3	10·2	9·2
Mortality of young in 21 days (per cent)	2	2	72	100	6	7
Mean weight of young at 21 days (gm.)	48	48	32	—	46	43

(*a*) one of the animal protein factors ; (*b*) a precursor or a part of the animal protein factors, should the animal protein factors prove to be unique substances ; or (*c*) a substance with high sparing action on the animal protein factors of casein.

The Striped Marlin (*Makaira audax* Phillipi) in South Africa

Marlin fishes of the genus *Makaira* Lacépède, 1803, occur throughout almost all tropical and temperate seas, and are of interest not only to the scientist but are also the prime quarry of the big-game angler. The systematics of these large wide-ranging fishes is troublesome, since few scientists can hope to examine an adequate series of fishes from over a wide area, and the number of species accepted by workers varies from three to the patently unacceptable sixteen of Jordan and Evermann (1926).

Makaira audax Phillipi, 1887, the well-known 'striped marlin', has hitherto been regarded as confined to the wide area of the Pacific. Although variable in colour and markings more or less according to where it occurs, and though these variations have been described as different species, the species is in effect sharply defined by the elevated front lobe of the dorsal fin, which is never less than, but almost always higher than, the depth of the body below, and about one and a third in the upper caudal lobe. The lateral line is virtually obsolete. The spear is slender, its width at tip of lower jaw about one-seventh of the preocular length of the mandible. The body is usually clearly striped.

By most American workers this species is regrettably labelled *M. mitsukurii* Jordan and Snyder, 1901, even though *audax* Phillipi clearly has priority.

This characteristic fish has been reliably recorded from the Western Pacific coast of America, Hawaii, Fiji, the seas about Japan, the Philippines, Australia and New Zealand. It has not before been certainly recorded from the Indian Ocean. Morrow[1] states that specimens of this species were seen alive in the sea off the coast of Kenya, but not captured. He also regards *Makaira brevirostris* (Playfair), 1866, as possibly this species ; but from Playfair's description and the illustration[2], it is quite clear that Playfair's fish was a specimen of the widespread *indicus* Valenciennes, 1831.

LaMonte[3] records *Makaira mitsukurii* J. & S. (= *audax*) from Ceylon on the basis of a brief description and an illustration by Deraniyagala[4]. But it is quite plain that this Ceylon fish cannot be *audax*. In any event there is confusion, since in the first paper the fish figured is clearly only about 6 ft. in length, whereas the dimensions given in the "Atlas" show it as almost 12 ft.

The present account is based on a specimen captured by an angler off Mossel Bay, South Africa, at about lat. 34° 5′ S., long. 22° 12′ E. It was taken to Cape Town; but as there was doubt about its identity, on request of the Press I went by air to Cape Town to examine the fish, when I found that it was unquestionably *audax*. This is far south for any marlin to be captured, but is in line with their presence off New Zealand and the west coast of South America. It is noteworthy that specimens of the black marlin, *M. indicus* Valenciennes, have also been captured and many more have been seen at other parts along the shores of South Africa.

The main dimensions of this 160-lb. Mossel Bay specimen, in inches, are as follows : total length, 108 ; standard length, 89 ; snout tip, to eye, 21 ; to hind margin opercle, 34 ; to anal origin, $61\frac{1}{2}$; depth of body, $13\frac{1}{2}$; height of dorsal lobe, 18 ; of anal lobe, 11 ; upper caudal lobe, 24 ; lower, 23 ; tail spread, $34\frac{1}{2}$; pectoral fin, $20\frac{3}{4}$; pelvic fin, $14\frac{3}{4}$; width of spear at tip lower jaw, $1\frac{3}{16}$, at two inches from apex, only $\frac{3}{8}$. The colour was brilliant purple, the numerous conspicuous transverse stripes faint lavender. The specimen is in my possession and will be mounted for retention in this Department.

Assistance from the South African Council for Scientific and Industrial Research has enabled this specimen to be preserved.

Wednesday, April 25

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 3 p.m.—Annual General Meeting.

Royal Meteorological Society (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Annual General Meeting. Dr. R. C. Sutcliffe: "The Moisture Balance of the Atmosphere" (Presidential Address).

British Institution of Radio Engineers, London Section (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C.1), at 6.30 p.m —Mr. M. Smith: "Radio and Television Interference—Its Growth and Effects".

Society of Chemical Industry, Plastics and Polymer Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p m.—Dr. N. Grassie: "The Role of Abnormal Leakages in Polymer Degradation".

Institute of Metals (at 4 Grosvenor Gardens, London, S.W.1), at 6 45 p.m.—Prof. Cyril S. Smith (University of Chicago): "The Beginnings of Metallography".

Society for Visiting Scientists (at 5 Old Burlington Street, London, W.1), at 7.30 p.m.—Discussion Meeting—"Vital Statistics in Psychiatry". Chairman: Prof. Aubrey J. Lewis. Speakers: Dr. Vera Norris, Prof. L. S. Penrose, F.R.S., and Dr. Peter Sainsbury.

Thursday, April 26

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Meeting for election of Foreign Members. Mr. R V. Coxon and Mr. R. J. Robinson: "Carbohydrate Metabolism in Blood Cells Studied by Means of Isotopic Carbon"; Mr. J. T. Davies, Mr. D. A. Haydon and Sir Eric Rideal, F.R.S.: "Surface Behaviour of *Bacterium coli*".

Royal Society of Arts, Commonwealth Section (at John Adam Street, Adelphi, London, W.C.2), at 5.15 p.m.—Mr. C. M. Gray: "The Snowy Mountains Scheme".

Chadwick Trust (at the Royal Society of Health, 90 Buckingham Palace Road, London, S.W.1), at 5 30 p.m.—Mr. J. Rawlinson: "The Centenary of London's Main Drainage System" (Chadwick Public Lecture).*

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5.30 p.m.—Prof. A. C. B. Lovell, F R.S.: Forty-seventh Kelvin Lecture on "Radio Astronomy".

University of London (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Prof. A. Andreotti (University of Turin): "The Problem of Complete Intersections" * (Further Lecture on May 3.)

Friday, April 27

Institution of Mechanical Engineers (joint meeting with the Institution of Civil Engineers and the Institution of Electrical Engineers, at 1 Birdcage Walk, Westminster, London, S.W.1), at 5.30 p.m.—Sir Maurice Bowra "The Impact of Engineering on Society" (Graham Clark Lecture).

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Sir Harold Spencer Jones, F.R.S: "Edmond Halley and His Work"

Saturday, April 28

British Psychological Society, Social Psychology Section (in the Psychology Department, Birkbeck College, Malet Street, London, W.C.1), at 2.30 p.m.—Symposium on "Recent Developments in Survey Methods"

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer (with research experience and preferably industrial experience) in Organic Chemistry; and an Assistant (Grade B) in Physics—The Registrar, Nottingham and District Technical College, Shakespeare Street, Nottingham (April 25).

Physicist (with an honours degree) in the Department of Physics Applied to Medicine, for work concerned with the application of radioactive isotopes in clinical investigations—The Secretary, Physics Department, Middlesex Hospital Medical School, London, W.1 (April 25)

Analyst (with a university honours degree or Associateship of the Royal Institute of Chemistry, and experience in a Public Analyst's or similar laboratory, preferably dealing with water and sewage analysis)—City Analyst, 123 Mount Pleasant, Liverpool 3 (April 28).

Assistant Lecturer or Lecturer (with specialist knowledge in some aspect of microbiology or plant pathology) in the Department of Botany—The Registrar, The University, Liverpool (April 28).

Principal Scientific Officer (with a degree of high standard in mathematics or equivalent qualifications, extensive experience of theoretical work in supersonic aerodynamics, and ability to direct the work of others) in the Aerodynamics Division, Weapons Research Establishment, Salisbury. South Australia to initiate and be responsible for research, especially of a mathematical nature, in supersonic and transonic flow, and to collaborate with staff carrying out experimental work in this field, and to exercise supervision over the work of other scientific staff—The Senior Representative (A.P.42/1), Department of Supply, Australia House, Strand, London, W C 2 (April 30).

English Electric Research Fellow in Aeronautics for postgraduate research into problems of vibration or stability and control of aircraft—The Warden, College of Aeronautics, Cranfield, Bletchley, Bucks (May 1).

Assistant Advisory Bacteriologist (with an honours degree in bacteriology or equivalent, and postgraduate experience) at Perth Sub-Station—The Secretary, Edinburgh and East of Scotland College of Agriculture, 13 George Square, Edinburgh (May 4).

Assistant Experimental Officer (with a degree in botany or an allied biological science) in the Department of Plant Breeding, to assist with cytological studies of horticultural crops—The Secretary, John Innes Horticultural Institution, Bayfordbury, Hertford, Herts (May 5)

Assistant Lecturer or Lecturer (preferably on the experimental side) in Physics—The Registrar, The University, Sheffield (May 5).

Mathematicians, Experimental Officer or Assistant Experimental Officer grade (preferably with a pass degree in mathematics, or at least H.S C (science) or equivalent) at the Ministry of Supply Ordnance Board, London, for work on ballistics (duties include analysis of experimental results and computation of gunnery data)—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S W.1, quoting A 126/6A (May 5).

Assistant Lecturer (with a good honours degree and some research experience) in Physical Chemistry—The Registrar, King's College, Strand, London, W.C.2 (May 11).

Lecturer or Assistant Lecturer in Physiology—The Registrar, The University, Sheffield (May 12).

Soil Mineralogist (with a university honours degree in science, with chemistry and geology as major subjects, and preferably soil research experience) in the Division of Soils, Commonwealth Scientific and Industrial Research Organization, South Australia, to conduct research into the mineralogy of soils, as part of a programme relating to chemical properties with mineral composition—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting 270/123 (May 12).

Lecturer in Anthropology at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, May 14)

Scientific Officer (with a science degree of a university in the U K, with passes in biochemistry, zoology or botany, etc., and preferably relevant postgraduate experience) at the Blood Transfusion Centre, Oxford—The Medical Director, Regional Blood Transfusion Centre, Churchill Hospital, Headington, Oxford (May 14).

Scientific Officers (2) (with an honours degree in animal husbandry or equivalent qualification) for experimental work with hill sheep and cattle; and Scientific Officers (2) (with an honours degree in botany, agricultural botany or principles of plant husbandry) in the Botany Department—The Secretary, Hill Farming Research Organization, 48 Palmerston Place, Edinburgh 12 (May 14).

Plant Physiologist (with an honours degree in science or agricultural science and postgraduate research experience in plant physiology) in the Department of Plant Physiology, Waite Agricultural Research Institute, for research in the general field of carbohydrate metabolism of economic plants—The Registrar, University of Adelaide, Adelaide, South Australia (May 15).

Dr. Lee's Professor of Experimental Philosophy—The Registrar, University Registry, Oxford (May 17).

Assistant in the Department of Geography; and a Lecturer (with special knowledge in the geography of climate, soil and vegetation) in the Department of Geography—The Assistant Secretary, The University, Edinburgh (May 19)

Assistant Lecturer (preferably with special qualifications and experience in animal husbandry) in Animal Husbandry, at the School of Agriculture, Sutton Bonington, near Loughborough—The Registrar, The University, Nottingham (May 19).

Lecturer in Mathematics—The Secretary, The University, Aberdeen (May 19).

Lecturer (with special qualifications in applied mathematics, and preferably an interest in fluid dynamics) in Mathematics—The Registrar, The University, Manchester 13 (May 19).

ASSISTANT LECTURER IN PHYSICS—Prof. K. G. Emleeus, Queen's University, Belfast (May 20).

ASSISTANT LIBRARIAN (preferably science graduate with professional diplomas and experience), at the University College of Rhodesia and Nyasaland—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (May 21).

LECTURER (with training and research experience) IN MATHEMATICAL PHYSICS—The Registrar, The University, Birmingham (May 22).

HENRY BELL WORTLEY CHAIR OF METALLURGY—The Registrar, The University, Liverpool (May 26).

LECTURER (with training and experience in experimental physics) IN PHYSICS, at the University College of the West Indies—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (May 31).

SENIOR LECTURER (with a degree in science or engineering, with geology as a major subject, and field experience in mining and/or engineering geology, and preferably experience in mineragraphy and/or geophysical exploration) IN ECONOMIC GEOLOGY, at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, June 1).

BIOCHEMIST (Senior grade) to the Rochdale Group of Hospitals—The Group Pathologist, Birch Hill Hospital, Rochdale, Lancs.

BRITISH RUBBER PRODUCERS' RESEARCH FELLOW (with a good honours degree in engineering or physics, and industrial or research experience) for research into the mechanical properties of rubber—The Registrar, The University, Nottingham

ENGINEERS and PHYSICISTS (particularly with electronics) (Experimental Officer and Assistant Experimental Officer grades), in Experimental Establishments, in the London, Portsmouth and Weymouth areas, Cheltenham and Scotland—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.214/5A.

LECTURER (preferably with an honours degree, and teaching, research or industrial experience) IN PHYSICS; and an ASSISTANT LECTURER, Grade B (preferably with an honours degree, and teaching, research or industrial experience) IN PHYSICS—The Clerk to the Governors, Mid-Essex Technical College and School of Art, Market Road, Chelmsford.

LECTURER (specializing in palæontology-stratigraphy) IN GEOLOGY, and a LECTURER (specializing in petrology-mineralogy) IN GEOLOGY—The Acting Dean, College of Arts and Science, Baghdad, Iraq

LECTURER (with a degree or equivalent in microbiology or bacteriology, and preferably some experience of industrial applications) IN MICROBIOLOGY—The Secretary, Royal Technical College, George Street, Glasgow, C.1.

READER OR SENIOR LECTURER IN MECHANICAL ENGINEERING; a SENIOR LECTURER, LECTURER or ASSISTANT LECTURER IN MECHANICAL ENGINEERING; and a SENIOR LECTURER, LECTURER or ASSISTANT LECTURER IN CIVIL ENGINEERING, at the University College of Khartoum, Sudan—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1.

SENIOR LECTURER IN PHYSICS—The Secretary, Royal Technical College, Glasgow.

SENIOR LECTURER IN PHYSICS to teach up to B Sc. (Special) Degree standard—Northern Polytechnic, Holloway, London, N.7

SOIL SURVEYORS (with B.Sc (Agr.) or equivalent qualification) with the New South Wales Department of Agriculture, to carry out soil surveys in any part of New South Wales, prepare data and draft maps from surveys, laboratory work, etc.—The Agent General for New South Wales, 56 Strand, London, W.C.2.

TECHNICAL OFFICER (with a degree in botany or equivalent qualifications, and preferably practical experience of seed production) for herbage seed multiplication—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

TECHNICAL RESEARCH ASSISTANT IN THE BACTERIOLOGY DEPARTMENT—The Secretary, Queen Elizabeth College (University of London), Campden Hill Road, London, W.8.

LECTURES AND COURSES

TRAINING OF TECHNICAL TEACHERS

Applications are invited from men and women of about 25 years of age and over for admission to a One Year Course of Training as full-time teachers of Science, Mathematics and other Technical and Commercial subjects in technical colleges and other similar institutions. Applicants should have a university degree, be an Associate Member of a professional Institution, or possess qualifications such as higher national or higher school certificate, together with suitable experience in industry or commerce. The course begins in September, 1956. Recognized students pay no fees and are eligible for maintenance grants

Further particulars and application forms may be obtained from the following college on receipt of a stamped addressed foolscap envelope.

THE DIRECTOR, (S/3/34)

Huddersfield Training College,
Queen Street South,
Huddersfield.

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF MATHEMATICAL PHYSICS

POSTGRADUATE COURSE IN MATHEMATICAL PHYSICS

A postgraduate course in Mathematical Physics has been instituted. It is intended for graduates with a good honours degree in mathematics and subsidiary physics, who propose to take up work involving the practical application of mathematics to physical and similar problems. Candidates who are successful in the examination at the end of the course, will be awarded a Diploma in Mathematical Physics The course lasts for one session (October to July). The fee is £50 A limited amount of money is available for scholarships, which would contribute to maintenance and fees, in suitable cases.

Applications for admission to the course starting in October, 1956, should be made to the Registrar, The University, Birmingham, 15, as soon as possible.

G. L. BARNES,
Secretary

The University,
Birmingham, 15.

UNIVERSITY OF LONDON

A lecture on "Patterns of Innervation and Contraction in Striated Muscle" will be given by Dr S. W. Kuffler (Johns Hopkins Hospital) at 5 p.m. on May 2 at St. Thomas's Hospital Medical School, Albert Embankment, S E.1.

Admission free, without ticket.

JAMES HENDERSON,
Academic Registrar

UNIVERSITY OF LONDON

A course of two lectures on (i) "Morphogenetic Effects of Restricted Spectral Regions of Light in Plants" and (ii) "Some Plant Physiological Experiments Related to Horticultural Problems" will be given by Professor E. C. Wassink (Wageningen) at 5.30 p m. on May 2 and 3 at University of London, Senate House, W.C.1.

Admission free, without ticket.

JAMES HENDERSON,
Academic Registrar.

THE POLYTECHNIC

309 REGENT STREET, W.1

DEPARTMENT OF MATHEMATICS AND PHYSICS

A full-time course of four years' duration for The Polytechnic Diploma in Physics will commence in September, 1956. This diploma carries full exemption from the examination requirements for the Graduateship of the Institute of Physics (Grad. Inst.P.). Entrants should be at least 16 years of age and have attained the standard of the ordinary level of the G C E. examinations in appropriate subjects. Students who have reached the advanced level will be exempt from the first year of the course.

A prospectus giving full details of the course may be obtained on application to the Director of Education.

UNIVERSITY COLLEGE

LONDON

(GOWER STREET, W.C 1)

Professor G. H. von Wright (Helsinki) will give the Shearman Memorial Lectures entitled "Aspects of Modal Logic" on May 1, 3, 8, 10, at 5 30 p.m.

Admission free, without ticket.

E. A. L. GUETERBOCK,
Secretary.

UNIVERSITY COLLEGE

LONDON

FREE PUBLIC LECTURES, SUMMER TERM, 1956

Thursday, May 3, at 5 p.m., Professor N. L. Edson, The Intermediate Metabolism of Carbohydrate in the Mycobacteria.

Thursday, June 14, at 5.15 p.m., Professor Roy P. Forster, Active Transport in Cells of Mammalian Renal Tubules Studied *in vitro.*

Complete list of public lectures from Publications Officer, University College, London, Gower Street, W.C.1. (Stamped envelope required)

UNIVERSITY OF LONDON

A course of two lectures on "The Problem of Complete Intersections" will be given by Professor A. Andreotti (Turin) at 5.30 p.m on April 26 and May 3 at King's College, Strand, W.C.2

Admission free, without ticket

JAMES HENDERSON,
Academic Registrar

OFFICIAL APPOINTMENTS

The engagement of persons answering these advertisements must be made through a Local Office of the Ministry of Labour or a Scheduled Employment Agency if the applicant is a man aged 18 to 64 inclusive, or a woman aged 18 to 59 inclusive, unless he or she, or the employment, is excepted from the provisions of the Notification of Vacancies Order, 1952.

BRITISH COLUMBIA RESEARCH COUNCIL

UNIVERSITY OF BRITISH COLUMBIA

POST-DOCTORAL FELLOWSHIPS

Applications are invited for post-doctoral research fellowships in organic chemistry for a period of two or three years. The selected candidates would join a group engaged in synthetic work in the general nucleic acid field, under H. G. Khorana. These fellowships are of the value of $3,200 (income tax free) per year for single and $3,800 (income tax free) for married persons. Some allowance is made for travel.

Those interested should submit curriculum vitae and other information to

Dr. G. M. SHRUM,
Director.

B.C. Research Council,
University of British Columbia,
Vancouver, 8, B.C.

LEEDS COLLEGE OF TECHNOLOGY

COOKRIDGE STREET, LEEDS, 2

Principal: C. Chew, M.Sc Tech., F.R.I C.

DEPARTMENT OF ELECTRICAL ENGINEERING AND PHYSICS

Applications are invited for the post of Assistant Lecturer (man or woman) in Physics, duties to commence on September 1 next. Candidates should possess a good degree in physics and preferably have had teaching experience. Industrial or research experience would be an added recommendation. The post is graded "B" on the scale £525 by £25 to £820 per annum (men) or £475 by £20 to £655 per annum, plus equal pay instalments (women), together with full allowances for training, qualifications, teaching and industrial experience.

Further particulars and form of application, to be returned by April 30 next, may be obtained by sending a stamped addressed foolscap envelope to the Principal.

GEORGE TAYLOR,
Chief Education Officer.

Education Department,
Leeds, 1.

CITY OF LIVERPOOL EDUCATION COMMITTEE

CITY COLLEGE OF TECHNOLOGY

(Principal: E. G Edwards, B.Sc , Ph D., F.R.I C)

Applications are invited for the appointment of Lecturer in the Department of Physics and Mathematics Salary. Men, £965 by £25 to £1,065 per annum. Women, £772 by £20 to £852 per annum (Plus equal pay increments). (Burnham Technical Scales). Applicants should possess good graduate qualifications in physics, with industrial and/or teaching experience. Research experience would be an advantage.

Particulars of appointment and application forms (returnable as soon as possible), may be obtained from H. S. Magnay, M.A , Director of Education, 14 Sir Thomas Street, Liverpool, 1.

THOMAS ALKER,
Town Clerk and Clerk to the Local Education Authority. (J.4290)

DERBY AND DISTRICT COLLEGE OF TECHNOLOGY

Principal: T. Heap, Ph.D; M.Sc., F.R I.C, A.M.I I.A.

Applications are invited from graduates for the post of Assistant Grade B, to teach Biology in the Natural Science Department, duties to commence on September 1, 1956. Candidates should possess an honours degree in botany or zoology and be able to teach both subjects to the advanced level of the general certificate of education. Salary in accordance with Burnham Further Education Scale: Men £525 by £25 to £820; women £475 by £20 to £655, plus allowances for degree and training and increments for teaching and industrial experience. The scale for women is basic and subject to the recommendations regarding "equal pay."

Application forms and details of the post may be obtained from the Principal, Derby and District College of Technology, Normanton Road, Derby, by whom completed applications should be received within two weeks of the appearance of this advertisement.

UNIVERSITY OF BIRMINGHAM

Applications are invited for a Research Assistantship in the Coal Constitution Laboratory of the Department of Mining Candidates should possess a first-class or a good second-class honours degree in chemistry, or should be taking final examinations this year. Initial salary £350 a year. The assistant will be a member of a team carrying out research on the chemical constitution of coal, including the examination of the products of mild oxidative degradation of coal, and will be allowed to supplicate for a higher degree.

Applications should reach the Professor of Mining, The University, Edgbaston, Birmingham, 15, before May 11, 1956.

G. L. BARNES,
Secretary.

The University,
Birmingham, 15.

MINISTRY OF LABOUR AND NATIONAL Service: H.M. Inspectors of Factories (Class II). The Civil Service Commissioners invite applications from men and women for pensionable posts Age at least 21 and (unless exceptionally well qualified) under 30 on June 1 in the year of application with extension for regular service in H.M. Forces. London salary (including extra duty allowance where payable) £506 (at age 21), then according to age up to £669 at 26 or over, rising to £917. Somewhat lower outside London. A special increment of £25, within the scale, is granted after passing probation Higher posts filled by promotion from Class II. Duties include the enforcement of the provisions of the Factories Acts and Regulations affecting the safety, health and welfare of work-people and extend to all manufacturing industries and to certain other places, including docks, works of engineering construction and building operations. Candidates must normally be university graduates, preferably in engineering or natural science (or comparable technical qualification, e.g, A M.I.Mech E). Graduates in other subjects, including arts, are eligible. Works or other practical experience an advantage. Candidates without degrees (or comparable technical qualifications) who have good general or technical qualifications, and have had considerable works or other practical experience (especially in responsible positions) will also be considered. Application may be made at any time, and so long as there are vacancies suitable candidates will be interviewed—Particulars from Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting No. 280.

CHEMIST (BASIC GRADE) REQUIRED BY the Atomic Weapons Research Establishment, Aldermaston, Berks. Duties will include the control of water treatment plants, trade waste treatment and radio-active effluent treatment and disposal systems, special laundry for contaminated protective clothing and the decontamination of plant and equipment. The post may involve short tours of overseas duty. Applicants should have an honours degree in chemistry or the A.R.I.C. or equivalent qualifications and at least three years' experience in the industrial chemistry field. Experience of water treatment would be an advantage. Salary: £728 (at age 25) to £1,130 per annum Contributory Superannuation Scheme. Married officers now living outside the Establishment's transport area will be eligible for housing on one of the Authority's estates; alternatively assistance towards legal expenses incurred in house purchase may be payable; until housed a lodging allowance may be available.—Requests for application forms by postcard to the Senior Recruitment Officer at the above address not later than May 2. Quote reference 1104/34.

BAIRD & TATLOCK (LONDON) LTD.
FRESHWATER ROAD, CHADWELL HEATH, ESSEX

Pergamon Press Limited, with the co-operation and assistance of the Trustees of the Wellcome Trust, announce the forthcoming publication of Volume One of

The Collected Papers of Paul Ehrlich

IN FOUR VOLUMES INCLUDING A COMPLETE BIBLIOGRAPHY

This collection is compiled and edited by DR. F. HIMMELWEIT (with the assistance of MARTHA MARQUARDT) under the editorial direction of SIR HENRY DALE

This unique collection contains everything scientifically significant which EHRLICH actually published in any form and, in addition, acquires particular value from the inclusion of several important but hitherto unpublished documents, which he left in manuscript or typescript.

Contents of Volume One—HISTOLOGY, BIOCHEMISTRY AND PATHOLOGY

Practice and Theory of Staining in Histology—Cytology of the Blood in Health and Disease—Staining of Bacteria and its Application to Diagnosis—"The Oxygen-hunger of the Organism" and Allied Biochemical Studies—Pharmacology, Therapeutics and Toxicology—The Diazobenzene-sulphuric Acid and Dimethylaminobenzaldehyde Reactions.

Volume Two—IMMUNOLOGY AND CANCER RESEARCH Volume Three—CHEMOTHERAPY Volume Four—OBITUARY NOTICES AND PERSONAL TRIBUTES—BIBLIOGRAPHY WITH ANNOTATIONS—SUBJECT INDEX

Published Price of all Volumes (I–IV) is £24

Volumes I, II and III can be purchased separately at £7 each. Volume IV (not sold separately) will be available with any other volume at a cost of £5.

Pergamon Press 4 & 5 Fitzroy Square, London, W.1

GOVERNMENT SUPPORT FOR RESEARCH IN GREAT BRITAIN

THE report of the Advisory Council for Scientific and Industrial Research for the year 1954–55 (see p. 768 of this issue) discusses at some length the position of the research associations in the national organization for research; but this is only one of a number of major matters of policy that are dealt with in the report. During the year, the first financial year of the Department's five-year plan was completed, and the Advisory Council records that the provision of resources within the framework and terms of the plan has proceeded smoothly. The provision in the Ministry of Works Votes for services to the Department in 1955–56 is £2,039,200 against £1,497,500 in the previous year, the increase being due mainly to increased provision for major building works, notably for the National Physical Laboratory, the Mechanical Engineering Research Laboratory, the Radio Research Laboratory and the Building Research Station.

The one exception to the smooth implementation of the five-year plan is in regard to staff, the increase of 159 being again less than the 200 provided for in the plan. Continuous and expanded efforts were made to recruit suitable scientists, and the Advisory Council believes that the authority and financial resources are adequate for the objective. While it is admitted that on occasion difficulties in competing in remuneration may be a partial explanation, the shortage is attributed mainly to the increasing general demand for scientific and technical staff and to the shortage of scientists and technologists which the Government's plans for the expansion of technological and technical education are intended to relieve.

While those plans are coming to fruition, it is inevitable that the use which is made by the Department of its scientific and technical man-power will be the more closely scrutinized, and the estimate of the distribution of effort given in the present report will be of particular interest. Information supplied to the Advisory Council indicates that over the Department as a whole 25 per cent of effort is being applied to "Advisory work and *ad hoc* investigations", 45 per cent to "Applied Research" and 30 per cent to "Background (or basic research)". A quarter of the Department's effort is thus being spent in helping to ensure that the results of its work are widely known and applied in industry.

The Advisory Council stresses the importance of making every effort to get the results of the work of the Department's establishments widely known in quarters in which they can, and will, be applied to industrial practice, and it would be undesirable to take any steps which would discourage free approach to the establishments by potential users for scientific help to solve their practical problems. Nevertheless, it must be a matter for judgment as to what proportion of the Department's effort should be spent on such advisory and related work, and one which depends to some extent on the position and efficiency of the information services of the country and the existence within the individual industrial firms of those qualified to appreciate the significance of scientific and technological advance and its application to their own processes and problems. To this extent the problem is linked up with that of scientific and technological education.

While the Advisory Council's estimate that 25 per cent of the Department's effort should now be spent on this purpose may well be reasonable, the situation will obviously have to be watched. This the Council proposes to do, in order to prevent undue emphasis on advisory work, to the detriment of new scientific 'capital' for future application. It notes indeed that the establishment and development of information services by trade associations and research associations could be of service here; but it might well have urged the value of developing as a first priority the proposed Science Centre in London, as well as a national library of science and technology and a new science lending library. The regional developments which stem from such national facilities should at least relieve the Intelligence and Information Division of the Department of some of its present work.

The size of the latter Division and the scope of its activities obviously require consideration, not only in relation to the total effort of the Department itself but also in relation to the information services available in Britain as a whole. Since the Advisory Council discussed the functions of the Division in its report for 1952–53, expenditure on the Division has risen from £58,119 in 1952–53 to £71,365 in 1955–56 and to £79,674 in 1956–57; but the staff has changed but little, being given as 80 in 1955–56 and 83 for 1956–57, compared with 76 in 1952–53. The increase is in fact in the range of the smallest, proportional to present numbers, for which the Advisory Council provided in the gradual allocation of the six hundred additional posts for non-industrial staff available for the four years beginning April 1, 1955, coming with the five per cent for building research, seven per cent for forest products research and nine per cent for the National Physical Laboratory. At the other end of the scale are the 112 allocated for mechanical engineering research (an increase of 45 per cent), the increase for hydraulics research being 50 per cent and for radio research 31 per cent.

These distributions were based on the Advisory Council's considered views of how best to distribute resources made available to the Department, and on its assessment of the relative strengths of the needs of the individual stations; it should be noted that even the 9 per cent increase at the National Physical Laboratory represented the second largest allocation of staff—seventy—for the period. Availability of accommodation and the relative ease or difficulty with which special types of staff could be recruited also influenced the allocations ; but it is quite clear from this report that the Advisory Council is well aware that the total man-power demands of the Department have to be considered in relation to those of the country as a whole and that it takes a balanced view of its responsibilities.

The five-year plan has in fact provided a reasonably stable basis on which the various research boards and directors of research can plan their activities for the next few years ; but it is not suggested that it has made it possible for the Department to meet all the requests that it receives. The Industrial Grants Committee, the Scientific Grants Committee and the Nuclear Physics Committee have all pleaded for more money and for priority of claim on departmental reserves, and the Advisory Council also refers to the way in which universities look to the Department to provide the means for initiating new and promising lines of research for which the normal resources of a university are inadequate. Here, however, there arises a further consideration. The resources allocated by the Department in this way call for consideration in relation to Britain's total expenditure on fundamental research. It is not solely within the Department that it is desirable to keep current programmes in accord with available resources, and to review and adjust them constantly to meet changes in the relative importance of different objectives. No accurate information is available as to the proportion of the £34 millions of the vote for universities and colleges in the 1956–57 estimates which is spent upon research ; but the grant for research and development generally in the 1956–57 estimates is increased by some £25 million on last year.

This increase includes industrial as well as academic research ; but the two are not always sharply separated, particularly in the nuclear field, in respect of which misgivings have already been expressed as to the balance of research effort in Britain. The Advisory Council in this report points to the need for unhesitating reduction or elimination of effort on projects less likely to yield valuable results, in order to release resources for new projects, and emphasizes that it is not sufficient to be satisfied that a project is of value. Selection is equally essential if the national research effort is to be in balance, and if the resources of the Department of Scientific and Industrial Research are to be concentrated on the more urgent objectives and those with best prospects of success ; that, it is suggested, is the continuing responsibility of research boards and directors of research. The report does not discuss further this prime difficulty of selection, nor does it suggest that the problem of discontinuing research is being burked in the Department. There is, however, a comment that the boards and directors should be prepared to consider the abandonment of effort in a particular field when that which an establishment is able to make is small compared with what is being done elsewhere.

In this comment there is a clue to the Advisory Council's view of the broad function of the Department's research activities. That effort, it is implied, should in the main be concentrated on lines desirable in the national interest but which otherwise are unlikely to be pursued. It would follow that once research in these fields is firmly established and is being promoted by other bodies, either in industry, independent institutions or universities, government support should be gradually withdrawn. This would in effect make the function of the Department broadly similar to that of the independent foundation such as the Nuffield Foundation or the Carnegie Trust, with the difference, of course, that the Department cannot expect to enjoy quite the same freedom to experiment as the independent institution. Its activities must be more closely aligned to proposals clearly seen to be related to the immediate interests of the nation. It will step in where the independent institution has uncovered a promising lead, and withdraw when it seems a probable and reasonable expectation that other sources will provide the continuing support required.

That does not, however, dispose of the difficulty of the selection of research projects in the first instance or of deciding on the appropriate moment to withdraw or terminate support. It may, in fact, be more difficult for an executive than for an advisory body to make the latter decision, for in the last resort it is the scientist engaged in the project who alone can best judge how near the project may be to success, and even that judgment may easily err. What an advisory body can do is to bring to the notice of those engaged in the project external factors or conditions which may make its success of less concern from a national point of view or warrant handing over the project to some other organization by which it can be continued with greater resources or higher prospects of success. It should not be imagined that any external committee is better able to judge of the prospects of success than those scientists or technologists engaged in the project : all that can be done from outside is to advise, or decide, as to the appropriateness of continuing the project in the national circumstances of the moment.

Judgments as to the prospects of success and as to projects which are most worth while from the point of view of science or technology are best made —and only soundly made—by scientists and technologists themselves, and from that point of view too much stress cannot well be laid on the value of the Department's postgraduate maintenance grants to assist the universities in meeting the national need for trained research workers. These grants may well assume even greater importance as the expansion of technological education proceeds, and here is a further reason for urging that the supervision of technological education should be entrusted to some one body corresponding in functions and status to the University Grants Committee, if indeed the responsibility is too great to be discharged effectively by the latter body.

There is, however, another point at which the work of the Department of Scientific and Industrial Research impinges on technological education, and that is in the work of the research associations. That scheme is now some thirty-eight years old, and ten years ago it was announced that the Government would continue indefinitely its financial contributions through the Department, in the belief that co-operative research is an important means of increasing industrial efficiency but that industry is best fitted to decide what are its own scientific problems and the best means of solving them. The present report from the Advisory Council records at some length the progress and development in the research association movement over the past five years in the light of a report received from its Industrial Grants Committee.

In the first place, the Advisory Council stresses the autonomy of the research associations. Conditions attached to the Department's grants do not materially affect the powers of direction and control possessed by the council of any association, which is elected by the ordinary membership. The terms of government grants to a research association are designed to meet its particular circumstances, including its stage of development; and they are based on information which enables the Industrial Grants Committee to judge both the suitability of an industry for co-operative effort and the extent to which encouragement is justifiable in the national interest. The grant to be recommended is then assessed, after considering the programme of research, its significance to the industry, its cost and the scientific status of the association in question.

It may, of course, be objected that this is done from outside the industry, and that it is at variance with the belief expressed above that an industry is best fitted to decide what are its own scientific problems and the best means of solving them. No research association, it is true, can hope to select problems for investigation with the same certainty as to their industrial importance as the individual firm; but it can judge those likely to possess national importance as well, and it may promote the attack on problems which are better handled in collaboration and do not involve an element of competition. Moreover, the developments of the past five years indicate also the value of the research association as a means of distributing benefits to an industry and encouraging the attack on more general problems such as operational research, methods of quality control, the study of consumer needs and human factors in industry. During this period, the research associations have received under the Technical Assistance Programme of the United Nations Economic Co-operation Administration, later the Mutual Security Agency, and now the International Co-operation Administration, allocations amounting to about 800,000 dollars for equipment, 30,000 dollars for the provision of current and back numbers of books and periodicals to fill gaps in their information and library services, and 7,600 dollars for visits to the United States by scientific and technical teams to obtain information. They are at present receiving further assistance from the United States under 'Conditional Aid' for the promotion of productivity.

The work on human relations in industry and on individual efficiency in industry, much of which is financed by grants received under the Conditional Aid Scheme for the use of Counterpart Funds derived from United States Economic Aid, adds a fourth category to the three main fields of activity of the research associations, and the Advisory Council recognizes the need to pursue this type of work. The Conditional Aid Programme is due to end on, or shortly after, June 1956, and the Advisory Council suggests that increased resources should be made available for such research, and that it should not be undertaken merely at the expense of the older types of work. Careful consideration is being given to the possible basis of a long-term programme of work in this field financed from departmental funds.

Such work in itself is related to technical education, in that some of it is specifically concerned with the removal of misunderstandings and other difficulties which attend the introduction of new processes and new products or materials in industry. Besides this, the part which the research associations might play in support of technological and technical education was touched upon as a conference in June 1951 and was the sole subject of a conference held in November 1953, as a result of which the ties between individual research associations and technical colleges have been strengthened. The contribution which the research associations might make to technical and technological education is being increasingly recognized, though it was overlooked in the recent White Paper on Technical Education. Probably it is in promoting the recruitment of scientific and technical staff by an industry, as well as in making an industry more research-minded and receptive of new ideas, that the research associations exercise their major educational influence. Nevertheless, Dr. P. F. R. Venables did well to emphasize, in his recent book, the value of a greater interchange of staff between the technical colleges and research associations, as well as industry generally.
